M.DCCC.XXX.

THE

EDINBURGH ENCYCLOPÆDIA.

COLUMBUS, or Colon, Christopher, the well-known discoverer of America. He was a citizen of the republic of Genoa, and born in the year 1447. The exact place of his birth has not been ascertained;* and it is only by inference from certain statements made by Columbus himself, in the letters which he addressed to Ferdinand and Isabella, the rulers of Spain, that the date of his nativity has been obtained with any measure of correctness. These letters are preserved in the life of the Genoese navigator, written by Don Ferdinand his son. In one of them Columbus informs the exalted persons to whom he addressed himself, that at the time he wrote A. D. 1501, he had been engaged nearly forty years in the profession and life of a seaman; and in another letter he states, that he went to sea so early as the age of fourteen. The statements in both instances are deliberately made by Columbus himself; there is no reason therefore to doubt their accuracy, or to dispute the inference that this illustrious navigator was born in the year 1447.

The family from which Columbus was sprung had betaken themselves, for several generations, to a sea-faring life, and, as it appears, with very little emolument or success; for the immediate parents of the navigator seem to have been in indigent circumstances at the time of his birth. They were able, however, in one way or another, to give to Columbus such an education, as fitted him for the profession, in which, after the example of his ancestors, he was about to engage. Besides the more necessary branches, they had him instructed in geometry, astronomy, and cosmography, and in the art of drawing; in every thing, in short, which was held to be requisite or proper at that time, to form a skilful and successful adventurer upon the seas. Such an education must have been attended with considerable expence; but so little of the early life of this extraordinary man is known, that we have not the means of ascertaining how the expence was defrayed, whether by assistance of wealthy relatives, or whether the young Columbus was so fortunate as to meet with a patron, at once decerning enough to mark the indications of his genius, and able as well as willing to support him, during the prosecution of his studies.

Columbus was not one of those whose abilities remain concealed till late in life, and who, after a youth spent in idleness or vice, or sleepy stupidity, have awakened, at a more advanced age, in all the ardour and activity of genius. Having chosen his profession, he hastened to qualify himself for the honourable discharge of its duties. He is said to have imbibed the instructions of his teachers with a surprising quickness: He speedily mastered the Latin tongue, and attained to a competent knowledge of geometry, astronomy, and the theory of navigation. At the age of fourteen, as we have already stated, he went to sea. He made his first voyages to those parts of the Mediterranean which were frequented by his countrymen the Genoese, trading with the inhabitants, and satisfied, as it seems, for a time, with the gains of reputable merchandise. But the ardour of his mind was not to be repressed, and a prouder career and a higher destiny awaited him. When not older than twenty, he undertook a voyage of curiosity, or rather of discovery; for so perhaps we might be permitted to call it, as one object which he had in view undoubtedly was, to ascertain whether the frigid zone was habitable. Accordingly he stretched into the northern seas, ran along a part of the coast of Iceland, the limit and extremity of former enterprises, and pushed into the ocean which lies beyond the arctic circle. "In February 1647," says he, in a memorandum upon the subject, "I sailed 100 leagues beyond Thule or Iceland, the northern part of which is 73 degrees distant from the equinoctial, and not 63 degrees as some suppose; neither does it lie upon the line where Ptolemy begins the west, but considerably more to the westward. To this island, which is as large as England, the English carry on a trade, especially from the port of Bristol. When I was there the sea was not frozen, but the tides were so great, that in some places they rose and fell 26 braccios (about 45 feet). I have likewise been in the Portuguese fort of St George del Mina, under the equinoctial, and can witness that it is not uninhabitable, as

* Before Columbus received his commission from Ferdinand and Isabella, he usually designed himself *Columbus de Terra Rubra.*

some have supposed." *Life of Columb.* Churchill's *Voyages*, vol. ii. In this voyage, the fortune of Columbus, as a merchant, was not increased in any remarkable degree, but he derived from it a large accession of skill and experience in the nautical art; and he now began, perhaps for the first time, to taste the sweets of reputation, and to know something of the inexpressible pleasure which results from the assurance of having done what no one has ever executed or even attempted before. The next adventure of Columbus which his biographers have recorded, was of a kind somewhat different. Not long after his return from the northern ocean, he appears to have entered the service of *Columbus junior*, as he was called, a famous sea-captain of those times, but in what capacity our adventurer was employed, we have not been able to learn. The officer alluded to, who was of the same family as well as of the same name with the discoverer of America, commanded a small squadron fitted out at his own expence, and carried on a piratical warfare against the Venetians and the Turks, the rivals of the Genoese at this period, in the commerce and the sovereignty of the Mediterranean. In the service of the captain just mentioned, Columbus established his character, not only for skill and dexterity in naval affairs, but also for courage. His valour was tried in many severe conflicts, and his life often exposed to danger. On one hazardous occasion in particular, he escaped with great difficulty. Having attacked, along with the rest of the fleet under the orders of his relative, some Venetian galleys which were returning, deeply and richly laden from the coast of Flanders, in the ardour of the combat, he grappled with one of the enemy's vessels, and in this situation, fast locked to his antagonist by means of strong iron hooks and chains, the ship in which he served unfortunately took fire. In a moment, all was terror, and outcry and confusion. But Columbus, distinguished as much by his coolness and presence of mind, as by his bravery in action, threw himself into the sea, and partly by swimming, and partly by the support of an oar which he found accidentally within his reach, got safe to land. This engagement took place not far from the harbour of Lisbon, and the distance between the vessel and the shore is said to have been more than two leagues.

Quitting the dangerous, and judging by our ideas of piratical warfare, the less honourable service of his relative, Columbus, as soon as his health was established, repaired to Lisbon. The encouragement given by Don Henry of Portugal, to every person at all skilled in the art of navigation, and animated with the love of discovery, was at this time exceedingly great. To Columbus, therefore, still young, ardent, enterprising and active, the service of the Portuguese appeared every way desirable. He readily yielded to the solicitations of his friends, and consented to fix his residence in Lisbon; and having about the same time married a Portuguese lady, by name Donna Felipa Moniz Perestrello, he seems to have considered himself as a regular and recognised subject of Portugal. Nor did the circumstance of his marriage either detach him altogether from sea affairs, or suppress within him the desire of honourable reputation. The lady in question was the daughter of Peter Moniz Perestrello, himself a sailor, and one who had been employed in the earlier navigations of Don Henry, and had discovered, under the license and patronage of that prince, the islands of Puerto Sancto and Madeira. In the eye of Columbus, therefore, a connection with such a family appeared not only highly reputable in itself, but likely to be of essential service to him in his future pursuits. By means of his wife, he got possession of the journals, sea-charts, and other papers which had belonged to her father Perestrello; and he easily learned from them what object the Portuguese rulers had in view in prosecuting their navigations towards the south. This object was nothing else than to discover a passage to the East Indies, in order to secure to their country the profitable commerce with the spice islands, which had hitherto been engrossed by the Venetians: And it was proposed to reach those distant parts by sailing round the continent of Africa, or at least by doubling its most southern cape.

After Columbus had made himself acquainted with these and other particulars, the thought of finding a shorter and safer passage to the East Indies, appears gradually to have arisen in his mind. In the discovery of the New World, little is to be ascribed to accident, or to any thing bearing the name and character of accident. It was the result of diligent enquiry and patient comparison; it was a conclusion attained by successive steps and profound and elaborate reflection; the legitimate issue of those rational faculties which the Almighty has implanted in man; the exclusive property, as well as the boast of our intellectual nature. The rotundity of the planet on which we live was known. Upon the authority of the ancients, an authority highly respected and valued in the 15th century, it was believed that the ocean encompassed the whole earth, and in particular that it extended in a direction from east to west, between the coast of Spain lying nearest the Atlantic, and the shores of India. Marco Polo, a noble Venetian, and other travellers of modern times, had asserted, that the countries which they had visited beyond those of Persia and India, and to which they gave the names of Cathay and Zipango, stretched out in a wonderful manner towards the east. The inference therefore was, and Columbus readily drew it, that in proportion as those countries extended towards the east, they must approach what we should now call the western longitude, or pass into it altogether; and, therefore, that to sail directly west, was the shortest as well as the most obvious and certain course, in order to reach them. This result was strengthened, in a great degree, by the errors into which the ancient geographers had fallen, with regard to the countries situated beyond the eastern limit of the Persian empire. They had placed these countries much farther from the first meridian which passed through the Fortunate Islands, than their real position. According to Marinus Tyrius, one of the most distinguished of the ancient geographers, the country of the Sinæ, or Chinese, was situated at no less a distance from the meridian alluded to, than 15 hours, or 225 degrees: And beyond the Chinese lay the kingdoms of Cathay and Zipango, extending still farther in an easterly direction. The conclusion, therefore, from the whole, seemed to be irresistible and sure, that the countries in question might be visited by sailing in a westerly course: and, moreover, that these countries would actually be found to lie within a distance, by no means considerable, from the Canary Islands, or even from the coast of Africa.

In the conclusion now mentioned, Columbus was still more firmly established, by the communications which he had with his cotemporary Paul, a physician of Florence, a man well known for his acquaintance with geometry and cosmography, and for his inquiries into the results, whether certain or only probable, which had followed from the Portuguese navigations. This learned person stated several facts in confirmation of the

Columbus. scheme suggested by Columbus, pointed out the course of sailing on a chart which he sent to the navigator, urged him strongly to secure the proper means in order to the execution of his purpose, and concluded by saying "that the voyage laid down, was not only possible, but true, certain, honourable, advantageous, and most glorious among Christians."

The next step of Columbus was to engage some of the European powers in the accomplishment of his object. But the difficulties which he experienced while soliciting at the courts of kings, the patronage which he at length obtained, the progress of the voyage, and the actual discovery of the American continent, have already been treated of in another part of this work. See AMERICA. It remains, therefore, only to add a few particulars relative to the subsequent history of the Genoese navigator.

During his return from the countries which he had visited, a severe tempest overtook the fleet, so that the life of the admiral was exposed to extreme danger. The wind, which had for many days been moderate, as well as favourable, now suddenly rose in great violence, and blew with the fury of a hurricane, while every thing which naval skill or long experience could suggest, was anxiously tried, in order to save the ships. The mind of Columbus, too, was harassed with the fear, lest all knowledge and memory of his discoveries should be for ever lost, and the human race be deprived of the advantages which he had no doubt would result from an intercourse with the inhabitants of the western world. Nor was he without a reasonable concern for his own reputation, dreading it as the worst evil that could befal him, to be handed down to posterity in the character of a bold but visionary projector, whose time had been spent, and whose life had been thrown away, in the pursuit of unattainable objects. The fury of the storm increased, and no hope of safety seemed to remain. In these circumstances, Columbus bethought himself of an expedient, most proper in itself, and every way advisable, as it must appear when once pointed out, but which perhaps would not readily have occurred to any one possessed of less composure and presence of mind. He instantly retired to his cabin, and wrote upon parchment a short account of his voyage and of his success. This writing he folded up and sealed, addressing it to their Majesties the King and Queen of Spain; and having ordered a large cask to be brought to him, he wrapt the parchment in oiled cloth, surrounded it on all sides with wax, and inclosed it in the cask: and carefully stopping up this last, he threw the whole into the sea. Nor was he satisfied with one packet of the kind which we have just described; he immediately prepared another similar to the first, and attached it to the poop of the vessel, that, as he expresses it himself "when the ship sunk, the cask might float upon the water, and take its chance of being found." *Life of Columbus*, Churchill's *Voyages*, vol. ii. Happily, however, the storm at length abated; and not many days after, Columbus entered the port of Palos, from which he had sailed about seven months before, amidst the acclamations and the wonder of the multitude, who had perceived the vessel at a distance, and who waited his approach.

The commission under which Columbus agreed to undertake the voyage of discovery, invested him with high powers, and secured to him many important privileges. From the beginning he had stipulated, "That he should be admiral on the ocean of all the seas and lands which he might discover, with all the allowances, privileges, and prerogatives enjoyed by the admirals of Castile and Leon, in their several seas: That all civil employments, as well of government as in the administration of justice, should be entirely at his disposal, in all the islands and continents which he was to discover: That all governments should be given to one of three persons to be named by him; and that he should appoint judges in all parts of Spain trading to the Indies, to decide upon all causes relating to that trade and to those parts." These conditions, and others, which our limits prevent us from stating, were the more readily agreed to by Ferdinand and Isabella, while the scheme of Columbus remained as a matter of speculation, and before the discovery of the western continent was actually made. But no sooner was it ascertained, that countries hitherto unknown had really been visited, and occupied in the name of the Spanish monarchy, than it was perceived that the commission was too ample, and the powers and privileges too many and great. Such a commission, however, had been granted, and it could not openly or immediately be revoked. The mind of Ferdinand, though cultivated in some degree, was neither strong nor comprehensive. His temper was suspicious and peevish; and unfortunately, his ear was open to the insinuations of the enemies of Columbus. Less gold had been obtained from the countries newly occupied, than the avarice of the monarch had led him to expect. Indeed the conquests actually made, had never defrayed the expense of securing and maintaining them. Disturbances likewise had arisen in the colony of Hispaniola; and though these disturbances had been quelled by the presence of Columbus and by powerful aid from Europe, still the very existence of such disturbances, lessened, in the mind of Ferdinand, the hope of undeviating prosperity, which he had universally permitted himself to entertain, and rendered his temper yet more suspicious and fretful. Complaints of the misrule of Columbus were daily brought to him; and in the moment of irritation, this capricious monarch, granted a commission to Francis de Bovadilla, a knight of the order of Calatrava, empowering him to proceed to Hispaniola, to inquire into the conduct of the admiral, and upon finding him guilty, or even upon finding any plausible reason for a charge against him, to take upon himself the government of the island. The result was exactly what might have been expected, from a commission so utterly preposterous and unjust. Materials for a charge against Columbus were collected; every sort of information, even from persons the most infamous, was greedily received, and the admiral, now advanced in years but still unbroken in spirit, was loaded with irons, and hurried on board a ship. The charge was then drawn up according to the forms of law; and the discoverer of the western world was sent to Europe, in order to be tried for his offences, real or supposed, by the government at home.

It is not easy to read the account of this infamous proceeding with any measure of patience. It was not believed, even by the tyrannical Bovadilla himself, that Columbus had abused, in any one respect, the authority or the privileges of the situation in which his sovereign had placed him. His life, as a subject of the Spanish crown, was that of uniform obedience and unwearied activity. And his whole conduct was such as to gain, not only the esteem, but the enthusiastic admiration and praise of every one who had the opportunity and the means of becoming acquainted with it. In consequence of this opinion and belief, Alonzo de Vallejo, the captain of the vessel on board of which Columbus was confined, Columbus. approached his prisoner, immediately after they had quitted the island, with feelings of the highest veneration and the deepest regret, and offered to release him from the fetters with which he was bound. "No," said Columbus, in a burst of generous indignation, "I wear those irons in consequence of an order from their majesties the rulers of Spain. They shall find me as obedient to this, as to their other injunctions. By their command I have been confined, and their command alone shall set me at liberty." He never forgot the unjust and shameful treatment which he had received. Through the whole of his after life he carried the fetters with him wherever he went, as a memorial of the ingratitude of his country: he hung them up in his chamber, and at last gave orders that they should be buried with him in his grave.

Upon the arrival of Columbus in Spain, a prisoner and in fetters, the indignation of all men was highly excited, and Ferdinand himself, cold and distant and haughty as he was, felt, for a while, the emotions of shame. He ordered Columbus into his presence, disclaimed all knowledge of his imprisonment, and soothed him with kind words and promises. But after detaining him at court for a long time in fatiguing attendance and fruitless solicitation, he appointed Nicholas de Ovando, a knight of the order of Alcantara, governor of Hispaniola in his stead. Such was the reward which Columbus received, for having devised and carried on to a successful issue, the most noble enterprise which has ever entered into the mind of man; and such is the account which impartial history is constrained to give of the justice and the gratitude of kings!

But though unwilling to restore Columbus to his place and the honours connected with it, Ferdinand and Isabella were still desirous to employ him in new enterprises by sea. He made in all four voyages to the western continent. He discovered the main land of America, and sailed along the coast from Cape Gracios a Dios to the harbour of Portobello. It was in the neighbourhood of the place last mentioned, that he gained, for a time, an astonishing command over the Indians by predicting an eclipse of the moon. At length, after a considerable variety of fortune, he returned to Spain; and worn out with many years, and fatigue, and disappointment, and sorrow, he died at Valladolid, on the 20th of May, 1506. His funeral, by the orders of Philip, who ascended about this time the throne of Castile, was extremely magnificent, and the following inscription was engraven upon his tomb:

A CASTILIA YA LEON
NUEVO MUNDO, DIO COLON.

Columbus || Comedy.

COMETS.

Comets. IN the article ASTRONOMY, Vol. II. pp. 674, 695, 814, we have already treated of the subject of comets, and we shall now lay before our readers such further information as may appear necessary upon this important subject.

General phenomena of comets. When examined through a good telescope, a comet resembles a mass of aqueous vapours encircling an opaque nucleus of different degrees of darkness in different comets, though sometimes, as in the case of several discovered by Dr Herschel, no nucleus can be seen. As the comet advances towards the sun, its faint and nebulous light becomes more brilliant, and its luminous train gradually increases in length. When it reaches its perihelion, the intensity of its light, and the length of its tail, reach their maximum, and sometimes it shines with all the splendour of Venus. During its retreat from the perihelion, it is shorn of its splendour, it gradually resumes its nebulous appearance, and its tail decreases in magnitude till it reaches such a distance from the earth, that the attenuated light of the sun, which it reflects, ceases to make an impression on the organ of sight. Traversing unseen the remote portion of its orbit, the comet wheels its ethereal course far beyond the limits of our system. What region it there visits, or upon what destination it is sent, the limited powers of man are unable to discover. After the lapse of years, we perceive it again returning to our system, and tracing a portion of the same orbit round the sun, which it had formerly described.

Opinions respecting comets. It would be a waste of time to detail the various wild and extravagant opinions which have been entertained respecting these interesting stars. During the ages of barbarism and superstition, they were regarded as the harbingers of awful convulsions, both in the political and in the physical world. Wars, pestilence, and famine, the dethronement of kings, the fall of nations, and the more alarming convulsions of the globe, were the dreadful evils which they presented to the diseased and terrified imaginations of men. As the light of knowledge dissipated these gloomy apprehensions, the absurdities of licentious speculation supplied their place, and all the ingenuity of conjecture was exhausted in assigning some rational office to these wandering planets. Even at the beginning of the 18th century, the friend and companion of Newton regarded them as the abode of the damned. Anxious to know more than what is revealed, the fancy of speculative theologians strove to discover the frightful regions in which vice was to suffer its merited punishment; and the interior caverns of the earth had, in general, been regarded as the awful prison-house in which the Almighty was to dispense the severities of justice. Mr Whiston, however, outstripped all his predecessors in fertility of invention. He pretended not only to fix the residence of the damned, but also the nature of their punishment. Wheeled from the remotest limits of the system, the chilling regions of darkness and cold, the comet wafted them into the very vicinity of the sun; and thus alternately hurried its wretched tenants to the terrifying extremes of chilling cold and devouring fire.

By other astronomers, comets were destined for more scientific purposes. They were supposed to convey back to the planets the electric fluid which is constantly dissipating, or to supply the sun with the fuel which it perpetually consumes. They have been regarded also as the cause of the deluge; and we must confess, that if a natural cause is to be sought for that great event, we can explain it only by the shock of some celestial body. The transient effect of a comet passing near the earth, could scarcely amount to any great convulsion; but if the earth were actually to receive a direct impulse from one of these bodies, the consequences would be awful. A new direction would be given to its rotatory motion, and the globe would revolve round a new axis. The seas, forsaking their ancient beds, would be hurried by their centrifugal force, to the new equatorial regions; islands and continents, the abodes of men and animals, would be covered by the universal rush of the waters to the new equator, and every vestige of human industry and genius at once destroyed. The chances against such an event, however, are so very numerous, that there is no dread of its occurrence.

Opinions respecting the tails of comets.

Various opinions have been entertained by astronomers respecting the tails of comets. They were supposed by Appian, Cardan, and Tycho Brahe, to be the light of the sun transmitted through the nucleus of the comet, which they believed to be transparent like a lens. Kepler thought, that the impulsion of the solar rays drove away the denser parts of the comet's atmosphere, and thus formed the tail. Descartes ascribes the tail to the refraction of light by the nucleus. Newton maintained, that it is a thin vapour raised by the heat of the sun from the comet. Euler asserts, that the tail is occasioned by the impulsion of the solar rays driving off the atmosphere of the comet; and that the curvature observed in the tail is the joint effect of this impulsive force, and the gravitation of the atmospherical particles to the solid nucleus. Mairan imagines that comets tails are portions of the sun's atmosphere. Dr Hamilton of Dublin supposes them to be streams of electric matter; and Biot supposes with Newton, that the tails are vapours produced by the excessive heat of the sun; and also, that the comets are solid bodies before they reach their perihelion; but that they are afterwards either partly or totally converted into vapour by the intensity of the solar heat.

Defence of Euler's theory.

Of all these theories, that of Euler seems to be most philosophical. Since the comets are composed chiefly of nebulous matter, and have very large atmospheres, the external atmospheric strata must be drawn towards the comet by very slight powers of attraction, and will therefore yield to the smallest impulse. From the great density of the planets, on the contrary, and the small size of their atmospheres, the external strata are attracted towards them with a very great force, and therefore cannot yield, like those of the comets, to a slight impulse. Hence we see the reason why the comets have tails, while none of the planetary bodies exhibit such a phenomenon. Whatever opinion may be entertained of this explanation, it must, at least, be admitted, that if light is a material substance, the atmospherical particles of a comet may have their gravity diminished to such a degree, either by their distance from its centre, or by the rarity of the nucleus, as to yield to the impulse of the solar rays, and be forced behind the nucleus, in the same manner as smoke yields to the impulse of the gentlest breeze.

If this theory is well founded, may we not form an opinion of the density of comets, by comparing their magnitude with the length of their tails; and may we not suppose, that those comets which have no tails are more dense than others, and exercise over the particles of their atmosphere an attractive force, which enables them to resist the impulse of the solar rays.

Dr Brewster's theory of the loss of the comet of 1770.

In the article ASTRONOMY, p. 675, we have already noticed the peculiarities in the motion of the comet of 1770, which we attributed, along with other astronomers, to the disturbances which it had experienced from the action of the planets. As we are convinced, however, that this explanation is too vague and general to be satisfactory, we shall now lay before our readers the theory of the singular phenomena of the comet of 1770, as recently proposed by Dr Brewster. This theory, while it seems to give a rational explanation of these phenomena, affords, at the same time, a plausible solution of some other difficulties in astronomy.

A comet appeared in the year 1770, and was carefully observed for nearly four months by M. Messier. When Prosperin and Pingrè applied themselves to calculate the elements of its orbit, they found that a parabolic path would not represent the observations of Messier, and hence they suspected that its orbit might be sensibly elliptical. M. Lexell of St Petersburgh computed its elements in an elliptical orbit, and he found that its period was five years and a half, and that its greatest distance from the sun did not much exceed that of Jupiter. This curious subject was investigated rather unsuccessfully by Slop, Sejour, and Lambert; and a few years ago it attracted the particular notice of the National Institute of France. At the request of that learned body, Dr Burckhardt repeated all the calculations with the utmost care, and the result of his investigations was a complete confirmation of Lexell's conclusions.

Here then is a most singular anomaly in the motion of this comet. While all the other comets which have been observed, move in orbits stretching far beyond the limits of the solar system, and revolve in periods of long duration, the comet of 1770 never wanders beyond the orbit of Saturn, and completes its revolution in the short period of five years and a half. The return of this body, therefore, was confidently expected by astronomers; but though it must now have completed nearly eight revolutions round the sun, and though more observations have been made in the heavens during the last 40 years than perhaps during the two preceding centuries, yet the comet of 1770 has never re-appeared. We are consequently entitled to conclude, that the comet of 1770 is lost, which could happen only from its uniting with one of the planets, whose orbits it crossed. Now, if such an union took place, two consequences would obviously flow from it. The planet would suffer a sensible derangement in its motions, and its atmosphere would receive a vast accession of that nebulous matter, of which the comets are often wholly composed. Here, then, we have two distinct criteria to enable us to ascertain the individual planet by which the comet was attracted. The path of the comet intersects the orbits only of Venus, the Earth, Mars, the four new planets, and Jupiter, and therefore it must have united with one of these bodies, or with their satellites. Now, since the year 1770, neither Venus, the Earth, Mars, nor Jupiter, have suffered the smallest derangement of this kind, nor have they received any visible addition to their atmospheres. We must, therefore, look to the four new planets for some indication of the presence of a comet, and if they exhibit any phenomena that are unequivocally of this description, we must consider such a coincidence as a strong proof of the theory, or as one of the most wonderful facts in the history of science.

Two of the new planets, Ceres and Pallas, exhibit, in the form and position of their orbits, evident marks of some great derangement; but as this may have arisen from that explosive force, by which they seem to have been separated from a larger planet, (see ASTRONOMY, p. 641,) we are not entitled to regard it as a proof of the present theory. But though we cannot employ our first criterion either for or against the theory, the second applies with irresistible force, and we would entreat the particular attention of our readers to this single point. The two planets Ceres and Pallas, are actually surrounded with atmospheres of an immense size. The atmosphere of Ceres is 675 English miles high, while that of Pallas rises to the height of 468 miles. Now the height of any of these atmospheres is greater than the united heights of the atmospheres of all the other planets, and is above a thousand times higher than it ought to have been, according to the ratio which exists between the globes and the atmospheres of all the other bodies of the system. Astronomers were so forcibly struck with the magnitude of these atmospheres, that a dispute arose whether Ceres and Pallas should be called planets or comets, and the discussion terminated, by giving them the name of asteroids, a class of bodies which were supposed to partake of the nature both of planets and comets. But to draw this argument still closer upon the subject, let us enquire from what other source these atmospheres could be derived, if they were not imparted by the comet of 1770. If the four new planets are the fragments of a larger body, endowed with an extensive atmosphere, each fragment would obviously carry off a portion of atmosphere proportioned to its magnitude; but two of the fragments, Juno and Vesta, have no atmosphere at all, consequently the atmospheres of Ceres and Pallas could not have been derived from the original planet, but must have been communicated to them at a period posterior to the divergency of the fragments.

It would have been a satisfactory addition to the preceding arguments, if we had been able to shew, by direct calculation, that Ceres and Pallas were at the same instant with the comet in that part of their orbits which was crossed by its path, and that the position of the planes of the orbits was such, as to permit a near approximation. But as we have no data sufficiently correct for such a calculation, we must leave this part of the subject to some future opportunity. There is one fact, however, which in some measure supplies its place, and which is therefore worthy of particular notice. The nodes of the comet of 1770, lie exactly between the nodes of Ceres and Pallas, an arrangement which is absolutely indispensible to the truth of the preceding theory.

We shall now conclude this article with three Tables, containing 1st, The parabolic motion of comets in an orbit, whose perihelion distance is equal to the mean distance of the earth from the sun; 2d, The parabolic descent of comets towards the sun in a right line; and, 3d, The elliptic motion of comets. Although these Tables occupy more room than we could have wished to allot to this subject, yet as they were never before published in any English work, and as they are extremely useful and important to astronomers, we have presented them in as abridged a form as possible.

TABLE I. *Of the Parabolic Motion of a Comet, whose Perihelion Distance is equal to the Radius of the Earth's Orbit.*

EXPLANATION OF THE TABLES.

Table I.

Explanation of Table I.

The use of this Table is to find the course of a comet, whose perihelion distance is equal to the radius of the earth's orbit. The first column contains the number of days since the comet passed its perihelion;—the second column contains the true anomaly of the comet, reckoned from the perihelion;—and the third column, the differences.

In order to adapt the Table to other parabolic orbits of any form, let the radius of the earth's orbit $= 1$, and the perihelion distance of the new orbit $= x$. Then if we multiply the number of days since the comet passed its perihelion in the first column by $x^{\frac{3}{2}}$, and enter the Table with this new number of days, we shall find in the opposite column the true anomaly corresponding to the given orbit.

On the contrary, if we wish to find from the given time after the passage of the perihelion, the time in the Table, and from this the true anomaly, we must divide the given time by $x^{\frac{3}{2}}$, in order to obtain the time in the Table.

Example.—If we suppose the perihelion distance of a comet to be $0.5835 = x$, and that its true anomaly is required 49 days, 18 hours, 55′ and 16″ after its passage of the perihelion. Then reducing the hours and minutes, &c. to decimals of a day, we shall have

$$\frac{49.78837}{(0.5835)^{\frac{3}{2}}} = 111.7034 \text{ days},$$

which may be found by logarithms in the following manner:

Log. of the perihelion distance 0.5835 . . .	9.7660409
Half of this logarithm	9.3830204
Three halves of the log. of the perihel. distance	9.6490613
Which being subtracted from 49.78837 days	1.6971279
There remains the log. of 111.7034 days . .	2.0480666

With 111.7034 days enter Table I. and corresponding to it will be found 90° 38′ 57″.4, the true anomaly of the comet 49.78837 days before and after its passage of the perihelion.

Table II.

Explanation of Table II.

The second Table is computed for the parabolic orbit of a comet whose perihelion distance is $= 0$, or whose orbit is a straight line. The first column contains the distances, the second and fourth the time, and the third the differences.

This Table is of very general use for all parabolic orbits, and serves to find the time in which a comet describes a given arch, when we know only the three sides of a triangle formed by lines drawn from the sun to the two extremities of the arch. One of these sides is the chord of the arch which we shall call c, and the other two sides which may be called a and b, are the radii vectors, or the distances of the comet from the sun. With these numbers find the values of

$$\frac{a+b+c}{2} = m$$

$$\frac{a+-c}{2} = n$$

With these values of m and n enter Table II. and take out the time from the second and fourth columns, and the difference of the times thus found is the time in which the comet would describe the given arch of a parabola.

Example.—Let $a = 1$; $b = 1$; $c = 2.2361$, then

$m = \dfrac{a+b+c}{2} = 2.61805$ which gives

in the Table	116.084 days

$n = \dfrac{a+b-c}{2} = 0.38195$ which gives

in the Table	6.467 days
	109.617 days

Hence the time in which the arch c is described is 109.6117 days, or 109 days, 14 hours, 48′.

In this Table the cubes of the numbers in the first column are proportional to the squares of the numbers in the second and fourth.

Comets ‖ Comma.

Explanation of Table III.

Table III.

This Table is computed for the elliptical orbits of comets, as the last was for parabolic orbits. The greater axis of the ellipse, determined in parts of the radius of the earth's orbit, is supposed to be known, and from this we may easily find, by the Table, the time of a revolution in days and decimals of a day.

The greater axis of the elliptical orbit is expressed in the following Table by 1000, and the time of a half revolution by 500,000, so that the time of a whole revolution will be 100,000. We have then only to make the following proportions:

1. As 1000 is to the greater axis of the elliptical orbit of the comet, so is the number contained in the first column of the Table to a fourth proportional, which will be the distance of the comet from the sun in parts of the radius of the earth's orbit.

2. As 100,000 is to the time of a complete revolution of a comet, so is the number contained in the second column of the Table to a fourth proportional, which will be the time, corresponding to the distance, expressed in days and decimals of a day.

Example.—Let the greater axis of the elliptical orbit of a comet be 6.287, and the time of a complete revolution 5.575 years, which was the case with the famous comet of 1770, the only one which is known to have moved in an elliptical orbit, and let the distance be 12, then we have

$$1000 : 6.287 = 12 : 0.075404,$$

the distance of the comet from the sun in parts of the radius of the earth's orbit; and

$$\text{Years.}\quad 100000 : 5.575 = 280 : 0.01561,$$

which is 5 days, 16 hours, 44′, the time which has elapsed since its passage of the perihelion, or the time which will elapse before it reaches its perihelion.

The preceding Tables were principally computed by M. Schulze. (*o*)

COMETARIUM, is the name of a machine invented by Dr Desaguliers, for explaining the phenomena of the motions of comets. The fullest and most perspicuous description of this machine will be found in Ferguson's *Astronomy*, vol. ii. p. 17.

COMETES, a genus of plants of the class tetrandria, and order Monogynia. See Botany, p. 126.

COMMA, in Music, is a name very anciently applied to the interval which is the difference between the major and the minor tone, and which is still very often used alone, without further addition, in musical writings; but which is not a commendable practice, for want of precision, since two other small intervals very often occur that pass also by this name, viz. the minor comma, and that of Pythagoras, besides a multitude of others, of less frequent occurrence or use, which different writers have called commas, as in the Table thereof which we have subjoined.

Comma *Major*, or *Comma* (*c*), is an interval whose ratio is $\frac{80}{81}$; the component primes of which are $\frac{2^4 5}{3^4}$; its common logarithm is .9946049,6811: in the binary logarithms of Euler, or decimal of an octave, it is .0179219O: it is the unit of the comma logarithms: where the schisma is the unit, it is = 11.0078624: in the new notation it is 11Σ + *m*: in the elements of perfect tune, it is = € + Σ: in diatonic elements, T—t, as before observed: in chromatic elements, 𝕊—𝒮: and in concordant, or tunable elements, it is 2 3^ds^ + III—2 4^ths^; where, on such an instrument as Mr Liston's organ, it may be correctly tuned, as it may more readily, and indeed is, in numerous instances on that organ, by 3 V—VIII—VI, by the help of perfect intervals only.

Comma.

The following equations exhibit the value of the *major comma*, in terms of all the several intervals in the Table, Plate XXX. of Vol. II. viz.

c = 11Σ + m
= € + Σ
= R + ƒc

c = T — t
= đ — Σ
= Ɛ — €

= ƒ — D
= D — χ
= π — ƒ€
= ∂ — π
= III — 2t

c = 10Σ + 3f + d
= 10Σ + f + F
= 5Σ + f + R
= 3Σ + r + R
= 2Σ + χ + R

c = 23Σ + 2m — đ
= 21Σ + 2m — €
= Σ + ƒ — π
= π + f — 2
= R + π — €
= Ɛ + π — ƒ
= Σ + φ — f
= R + ℝ — f
= Ɛ + f — φ
= F + φ — m
= P + S — T
= € + χ — r
= d + r — χ
= 11d + 33f — 10m
= 𝕋 + € — 2S
= 23 + III — 24

c = t — 2𝒮 — €
= ƒ — r — đ
= ſ — π — R
= 2Σ — π — r
= D — f — 3Σ
= π — f — 4Σ
= π — χ — Σ
= 2Ɛ — ƒ — R

By the help of this Table, the major comma can readily be expressed in any notation of three intervals, or of two when practicable. This interval is called the greater, syntonic, or elementary comma of various writers. It is also called a schism, or schisma, by Des Cartes, Holder, and others. It is the minor comma of Kollmann; and it is the enharmonious interval of Wood and Gregory. Intervals which are increased, sharpened, or made more acute by this interval (*c*), are said to be *acute*, and are marked with the acute accent (′), as an acute major third III′, by Overend, Maxwell, Liston, Farey, &c.; and intervals that are decreased, flattened, or made more grave by this interval (*c*), are said to be *grave*, and are marked with the grave accent (\`), as a grave minor third 3\`. These same marks, when affixed to letters of the scale, imply also the same thing, as A′, B\` are read A *acute*, B *grave*, &c. Chambers marks the acute and grave of intervals, or letters, by a dot placed over or under them, thus IİI, III, Ȧ, B, but which is far inferior in convenience to the above. By the same author, our grave or acute intervals are said to be *deficient* or *redundant* intervals. In our nomenclature, after Mr Overend, such are said to be *comma-deficient*, or *comma-redundant* intervals. M. Henfling calls our grave or acute intervals *inconcinnous ones*.

In his *Harmonics*, prop. 8. cor. 4. Dr Robert Smith gives a rule for finding a numerical ratio, extremely near to any fraction of the major comma, as $\frac{q}{p}c$, viz. $\frac{161p-q}{161p+q}$; thus $\frac{1}{11}c, = \frac{161\times 11-1}{161\times 11+1} = \frac{1770}{1772} = \frac{885}{886}$, is extremely near to $\frac{1}{11}$th of a comma, being 1.0007020 Σ, and $\frac{1}{11}c$ is 1.00071476 Σ, the difference of which is not more than $\frac{1}{78279}\Sigma$ or $\frac{1}{861826}c$, which would be absolutely imperceptible in the most delicate experiments in harmonics. The major comma is $\frac{1}{55.797636}$ VIII, $=73.55193\times f$, $=1400.0913\times m$, $=5.120743\times\tau$.

COMMA *Minor* (€), is an interval, the difference between two major semitones and a major tone, whose ratio is $\frac{2025}{2048}$; the component primes of which are $\frac{3^4 5^2}{2^{11}}$: its common logarithm is .9950950,7525: its binary, or Euler's logarithm, or decimal value of the octave, is =.01629381: in those where the major comma is the unit, =.9091561; and where the schisma is the unit, =10.0078624: in the new notation of Mr Farey, it is $10\Sigma+m$: in the elements of perfect tune, it is €: in diatonic elements, 2 S—T, as before observed: in chromatic elements it is S—𝕊: and, in corcordant or tunable elements, 3 4—III—3, or 3 4—V—2 III, or 3 VIII—2 III—4 V. According to which last method, this interval is tuned (between B and c♭) on Mr Liston's organ, as shewn in the *Philosophical Magazine*, vol. xxxvii. p. 275.

The following equations exhibit the value of the *minor comma*, in terms of all the several intervals in the Table, Plate XXX. of Vol. II. viz.

This interval has been called the lesser comma by some: M. Chladni calls it a comma: it is the apotome minor of Salomon Delaus: the minor apotome of some writers: the diaschisma of Euler: the diesis major of Maxwell: the grave diesis, or grave diminished second, of Liston; and it is $=.3976837\times f$: it forms the interval between 23 of the adjacent notes in his scale. See *Philosophical Magazine*, vol xxxix, p. 373. M. Euler states it to be nearly the $\frac{1}{61}$st part of the octave.

COMMA *Maximum*, comma of Pythagoras, Boethius, &c. or ancient comma, is an interval whose ratio is $\frac{524288}{531441}$, $=12\Sigma+m$, or the DIASCHISMA (đ). This interval has also been called the comma syntonum, the comma ditonicum, and is the major comma of Kollmann.

COMMAS, *Various*. We shall now proceed to give, in a Tabular form, as in Plate XXX. vol. ii. some of the most useful particulars, of all the intervals which we have met with in musical writings, under the name of *Comma*, viz.

No.	Ratios, or Fractions.	Indices of the Primes 2	3 &	5	Common 11-place Logarithms.	New Notation. Σ	f.	m.	Binary Logarithms.	Comma Logarithms.
1	$\frac{32768}{32805}$	15	—8	—1	.9995098,9287	1.	0	0	.00162810	.09084418

No. 1. in the above Table, is a comma mentioned by M. Chladni.—No. 2. is the comma minimum of some writers, it is the semi-comma minime of Rameau, but is our Schisma (Σ), which see.—No 3. is the $\frac{1}{612}$th part of the *octave*, and is the undecomma or artificial comma of Mr Farey, in that particular case where it measures the octave; see the *Phil Mag.* vol. xxxix. p. 420, and our article Common-measures of *Intervals*.—No. 4. is a comma of Philolaus, which he states to be very near to another comma, the $\frac{1}{27}$th part of a *tone-major*, which next follows No. 5.—No. 6. is a comma mentioned by Galileo, but owing to a mistake, in the numerical operation by which he derived it, otherwise he would have obtained the comma of Pythagoras (No. 19. in this Table), as Mr Overend has shewn in his manuscripts.—No. 7. is the smaller comma of M. Chladni.—No. 8. is a comma mentioned by M. Chladni; it is the error or flattening of the false minor third on the trumpet and horn; see Chromatic *French horn*.—No. 9. is the comma of M. Chladni and the lesser comma of some writers, it is our *Minor* Comma (€), already fully described.—No. 10. is the half of the *enharmonic diesis*, which Dr Callcott has called a comma.—No. 11. is the $\frac{1}{58.25}$th part of an *octave*, and is said to be the artificial comma of Mersennus, according to Dr Holder.—No. 12. is the *Major* Comma (c), of which we have fully treated.—No. 13. is $\frac{1}{5}$th of the *major semitone*, a comma of Boethius, and one which Dr Callcott mentions.—No. 14. is $\frac{1}{4}$th of the *limma*, and is another comma of Boethius.—No. 15. is the $\frac{1}{53}$d part of the *octave*, the artificial comma of N. Mercator, in that particular case where it measures the octave.—No. 16. is $\frac{1}{9}$th part of the *major tone*, and is another comma of Boethius, D. Nichola, &c. mentioned also by Dr Callcott.—No. 17. is the $\frac{1}{8}$th part of the *minor tone*, and is mentioned as a comma by Dr Callcott.—No. 18. is $\frac{1}{4}$th part of the *semitone medius*, and is another of the commas noticed by Dr Callcott.—No. 19. is the comma of Pythagoras, Boethius, &c. the ancient comma, the comma maximum of some writers; the comma syntonum, the comma diatonicum, and the major comma of Kollmann, but is our Diaschisma (đ), see that article.—No. 20. is the $\frac{1}{3}$d part of a *minor semitone*, that is mentioned as a comma by Dr Callcott.—No. 21. is a comma mentioned by M. Chladni, and is the error or flattening of the minor seventh on the trumpet and horn; see the article above quoted.—No. 22. is the double *minor comma*, and is = 2 €, = Ɛ − Σ = ʄ − đ. No. 23. is the comma greater of some writers, and one of the commas of M. Chladni, but it is our *Enharmonic* Diesis (Ɛ), which see.—No. 24. is the double *major comma*, and is = 2 c, = Ɛ + Σ, = ʄ − χ, = đ + €, = ʃ − c, = Ꞩ − ʄ, = P − Ꞩ, = 5 T + 2 S − VIII.—No. 25. is the bearing comma of Mr Holder.—And No. 26. is the ancient comma of Galileo and one of the commas of M. Chladni, and is = 2 c + €, = Ɛ + c, 3 € + 2 Σ, = Ꞩ − π, = S − ʄ = T − 2*t* + 2 S.

Comma *and Half.* Besides the above commas and artificial commas, &c. of authors, certain intervals have been called *comma and half*, we shall insert these as a continuation of the above Table, viz.

No. 27	$\frac{1953125}{1990656}$	−13	−5	9	.9917338,2182	{17. / 16.850339}	−1 / 0	2 / 2	.0274596	1.532183
28	$\frac{625}{648}$	− 3	−4	4	.9843050,1147	32.	0	3	.0521371	2.909156

No. 27 is called the comma and half by Rameau, and is = 16.866064 × Σ, = c + R, = đ + F + 4 Σ, = € + R + Σ, = c + F + 5 Σ, = € + F + 6 Σ, = ʃ − π, = Ɛ − ʄ€, = đ + R − Σ, = 4 € + 2 Σ − ʄ, = 2 S + Ꞩ − 4 Ꞩ, = T − 4 *t* + 5 S, = 5 3 − 4 III.—No. 28. is the comma and half of Galileo, and is our Semitone *minimum* (ʃ), which see: it is a repetition of No. 26, above.

Semi Commas various. The following have been called *Semi Commas*, viz.

29	$\frac{15552}{15625}$	6	5	−6	.9979662,2157	4.	1	0	.0067561	3769725
30	$\frac{2097152}{2109375}$	21	−3	−7	.9974761,1443	5.	1	0	.0083842	.4678167
31	$\frac{590625}{593216}$	−17	−1	8	.9971288,5368	{6. / 5.850339}	−1 / 0	1 / 1	.0095377	.5321834
32	$\frac{78125}{78732}$	− 2	−9	7	.9966387,4655	{7. / 6.850339}	−1 / 0	1 / 1	.0111659	.6230275

No. 29. is the Semi-comma *major* of Rameau (ʄ€), see that article: it occurs between two of the adjacent notes on Mr Liston's enharmonic scale, viz. between F′♭ and E′✕, and between B′♭♭ and A′✕, see the *Phil. Mag.* vol. xxxix. page 419.—No. 30. is the Semi-comma *maxime* of Rameau (ʄ c), see that article: it is also called a hyperoche by Dr Busby.—No. 31. is called, in the Callcott manuscripts in the library of the Royal Institution, the semi-comma minor of Rameau (but which is inconsistent with the *major* above), and is the eschaton of M. Henfling and Mr Travers: it is our *Major* Residual (R), which see.—No. 32, is the mean semi-comma of Rameau: its schisma logarithm is 6.858202; in elements of perfect tune it is ʄ + 3 € + 2 Σ; in diatonic elements 2 T − 4 *t* + 3 S; in chromatic elements S + 2 Ꞩ − 4 Ꞩ; and in concordant or tunable elements it is 6 3 − III − 3 4, by which it might be tuned, on Liston's organ, or any similar instrument if wanted. It is equal R + Σ, = F + 6 Σ, = ʃ − ʄ, = € − χ, &c. The above list, which might probably be extended, if our reading had been still more extensive, shews how necessary it is, for authors and readers of musical works, to be on their guard, as to the numerous and variable uses of the word *comma*. For want of this attention, and using No. 12, 15, and 19 indiscriminately in part of his writings, a late author on temperament, Mr Hawkes, has drawn some very erroneous conclusions, as to his own scale of temperament, as has been shewn in the Philosophical Magazine, vol. xxxvii. p. 321, and where he is stated to adopt the intermediate comma of the three above, as the foundation of his proceedings; and yet since that period, he is said to have changed his mind, and preferred the first comma or No. 12, according to which Mr Liston has calculated the temperaments of his system at page 22 of his "Essay on perfect Intonation," viz. the third of the schemes of temperament there given. With respect to *artificial commas*, it will be necessary to say something more par-

Commelina, Commensurable Intervals.

ticular, as to the invention and use of these apparently COMMON MEASURES *of musical ratios*; for which, see that article. (*e*)

COMMELINA, a genus of plants of the class Triandria, and order Monogynia. See BOTANY, p. 96.

COMMENSURABLE INTERVALS, in Music, are such only, whose ratios in numbers, have both their terms, *the same power* of some numbers respectively; as for instance, both the numerator and denominator of the fraction, or terms of the ratio, squares, both cubes, both biquadrates, numbers, &c.: in which case, the interval is an exact multiple of some other smaller interval: thus, in the Table in Plate XXX. Vol. II., the ratios answering to 4 ℰ and to 3 *f* are the only ones, whose numerator and denominator in col. 3. are both biquadrates, cubes, squares, or any other power, of any whole number whatever. In like manner, the indices of the primes 2, 3, and 5, in col. 4, and also the numbers of Σ, *f*, and *m*, in col. 6. respectively, are prime to each other, or have no common measure but unity, in any of the lines of the Table, except those of 4 ℰ and 3 *f*, above mentioned. And the same thing will hold, in the terms of any notation by 3 intervals, in which these or other intervals may be expressed. So that except the few intervals that are thus obviously *multiples* of some others, and ought not to have separate names, but be called double, triple, quadruple, &c. of their component intervals, as No. 22. in our Table of COMMAS (see that article) is the double minor comma, No. 24 is the double major comma, &c.

All useful or practicable musical intervals, are prime, or the terms of their ratios are irrational, or surd, towards each other; and strictly speaking, such a thing as a COMMON MEASURE (see that article) among musical intervals, is impossible. This general incommensurability of musical intervals arises from the very nature of the prime numbers of which their ratios are composed; of which primes it is demonstrable, that no finite power of one prime number can exactly equal any finite power whatever of any other prime number, nor can the multiples of any two produce a third prime number. And so, no number of any interval, can exactly equal any number of another prime or incommensurable interval, as most of those in practice are: for instance, no number of 3ds, IIIds, 4ths, Vths, 6ths, VIths, &c. can exactly make up an octave, or any number of such; no number of 3ds can make any number of Vths, nor can any number of IIIds do the same thing, &c. When it is said, that two intervals, or their ratios, are incommensurable, or prime to each other, it is by no means meant that all the numbers composing such ratios are *prime numbers*; indeed, that is seldom the case. Thus, if $\frac{8}{9}$ and $\frac{25}{27}$ are compared, all the *numbers* concerned are either squares or cubes, and yet these ratios are absolutely prime to each other. (*e*)

COMMENSURABLE SYSTEMS *of musical Intervals*; are such tempered systems of 7 notes or septaves, whose intervals being T, T, L, T, T, T, and L, (where $5\ T + 2\ L = \text{VIII}$), T has a finite or commensurable ratio to L; as suppose, T : L : : 8 : 5, then such an octave consists of $5 \times 8 + 2 \times 5 = 50$ equal parts, whereof the tone $= 8$, and the limma $= 5$ parts.

So in a system of 12 notes or douzeave, *l*, L, L, *l*, L, *l*, L, *l*, L, L, *l*, and L, (where $T - L = l$, and $7\ L + 5\ l = \text{VIII}$), if L is to *l* in any finite ratio, this also is a commensurable system; if for example, L : *l* :: 5 : 3, then $7 \times 5 + 5 \times 3 = 50$ parts in the octave, as above.

The 12 intervals above, being considered as between the notes C, C※, D, E♭, E, F, F※ G G※, A, B♭ B

Commensurable Systems.

and *c*, constitute a regular douzeave; to which the notes of the octave next above, *c*※, *d*, *e*♭, *e*, *f*, *f*※, *g*, *g*※ *a*, &c. being joined, (each an exact octave above those in the given octave), then the consonances that can be taken *true*, or according to the intended system of temperament, are, as in the following Table, in part extracted from the *Philosophical Magazine*, vol. xxxix. p. 414, viz.

Consonances.	Bass and Treble Notes.	Regular Temperaments.
2	C※ D, DE♭, EF, F※ G, G※ A, AB♭, and B*c*	L
II	CD, DE, E♭F, EF※, FG, F※ G※, GA, AB, B♭ *c*, and B*c*※	L + *l*
3	CE♭, C※E, DF, EG, F※A, GB♭, G※B, A*c*, and B*d*	2 L + *l*
III	CE, DF※, E♭G, EG※, FA, GB, A*c*※, and B♭*d*	2 L + 2 *l*
4	CF, C※ F※, DG, EA, FB♭, F※B, G*c*, G※ *c*※, A*d*, B♭ *e*♭, and B*c* .	3 L + 2 *l*
IV	CF※, DG※, E♭A, FB, G*c*※, and B♭*e*	3 L + 3 *l*
V	CG, C※ G※, DA, E♭ B♭, EB, F*c*, F※ *c*※, G*d*, A*e*, B♭*f*, and B*f*※ .	4 L + 3 *l*
6	C※A, DB♭, E*c*, F※ *d*, G*e*♭, G※ *e*, A*f*, and B*g*	5 L + 3 *l*
VI	CA, DB, E♭*c*, E*c*※, F*d*, G*e*, A*f*※, B♭*g*, and B*g*※	5 L + 4 *l*
7	CB♭, C※B, D*c*, E*d*, F*e*♭, F※*e*, G*f*, G※ *f*※, A*g*, and B*a*	6 L + 4 *l*
VII	CB, D*c*※, E♭*d*, F*e*, G*f*※, A*g*※, and B♭*a*	6 L + 5 *l*

And the consonances that will result, or form *wolves*, on a douzeave instrument, for want of more than 12 strings or pipes, are as follows, viz.

Consonances.	Bass and Treble Notes.	Wolves.
2	CC※, E♭ E, FF※, GG※, and B♭ B	*l*
II	C※ E♭, and G※ B♭	2 L
3	E♭ F※, FG※, and B♭ *c*※	L + 2 *l*
III	C※ F, F※ B♭, G※ *c*, and B *e*♭ . .	3 L + *l*
4	E♭ G※	2 L + 3 *l*
IV	C※G, EB♭, F※*c*, G※*d*, A*e*♭, and B*f*	4 L + 2 *l*
V	G※ *e*♭	5 L + 2 *l*
6	CG※, E♭ B, F *c*※, and B♭ *f*※ . . .	4 L + 4 *l*
VI	C※ B♭, F※ *e*♭, and G※ *f*	6 L + 3 *l*
7	E♭ *c*※, and B♭ *g*※	5 L + 5 *l*
VII	C※ *c*, E *e*♭, F※ *f*, G※ *g*, and B *b*♭ .	7 L + 4 *l*

The above Tables, to which we shall frequently have occasion to refer, when treating on Tempered Systems, exhibits all the relations of the notes in a *regularly tempered system*, that is, wherein all the fifths, in modulating, either by flats or by sharps, from C (to G※ *e*♭, when there are but 12 notes,) are alike tempered, as far, at least, as the numbers of sounds in the octave will admit; and shews, that when L and *l* have a finite or commensurable ratio, all the intervals that can arise in the scale, being expressed in those terms, as in the last columns, are also finitely or commensurately related, in all *commensurable systems*. In the example of M. Henfling's system of 50 equal parts in the octave referred to above, since L = 5 and *l* = 3, the regularly tempered consonances 2, II, 3, III, &c. will be 5, 8, 13, 16, &c. of such equal parts; and the wolves of this system, on defective instruments, 2, II, 3, III, &c. will

Commensurable Systems.

be 3, 10, 11, 18, &c. of such parts; the two series differing 2, or the major diesis L — l, in each case; for it will be observed, that the wolf always arises, by the substitution of L for l, or *vice versa*. And all such false intervals, called wolves, differ a major diesis (d) from the regularly tempered intervals of the same name or degree.

In commensurable systems, if the octave and any one other of the 22 intervals in the Tables, or any two among them be given, it will be easy to find the values of L and l therefrom, and thence the values of all the remainder of the 23 intervals: thus, if the octave be given = 50, (of any certain intervals or parts,) and the fifth = 29 (of the same parts,) then $7L + 5l = 50$, and $4L + 3l = 29$, whence $3L + 2l = 21$, and $L + l = 8$; $L = 8 - l$, and $24 - 3l + 2l = 21$, or $3 = l$, and $5 = L$; whence every thing else in the system may readily be found. So also, if the tempered III were given = 16 parts, and the VIth wolf = 39 parts, we have $2L + 2l = 16$, or $L + l = 8$, and $6L + 3l = 39$, or $2L + l = 13$; whence will be found $L = 5$ and $l = 3$, as before.

Merely giving the number of equal parts, into which the octave of a commensurate system is divided, is insufficient to determine that system, unless it be further given or assumed, that T and L, (and consequently L and l) are *whole numbers*, as Mr Farey has shewn in the *Philosophical Magazine*, vol. xxxviii. p. 435, and has there subjoined a general rule for finding all the possible and practicable answers to such questions, which rule (for T and L) we shall not repeat here, but give a similar one adapted to L and l, which will be found more useful, in conjunction with our Tables above. In the case of the octave divided into 50 equal parts, as before mentioned, all the possible integer values of L and l are as follows: viz.

$$\begin{array}{l} \quad\ \ \mathrm{L} \qquad\quad l \\ 7 \times 0 + 5 \times 10 = 50 \\ 7 \times 5 + 5 \times \ \ 3 = 50 \end{array}$$

And wherein it is plain that only the second line is applicable to a system of intervals, and gives L = 5 and l = 3, as before found.

Our general rule is as follows: viz. From the given number of equal parts (a) in the octave, deduct successively the multiples of 7, in the series 0, 7, 14, 21, 28, 35, &c. until a remainder is found divisible by 5, or which ends in 0 or 5, as all such numbers do, and let such multiple of 7, or subtrahend, be called b; then will $\frac{a-b}{5}$ be the greatest value of l, and $\frac{b}{7}$ the least, or corresponding value of L; and all other corresponding values of l will decrease from this by 7, and those L increase by 5, as in the example above.

Since L and l both represent half notes, or tones, it is plain that they can never, in practicable systems, differ much from each other, yet they never will coincide, except in the equal temperament, or isotonic system; and it will always be easy to select that line among the possible values of L and l, which answers the intended conditions. As another example, suppose the octave divided into 612 equal parts, or artificial commas of Farey, then

$$\begin{array}{r} \mathrm{L} \qquad\quad l \qquad\quad \\ 7 \times 1 + 5 \times 121 = 612 \\ 7 \times 6 + 5 \times 114 = 612 \\ 7 \times 11 + 5 \times 107 = 612 \\ 7 \times 16 + 5 \times 100 = 612 \\ 7 \times 21 + 5 \times 93 = 612 \\ 7 \times 26 + 5 \times 86 = 612 \\ 7 \times 31 + 5 \times 79 = 612 \\ 7 \times 36 + 5 \times 72 = 612 \\ 7 \times 41 + 5 \times 65 = 612 \\ 7 \times 46 + 5 \times 58 = 612 \\ 7 \times 51 + 5 \times 51 = 612 \\ 7 \times 56 + 5 \times 44 = 612 \\ \text{\&c.} \qquad\qquad \text{\&c.} \qquad \end{array}$$

shew the possible values of L and l: the last line but one shewing that 51 might answer for both L and l, each of which are, in such cases, the 12th part of the octave, for the isotonic or equal temperament system. The last line gives L = 56 and l = 44, which are in the ratio of 14 and 11, and answer also to 153 parts in the octave, &c. (ę)

COMMERCE.

Commerce.

COMMERCE is frequently used in the limited sense of "mercantile intercourse with a foreign country," while *trade* is made to denote "traffic among the inhabitants of the same country." Strictly speaking, however, there is no foundation for this distinction, either word being entitled, both by etymology and decisive authority, to a comprehensive and general interpretation. Either may therefore be defined, in the broadest sense, "an exchange of commodities, whether the object of the exchange be consumption or re-sale at a profit." We shall divide our discussion of this subject into three heads.

1. Historical sketch of commerce.
2. Present state of British commerce.
3. Observations on the principles of commerce.

History of Commerce.

I. *Historical sketch of commerce.*—The origin of commerce is involved in the same obscurity as the other occupations of an early stage of society. Its beginnings, like those of other things, must have been extremely rude, and must have consisted in nothing more than a barter of one simple article for another. In progress of time, certain articles of general utility, and which were capable of transportation, such as brass, iron, cattle, &c. became a kind of standard for the purchase of other commodities. Such appears to have been the case at the time of the Trojan war, and likewise, probably at the later period, when Homer composed his poem. A farther improvement in the mode of managing commerce, consisted in the adoption of gold and silver as money, or general representatives of value. This important point once established, it was easy to make the additional progress of stamping on the metal an official mark declaratory of its weight; and eventually, to constitute the mark, in the shape of coin, an indication of its fineness as well as of its weight. An attention to the different stages in the progress of currency, affords the inquirer a good criterion of the advance of commerce. In maritime countries a similar rule is offered by the progress of navigation. The conveyance of merchandize by water is, after mankind emerge from primitive ignorance, so much easier than by land, that we may safe-

Commerce.

ly take for granted, that the people who possess opportunities of this description, without turning them to account, are very little advanced on the road to civilization.

Commerce of the Egyptians, &c.

In looking to historical documents for the first indications of commerce, the plan is to direct our attention to the earliest records of established society. These, as is well known, exist in the case of Assyria, Judæa, Egypt, and the surrounding countries. Here, accordingly, we find the descendants of Ishmael, "coming from Gilead, bearing spices, balm, and myrrh, going to carry it down to Egypt." In these days, merchants superintended the carriage of their own commodities, the expedient of transferring that duty to others, an arrangement so simple in our eyes, being incompatible with the rude customs of an unsettled people, and the difficulty of traversing an almost desert country. In Egypt, the progress of population, and consequently of commerce, appears to have been rapid, but not to have led to a correspondent improvement in navigation. However the national aversion to the sea being partially overcome, the Egyptians shared with the Phœnicians the honour of colonizing the far-famed shores of Greece.

Commerce of the Phœnicians.

The Phœnicians seem to have been early induced, by the convenience of their harbours, and the vicinity of timber, to make navigation a regular employment. It is common to ascribe their application to this pursuit, to the ungrateful nature of their soil; a consideration, which will not be received by those who examine with attention the causes of national progress. When other circumstances are equal, the fertile country is as likely to take the lead of a barren one in navigation, as in other departments of industry. Its soil supplies a larger stock of exchangeable commodities, and its superior density of population, accelerates the acquisition of those various branches of knowledge, on which the adventurous and complicated art of navigation depends.

The Phœnicians are understood to have surpassed all their neighbours in the eastern part of the Mediterranean in extent of commerce. Their reputation rests on a concurrence of traditional and historical authority, and the power of their capital Tyre, was ascertained beyond a doubt, by the length of her resistance to the overwhelming forces of Alexander. Superior, however, as the Phœnicians were to their immediate neighbours, they were probably inferior as navigators to the Athenians, and evidently much behind their reputed descendants the Carthaginians.

Commerce of the Carthaginians.

Our ignorance of the early condition of the latter, is one of the principal desiderata of ancient history. Their power appears to have increased with all the rapidity attendant on confirmed habits of national industry. Notwithstanding a very defective government, and a comparative unacquaintance with land tactics, they long repressed the rising greatness of Rome; and the eventual triumph of the latter may be ascribed, according to the judicious remark of a late writer,* to that fortunate constitution, which gave every citizen an interest in the prosperity of the republic. The navigation of the Carthaginians embraced the north of Africa, Sicily, Spain, and, more or less, the distant shores of the Mediterranean to the east, and of the ocean to the west. How far the north of France or our own coasts came, as has been long asserted, within the range of their exploring labours, we will not pretend to determine.

Commerce of the Greeks.

In Greece, the chief commercial cities were Athens and Corinth. Each sent abroad colonies, which rivalled the trade and navigation of the parent state. The Euxine on the one hand, and Sicily on the other, appear to have been almost the farthest limits of Grecian commerce; but an active traffic must, no doubt, have been carried on with the nearer shores of Thrace, Asia Minor, and Italy. The superiority of the Greeks over the Persians in actions by sea as well as by land, rests on undoubted testimony; but the cause of this, if analyzed, will be found to have lain more in courage than in dexterity. The Greeks generally fought in small vessels without decks, and rushed forward with impetuous valour to board the ships of their enemies. (*Thucydides*, l. 1. c. 14.) So little were they advanced in navigation, that, at the time of the expedition of Xerxes, the distance between Ægina and Samos was made an objection to their attempting the voyage. (*Herodotus*, lib. 8. cap. 132.) Their knowledge of the rest of the globe was founded on conjecture, or derived from the verbal reports of the few persons, who had been induced, by love of science, or by commercial pursuits, to extend their travels into Asia Minor, and into Egypt. The obstinate defence of Tyre seems to have given Alexander a powerful impression of the vast wealth derived from commerce, especially from that with the East Indies. He was accordingly induced, after conquering Egypt, to lay the foundation of a city, which was to be the centre of trade as well as the seat of dominion. The situation of Alexandria was so well chosen, that it continued a great commercial sea-port for many ages, and did not fall into absolute decay until the loss of the India trade, by the discovery of the passage by the Cape of Good Hope.

Commerce of the Romans.

The progress of the Romans in navigation and discovery was still less considerable than that of the Greeks. Their military education, and the spirit of their laws, concurred to estrange them from commerce and naval affairs. It was the necessity of opposing a formidable rival, not the desire of extending trade, that first prompted them to aim at maritime power. Its advantages soon became apparent, though, after they had rendered themselves masters of the sea, they still considered the naval service in a subordinate light, and never imbibed the commercial spirit of the conquered nations. Trade and navigation were abandoned, like the mechanical arts, to slaves, to freedmen, to provincials, and to citizens of the lowest class. Yet the spirit of the Roman government, and the consolidation of rival states into one empire, had the effect of giving great additional security to commerce. By sailing to the Indian continent from the Red Sea, navigators became acquainted with the periodical course of the winds. (*Plin. Hist. Nat.* lib. 6, c. 23.) The uniform direction of the breeze supplying the place of the compass, and rendering the guidance of the stars less necessary, they reached the western shore of the Indian continent with safety, and with equal facility returned with the eastern monsoon. The discovery of this new method of sailing to India, was the most considerable improvement in navigation made during the continuance of the Roman power; for, in ancient times, the knowledge of foreign countries was acquired much more by land than by sea.

The transfer, in the fourth century, of the seat of empire to Constantinople, could not fail to affect the wealth and grandeur of Rome. The subsequent invasion of barbarous hordes tended farther to divest mercantile intercourse of the requisite security; and in the

* Mr Brodie, author of the *History of the Roman Government.*

Commerce. course of ages, Constantinople appeared to be almost the only place where commerce flourished, and the literary treasures of antiquity were to be found. No situation could be better adapted to the maintenance of communication with surrounding countries. On the one hand lay the Euxine; on the other, the Mediterranean. When Egypt was separated from the empire by the Arabians, and the intercourse with India was suspended, a new channel was found out for the transport of eastern commodities. They were carried up the Indus, as far as that great river is navigable, and were then transported by land to the banks of the Oxus. Here they were again put on ship-board, and conveyed down the stream to the Caspian, where they served to load vessels belonging to the merchants of Constantinople. *Ramusio*, vol. 1. p. 372.

Progress of commerce in Italy.

In modern times, Italy became, from the concurrence of different causes, the chief scene of the revival of commerce. Venice was founded in the midst of waters, by fugitives, who sought safety in flight from the ravages of the Huns. In progress of time, this little republic became the seat of wealth and of considerable political power. The possession of the trade to India, by way of Egypt, has been accounted by many the main spring of that grandeur, of which the origin should be sought in a more comprehensive cause. Genoa and Pisa followed in the same career of industry and prosperity; but their progress was eventually retarded by wars abroad, and by civil dissensions at home. Constantinople, being still the only great city in that age, became the principal mart of the Italians. There they obtained great mercantile privileges, and were supplied both with the precious commodities of the East, and those which the ingenuity that still subsisted among the Greeks enabled them to manufacture, and vend to their neighbours. The sagacity of the Italians discovered also other methods of procuring rare and precious commodities, as they were enabled to purchase them occasionally in Aleppo, Tripoli, and other parts of Syria, to which they were brought by a route not unknown to the ancients. They were conveyed from India by sea up the Persian Gulf, and, ascending the Euphrates and Tigris as far as Bagdad, were carried by land across the desert to Palmyra, and from thence to the towns on the Mediterranean. It was while Italy was thus advancing in the career of improvement, that the martial spirit of the Europeans, inflamed by religious zeal, prompted them to attempt to deliver the Holy Land from the dominion of the Infidels. A new sphere for Italian industry was here created. The Genoese, the Pisans, and Venetians, supplied the crusaders with military stores, provisions, and shipping; receiving in return large sums of money, as well as great commercial privileges in Palestine and the maritime parts of Europe. The sight of the comparatively civilized countries of the Mediterranean, afforded considerable means of improvement to the rude inhabitants of the north. Among other things, it deserves to be mentioned, that they here found, in the laws of Rhodes, the first outline of marine insurance. (Schomberg's *Observations on the Rhodian Laws.*) By a fortunate coincidence, the discovery of the mariner's compass took place soon after. This discovery, which has been truly said to have "opened to man the dominion of the sea," was made by a citizen of Amalfi in Italy, about the year 1302. It was in vain that the commercial jealousy of the Italians laboured to conceal it from other nations. Its properties were of too general use to be kept secret.

Our countrymen appear to have been considerable gainers, as well as their neighbours, by the intercourse with the civilized part of Europe attendant on the crusades. Our enterprising monarch, Richard I. is supposed to have directed the compilation of the celebrated laws of Oleron (Selden *de Dominio Maris*, c. 24.) from the Rhodian maritime code. However, the progress of English commerce was not in correspondence with so auspicious a beginning; for in the reign of Edward III. more than a century afterwards, navigation (Hume's *History of England*, 8vo. edit. vol. ii. p. 494.) and industry were at a low ebb. That monarch, struck with the flourishing state of Flanders, and perceiving the true cause of its prosperity, endeavoured to excite a similar spirit among his subjects, who seemed blind to the advantages of their situation, and unacquainted with the sources, whence they (Robertson's *View of Society*, &c.) might derive wealth and opulence. So far were they lulled by ignorance and indolence, that they did not even attempt those manufactures, the materials of which they themselves supplied to foreigners. But notwithstanding the endeavours of Edward, and the many wise establishments proposed and encouraged by him, (Park's *Introd.* 36. 5th edit.) it was not till the reign of Elizabeth, that the English began to discover their true interests, and the arts by which they were to obtain the pre-eminence which they now hold among commercial nations. This slow progress may be accounted for on various grounds. During the Saxon heptarchy, England was split into many kingdoms, perpetually at variance with each other. It was exposed to the incursions of the northern pirates, sunk in barbarity and ignorance, and consequently in no condition to cultivate commerce, or pursue any system of wise and useful policy. To this succeeded the Norman conquest, and all the consequences of a feudal government, military in its nature, hostile to commerce, to the arts, and to the refinement of a liberal and civilized people. Scarcely had the nation recovered from the shock occasioned by this revolution, when it was engaged in supporting the pretensions of its monarchs to the French crown; and it long continued to waste its vigour and wealth in wild endeavours to conquer that country. To this we may add the destructive civil wars between the houses of York and Lancaster, which deluged the kingdom with blood, and to which a period was at last happily put by the union of their several titles to the crown, in the person of Henry VII. The reformation became the next source of agitation, and it was not till the reign of Elizabeth, that the feuds and dissensions, which such an important event necessarily occasioned, began to subside. During her long reign, and her wise administration, commerce began to rear its head, and found at last effectual protection from the directors of public affairs.

Progress of commerce in England.

Hanseatic league.

On turning from our own country to the continent of Europe, our attention is chiefly occupied by the celebrated Hanseatic league. This league took its origin from the necessity of a permanent confederation on the part of the different cities, for the purpose of protecting their navigation. Europe in that age was occupied by men "whose trade was war," and who accounted it no great crime to lay violent hands on the property of a foreign merchant. In the year 1200, this association had branched out so as to comprehend no less than seventy-two cities, consisting of sea-ports of the Baltic, Holland, France, Spain, Portugal, England, and a few of the Italian ports. Such was the progress of a union, confined on its first formation to the towns of Lubeck, Bremen, and Amsterdam. The league lasted in power and splendour to the sixteenth century, a period during

Commerce. History of English commerce.

which it had occasion, more than once, to resort to arms, and punish the rapacious disposition of the kings of Denmark. At last the improved government of Europe, lessening the necessity of this confederation, the different branches of the league gradually fell off, and remained satisfied with the protection of their respective sovereigns.

In the fourteenth century, the woollen manufacture was so little understood in this country, that Edward III. wrote a letter with his own hand, to John Kemp, a woollen manufacturer in Flanders, offering to take him, and his servants, apprentices, goods, and chattels, under his royal protection, (Rymer's *Fœdera*, p. 496.) and promising the same to all others of his occupation, as well as to all dyers and fullers, who should incline to come and settle in England. (A. D. 1337.) No less than seventy Walloon families, engaged in the woollen manufacture, availed themselves of this encouraging offer, and came over to settle here. Only four years after the introduction of the first woollen manufacturers from Flanders, an act of parliament (the 11th of Edw. III. c. 2.) was passed, to prevent the exportation of wool, and holding forth protection and rewards to all cloth-workers who should come from foreign parts. By another act, (the 11th of Edw. III. c. 1.) all persons other than the king, queen, and royal family, were prohibited from wearing any cloth that was not manufactured within the realm. The importation of foreign cloth was also forbidden on pain of forfeiture and other punishment. But so jealous were the weavers of our own coarse cloths, of the introduction of better workmen from abroad, that, in 1344, a mob in London, principally composed of, and instigated by them, insulted and maltreated the foreign weavers, so that they could not carry on their business with security. Upon this warrants were issued by the king, directed to the mayor and sheriffs, to imprison the ringleaders in the jail of Newgate.

Such was the comparative insignificance of our exports, even so late as 1534, that the whole, from every part of England, did not exceed L.900,000, of the present value of our money. Yet the balance of trade in our favour at that period, was imagined to exceed L.700,000, as appears by a record in the exchequer. This balance, arising principally from the exportation of wool and woolfels, lead, tin, and leather, appeared very great in proportion to the whole amount of the trade, and produced a duty of customs on export to the amount of L.246,000, according to the present value of money, while the duty on imports amounted to little more than L.1700.* It is curious to observe by what slow degrees the commercial improvements, at present most familiar to us, were introduced among our ancestors. The practice of making remittances by bills of exchange, was so little known or followed in England in the 15th century, that Henry IV. granted leave to Philip d'Albertis, a rich Lombard merchant then residing in London, to give a bill of exchange (*literam cambii*) on his partners abroad for 2500 merks sterling to the Bishop of Bath and Wells, or his attornies, on the express condition, that "neither the said gold received for the bill of exchange, nor any other gold or silver, either in coin or bullion, be transported beyond sea under colour of that licence, upon pain of forfeiting all the money so transported."

Elizabeth fortunately possessed in Cecil a minister capable of giving unwearied attention to political subjects, and much more disposed to seek the establishment of public wealth in internal regulation than in schemes of foreign conquest. One of the earliest applications of his talents related to the copartnership of German factors of the Steel-yard, who, by a mistaken policy, enjoyed particular privileges and immunities in exporting our cloths. These factors traded principally to Antwerp and Hamburgh, and found means, partly by superior capital, partly by the enjoyment of preferences from government, to render all competition unavailing. A particular investigation being made by Cecil, it appeared that while the whole body of English merchants had exported in the preceding year only eleven hundred cloths, the German merchants of the Steel-yard had exported forty-four thousand. Their immunities were therefore abolished; and such were the effects of this decisive step, that the very next year the English merchants exported forty thousand cloths to Flanders. Of the favourable effects of this and other wise measures of Elizabeth's cabinet, we shall be fully satisfied by adverting to the circumstance of the customs having been farmed at the commencement of her reign by Sir Thomas Smith, at fourteen thousand pounds a-year, while towards its close, he paid fifty thousand pounds for them. The laws and regulations of this reign infused a spirit of enterprise into the nation, which produced wonderful effects. The passage to Archangel was discovered, and a trade opened with Russia, a region till then scarcely known in this kingdom. The Czar, John Bazilowitz, granted extraordinary privileges to the English throughout his dominions; and an attempt was made to open a trade with India by the rivers Dwina, Wolga, and the Caspian Sea, which, although tedious and expensive, would have had its advantages, had not our navigators preferred following the route of the Portuguese round the Cape of Good Hope.

The rich prizes captured by Sir Walter Raleigh near the Azores in 1593, tended farther to excite the national impatience for a direct trade with India. Accordingly, in the year 1600, a foundation was laid for this celebrated company, by associating a body of merchants, whose capital, divided into shares of £50 each, amounted in all to no more than £72,000. Their shipping likewise formed a curious contrast to its subsequent extent, being confined to five vessels, measuring only 1330 tons in all, and valued collectively at £27,000.

The judicious system pursued by Elizabeth for the advancement of trade, was considerably favoured by

* From the 11th of Edward III. to the 43d of Elizabeth, the following acts passed for improving and regulating the woollen manufactures of England, admeasurement of cloths, &c. viz.

Commerce.

the emigrations of Protestant Flemings, who fled from the tyranny of the Duke of Alva. Flanders had by that time made great progress in commerce and manufactures. Bruges, Ghent, and Antwerp, were cities superior to any in Europe, except the commercial capitals. The inhabitants were formed to the practice of regular industry, and brought over to England habits and knowledge of the most useful kind. This conduct on the part of the Spaniards was very similar, both in its motive and in its consequences, to the recal, a century afterwards, of the edict of Nantes by Louis XIV.

Origin of the navigation laws.

However questionable may be the merits of our navigation laws, with reference to our progress in commerce, it may be proper, in this article, to say a few words about their origin. It is generally assigned to the time of the commonwealth and Charles II.; but it goes, in fact, much farther back than either Cromwell or Charles, (12 Car. II. c. 18, 27 Geo. III. c. 19, 37 Geo. III. c. 63,) the first provision of this nature having been made in the latter part of the reign of Edward III. (42 Ed. III. c. 8, 7 & 8 Will. III. c. 22, 34 Geo. III. c. 42, 68.) The next law of importance on this subject, was framed in the reign of Henry VIII.; (23 Hen. VIII. c. 7, 26 Geo. III. c. 60, 35 Geo. III. c. 58.) but a law of Elizabeth's reign in 1563, entitled, "An act touching politic constitutions for the maintenance of the navy, &c." (5 Eliz. c. 5,) may be considered as in a manner the outline of the system. By this law, herrings and other fish caught on our coasts, are permitted to be exported duty free; no foreign ships are to be allowed to carry goods coastwise, from one port to another; and wines and wood were permitted to be imported from France in English ships only.

History of Dutch commerce.

Of the commercial countries on the continent of Europe, the most interesting, whether we look at its long struggle for independence, its indefatigable perseverance, or its splendid acquisition of wealth and power, is Holland. The observations of Sir William Temple, afford striking illustrations of the national character, as well as of the condition of trade, at a time when it was in full vigour. Without entering into a lengthened exposition of the history of Dutch commerce, we shall take notice of two points not generally admitted into the notions formed of this remarkable people. First, that their commerce was not of such sudden growth as is commonly imagined, Amsterdam having been a large and populous city before the revolt from the Spanish yoke; and secondly, that until the present age of unexampled distress, the navigation and wealth of the Dutch had not undergone that great decrease which many writers have put upon record. Their fall had been more relative than absolute; the other maritime states of Europe, particularly England, having advanced during the last century with great rapidity. The Dutch continued industrious, economical, and even enterprising; but their own territory being small, and of little fertility, a great proportion of their capital was lent out on foreign securities. Not only were the treasuries of princes replenished by loans from Holland, but a variety of private undertakings, such for example as iron mines in Sweden, were worked by Dutch capital. Their wealth was thus made instrumental in augmenting the prosperity of other countries, and afforded a memorable indication of the laws by which the indefinite acquisition of property is restrained. Besides, the debts of other countries to Holland being payable not in real property but in money, underwent that progressive and eventually great depreciation, which has marked the history of the circulating medium throughout Europe. We now return to the affairs of our own country, and proceed to examine the present state of British commerce.

Present state of British commerce.

II. *Present State of British Commerce.*—On looking back to the æra of the Restoration, we find, that the whole quantity of merchant shipping employed in our coasting and foreign trade did not exceed 140,000 tons. Of these, the third part was foreign, and particularly Dutch, which led Sir William Temple to remark, that, notwithstanding our discouraging foreign vessels in our ports, the trade between England and the Continent was principally conducted by Dutch vessels. In spite of the bad government of Charles II. the enjoyment peace during the chief part of his reign, produced great increase in our mercantile shipping, so that, at the Revolution, it was found to have doubled in the course of the preceding twenty-five years. The long wars under William and Anne operated to retard its augmentation; but the peace of Utrecht gave fresh vigour to our trade, and enabled us to dispense with those neutrals to whom we had had recourse in the season of hostility. However, the increase of our trade during the first half of last century was very gradual. In the long period of almost uninterrupted peace between 1713 and 1739, our tonnage did not increase above one-seventh, viz. from 421,000 to 476,000 tons. The value of our exports was less stationary, and rose somewhat more than a fourth, viz. from £7,300,000 to £10,000,000. In the interval of peace between 1748 and 1755, a considerable improvement took place. The recommencement of war damped it to a certain degree; but on the whole, the increase during the latter half of last century was very great, as we perceive from the subjoined Table.

	The first year of Geo. III.	Tonnage of Merchant Vessels cleared outwards. English.	Tonnage of Merchant Vessels cleared outwards. Foreign.	Value of our Exports.	Nett amount of our Customs.

Commerce.

Having thus seen the history of the progressive augmentation of our exports, we are next to observe the proportions in which they are distributed to different countries.

Custom-house Return of the Official Value of the Exports from Great Britain to the Continent of Europe, to the West Indies, to America, to Africa, and to Asia, respectively, from 1805 *to* 1809, *inclusive.*

	1805.	1806.	1807.	1808.	1809.
Continent of Europe . .	£15,465,430	£13,216,386	£12,689,590	£11 280,490	£23,722,615
West India Islands . . .	4,096,196	5,339,612	5,433,267	7,507,575	8 755 193
Continent of America . .	8,067,671	10,754,140	9,455 028	8 369,472	10,570,100
Africa	990,625	1,433,153	797,741	532,842	703,180
Asia	1,669 214	1,936,954	1,884,438	1,933,225	1,647,927

In both Tables, the value inserted is not the real, but the official value; that is, a valuation of merchandise at a given sum per bale, trunk, cask, or other package, according to a scale laid down for the regulation of the custom-house officers above a century ago. Since the imposition of convoy duty, which is a tax *ad valorem*, the commissioners of the customs are in possession, by the declarations of the merchants, of the real value of exported goods, and find it in general about 60 per cent. above the official computation. Still the old form is retained, and is useful as exhibiting a correct statement of the progressive increase, *in quantity*, of our exported merchandise. The following extract, from a custom-house report, exhibits a contrast between the two modes of valuation, in the case of an important branch of our commerce.

Official and Real Value of the Exports from Great Britain to the Continent of Europe, from 1805 *to* 1809, *inclusive.*

	Official Value.	Real Value.
1805	£15,465,430	£20,435 940
1806	13 216 386	17,547,243
1807	12 689,590	15,420,514
1808	11,280 490	13 983,123
1809	23,722,615	27,190,337

Official and Real Value of the Imports into Great Britain from the Continent of Europe, from 1805 *to* 1809, *inclusive.*

	Official Value.	Real Value.
1805	£10,008,649	£21,744,762
1806	8,197,256	17,855,524
1807	7,973,510	17,442,755
1808	4,210,671	8,905,099
1809	9,551,857	19,821,601

The discrepancy between the two modes of valuing, is evidently much smaller in the case of continental exports than imports; a discrepancy which is chiefly to be attributed to inequalities in the alteration of the value of particular articles since the formation of the Customhouse Table. It is more particularly owing to the circumstance, that coffee, which is now very frequently exported at L. 5 per hundred weight, is valued in the Table in question so high as L. 14, the culture of that plant being at that time very little understood.

Balance of trade.

We are next to direct our attention to the question of the balance of trade;—a point on which, until lately, our merchants and ministers were accustomed to lay great stress. It is still a current notion, that the profit attendant on foreign trade is realized in the shape of a clear balance of payments made to us by the rest of the world. The customhouse books have been re-

Commerce. peatedly ransacked, for the purpose of ascertaining the particular amount of this gratifying receipt. Comparisons have been made, year after year, between our exports and imports; and the almost uniform excess of the latter has been a source of wonderful comfort to the advocates of what is called, in political economy, the mercantile system. Take, for example, the following abstract of the

Official Value of our Imports and Exports with the Continent of Europe, from 1805 *to* 1809 *inclusive.*

Years.	Imports.	Exports.	Balance in favour of Great Britain, reckoned in Official value.
1805	L.10,008,649	L.15,465,430	L.5,456,781
1806	8,197,256	13,216,386	5,019,130
1807	7,973,510	12,689,590	4,766,080
1808	4,210,671	11,280,490	7,069,819
1809	9,551,857	23,722,615	14,170,758

In this, however, are omitted some very important items, such, for example, as draughts and remittances of bills of exchange, the sum of which is frequently so very great, as to give almost a new aspect to the account. Moreover, the abstract takes no notice of the export or import of bullion; of the monies paid to foreigners for freight; nor of the value of smuggled goods. The following calculation is made out on a comprehensive plan, and exhibits an allowance for several of those considerations, which, from the nature of the customhouse books, cannot be entered in a regular shape in an official return.

Customhouse Return of the Balance of Trade in favour of or against Great Britain, in her Commerce with all Parts of the World, from 1805 *to* 1809, *inclusive.*

	1805.	1806.	1807.	1808.	1809.

	Medium of 1805 and 1806, *L.* 8,525,080.			Medium of 1806 and 1807, *L.* 9,174,118.	

Notwithstanding the attention with which this estimate was prepared by Mr Irving, inspector-general of the customs, it is necessarily defective in the points mentioned above. Whenever there exists an extraordinary difference, as in the case of our exports and imports with the continent of Europe, we have reason to suspect the existence of some latent drain; and when the great expence of our foreign garrisons and occasional subsidies is taken into account, we need be at no loss to explain the cause of the above mentioned inequality. It is singular enough, that every nation makes the balance of trade in its own favour. But the true way of estimating the difference of value between the same goods in different places, is to attend to their approximation to a market of consumption. A hogshead of sugar, for example, is of more value in Britain than

Commerce.

in Jamaica;—a ton of copper of more value in Holland than in Cornwall. By making due allowances in this respect, we shall be enabled to account for the apparent contradictions of customhouse returns, without the ridiculous supposition of a loss on one part, whenever there exists a gain on another.

Trade of Ireland.

We conclude our mercantile Tables by a statement of the trade of Ireland.

Value of all Imports into, and all Exports from Ireland, for five Years, ending the 5th January 1810*; distinguishing each Year, and the Value of Irish Produce and Manufactures from the Value of Foreign Articles exported; together with the Difference between the Official Value and the declared Value of Irish Produce and Manufactures exported in the Years ending 5th January* 1808, 1809, *and* 1810.

		Official Value of Imports.	Official Value of	
			Irish Products and Manufactures Exported.	Foreign and Colonial Merchandise Exported.
		£	£	£
Year ending 5th Jan.	1086	5,736,214	5,059,867	142,481
	1807	5,605,964	5,030,722	157,443
	1808	6,637,907	5,307,806	150,370
	1809	7,129,507	5,696,897	235,694
	1810	7,471,417	5,408,910	330,933

Note.—The real value of Irish produce and manufactures, computed at the average prices current, exported in the years ending 5th January 1808, 1809, and 1810.

Year ending 5th January	1808 . . .	£10,110,385
	1809 . . .	12,577,517
	1810 . . .	11,464,265

Principles of commerce.

III. *Principles of Commerce.*—This department of the subject will be treated at some length under the head of Political Economy. At present we confine ourselves to a few general observations, with the view rather of correcting prevalent errors, than of attempting to give any thing like a system in the case of a subject which requires so great a variety of combinations.

Our readers have seen, from the Tables above, the rapid increase in the value of our exports and customhouse duties. A similar increase has taken place, as is well known, in the value of landed property and of houses, in the general revenue of the country, &c. Although more striking, and perhaps more rapid in the present than in any former age, a progress of this nature has been regularly taking place during the last three centuries. Dr Davenant computed, that between the years 1600 and 1688, the "rental of England was nearly tripled, the money in circulation quadrupled, and the capital of the country increased fivefold."—Such augmentations are commonly, we may say almost universally, considered in the light of proportional additions to the stock of public wealth. Our ministers are accustomed to expatiate in parliament on the rapid increase of national property, as demonstrated by the increased produce of our taxes; and persons in private life, though conscious that their individual circumstances are not improving, take for granted, from the general enhancement of commodities, that there must be a large accumulation of property throughout the country. It seldom occurs to these persons, that the *fall in the value of money* would afford, in a great degree, a solution of the contradiction between their own straitened circumstances and the appearance of general prosperity. On turning to the official tables of custom duties, we find an increase of double the amount between 1792 and 1808. Part of this increase arises from additional imports; part from extension of trade. But in neither case must we flatter ourselves, that government have doubled the *real* amount of the customs, since, from the fall in money in the course of these sixteen years, eight millions in 1808, would go no farther than five or six millions in 1792. On applying a similar rule to the computation of private property, we find estates yielding now a rental of fifteen thousand pounds a-year, which, twenty years ago, did not yield nine thousand. Part of this difference is the result of the improvement of the land, but another part, by much the larger, arises from the fall of money. The proprietor, on comparing the relative prices of the necessaries and comforts of life, will find that the larger sum does not at present go much farther than the smaller did in 1793. It is not enough to contend, in opposition to this, that the rise in price has not been equal in all articles; for, in a general view of those things which constitute domestic expenditure, and for which, of course, money is chiefly required, the computation will not prove exaggerated. The great exception is found in the case of manufactures. Here the improvements, from the use of machinery and the division of labour, have been so extensive and so rapid, as to outweigh both the increase of wages and the enhancement of the raw commodity.

Commerce. Principles of commerce.

This explanation of our supposed increase of wealth is by no means flattering to those whose minds have been elated with the belief of a rapid augmentation of our power and riches. They will find, however, a kind of counterpoise to their disappointment in the exposition which we are now going to make of another popular error. It was a saying of the respected Judge Hale, that "the more populous we are, the poorer we are;" and a writer of the present day has circulated a long list of gloomy anticipations, from an apprehension of excess in population. Now the fact is, that in every tranquil and well-governed country, the ratio of increase in population may, in various respects, be regarded as an index of the advancement of its political power. We view it in this light, less as a supply for armies and navies, than as a means of augmenting the productive powers of national capital. How wide a field is still open for agricultural improvement, will be apparent on considering, that the counties which have been rendered the most productive in our island, we mean the north of England, and the south-east of Scotland, are by no means the quarters most favoured in point of soil and climate. Were the practice of granting leases general in the south and west of England, the farmers would progressively acquire the enlightened habits of their northern countrymen, and would learn, like them, to lay out capital on land with a liberal hand, in the same way that a trader lays it out in merchandise. It is superfluous to add, how greatly the produce of the earth, or, in other words, the means of supporting a growing population, would be augmented by the adoption of this simple course. Much more, we believe, would be gained by improving the management of land already cultivated, than by attempting, at a large expence, to render commons and waste lands productive. Both, however, are pleasant objects in prospect, and are of a nature to tranquillize us in regard to apprehensions of deficient provision. By the official returns of population, we have seen an increase, between 1801 and 1811, of nearly a million and a half in Great Britain; an increase owing to the introduction of vaccination, and to causes more likely to operate in peace than in war. Peace, however, in accelerating the progress of our numbers, will restore to us the labour of a portion of our countrymen, who are well calculated to extend the produce of the earth. Ireland likewise, largely as she has of late contributed to our corn supplies, is still far from being cultivated to the point of which her fertile soil is capable.

The topic which we take up, in the *third* place, is the supposed superiority of our foreign to our inland trade. It is a very common notion, that money can be made by a country by foreign trade only, while all inland transactions are mere transfers from hand to hand. If we examine the speeches of our statesmen, we find the amount of our exports perpetually adduced as the grand criterion of national wealth; and, if we look to a less friendly quarter, the cabinet of Bonaparte, we see decree follow decree on the presumption that the exclusion of British commerce from the continent would prove the grand instrument of our downfall. Nay one writer, of official eminence at Paris, M. de Montgaillard, goes the length of asserting, that "India is the grand source of the wealth of Britain; Calcutta, not London, her real capital." Notwithstanding these high-sounding authorities, we may, we believe, assert without exaggeration, that the produce of our foreign trade is not more than *one eighth*, perhaps not *one tenth* of that of the inland. We take, of course, the word trade in its most comprehensive meaning, viz. as expressive of "all industry directed to a productive purpose." We understand by it, the exertions of all those who, whether agriculturists, manufacturers, mechanics, shopkeepers, &c. labour for the progressive augmentation of their individual property. It is by thus labouring for themselves that they contribute to the extension of national wealth. The distinctions so frequently made between those who, by their business, bring money into a country, and those who are supported by professions which apparently form a charge on their neighbours, will often prove to have little foundation. The exact limit between productive and unproductive industry has not been successfully defined by our ablest political economists; but all who have gone thoroughly into the science are satisfied, that the productive character belongs as strongly to home as to foreign transactions. The practical result of this most important truth is, that the relative value of foreign commerce has hitherto been much overrated. We have gone to war with Holland and with France for particular branches of trade, and have expended, in a single twelvemonth, more of the national treasure, than would be repaid by the possession of the traffic in question for one hundred years. Another conclusion of a more consolatory nature regards the solidity of the basis on which our national power rests. France, in excluding us from the Continent, could not, with all her efforts, suspend above one twentieth part of our productive industry; a proportion by no means insignificant, but infinitely below that which both we and our enemies were led to anticipate. Accordingly, it was not until the additional loss of our North American trade in 1808, or more properly in 1811, that a serious blow was given to our commercial prosperity.

The *fourth* and *last* point to which we shall at present advert, regards an idea which is still very prevalent among people at large, although excluded from the creed of enlightened inquirers. We have in view the notion, that, in trade, one nation loses as another gains; and that rivalship in commerce is founded on serious and substantial reasons. How often has it been predicted, that the French, by the cheapness of labour, by the attention of their government, at particular intervals, to the promotion of commerce, or, by the acquisition of certain settlements, such as Louisiana or St Domingo, were about to give a death blow to correspondent branches of British manufacture and commerce. Yet ages, we may almost say centuries, have passed away, without the realization of these gloomy predictions. In regard to government interferences, we may, once for all, dismiss apprehension from our thoughts, by the conviction, that, whenever a government diverts the current of industry from its natural channel, it infallibly throws a proportion of it to waste. The only sound policy in a government is to give security to property, and freedom, unrestricted freedom, to the developement of industry. Next, as to the augmentation of public wealth consequent on this judicious course, the nations trading with a flourishing country may be assured, that their gains, from intercourse with her, will not fail to go hand in hand with her prosperity. Portugal has long been reputed the country on the Continent, from which, in proportion to its population, we obtained the largest profits; but, on close inquiry, it will be found, that we realized much more by our trade with Holland. The inhabitants of a rich country have many more wants, and can much better afford to gratify them. The security, in point of payment, is infinitely better,—a point which, though it frequently escapes the attention of a mercantile beginner, or a theoretical calculator, is, in the eye of the experienced trader, a matter of the greatest consequence. It follows, that countries of improved habits, of established capital, and of comparatively little distance, are much more profitable in the way of trade, than the dazzling and remote regions of the east or west. Distance implies a correspondent slowness in the return of capital; a disadvantage which can be compensated only by a larger increase in the rate of profit than is generally allowed for it. Our trade with the United States of America is profitable, but it has become so only of late years, since the condition of our *quondam* colonists has begun to approximate, in point of habits and in state of capital, to the circumstances of the well cultivated parts of Europe.

In regard to Spanish America, the features of our intercourse have been of late traced in very legible colours, and will tend to illustrate the scope of our observations. Until within these five years, the North Americans acted as middle men in our transactions with various parts of the Spanish settlements. Possessing the advantage of vicinity of situation, and of a neutral flag, the inhabitants of the United States were accustomed to re-sell a proportion of the manufactures imported from Britain to their southern neighbours, taking in exchange indigo, cocoa, coffee, sugar, and such other articles as the limited industry of the Spaniards enabled them to export. This intervention of the Americans was viewed with a very jealous eye by many of the ship-owners, of the merchants, and we believe we may add, by some of the ministers of this country. Many

Principles of commerce.

a calculation was made to shew how much greater would be our profit, were we to send our supplies direct to the Spanish settlements. At last the time came, when this envied traffic was thrown into our hands; the year 1808 having sealed the American ports by the embargo, and opened, in consequence of Bonaparte's usurpation, a free intercourse between Britain and the Spanish colonies. This was followed by a very extensive, or, as it was frequently termed, a *spirited* trade with the western hemisphere; and the amount of our exports was such, as to make a veteran writer on commercial subjects * declare, that, "throughout the effluxion of half a century, the year 1809 was the most prosperous." Unfortunately, however, a great part of this flattering exportation was never paid for. The North Americans had supplied the Spaniards with a cautious hand; but we, conceiving the market inexhaustible, poured in merchandise in immense quantities, and were first taught, by the bankruptcies of 1810, that the Spanish colonists were incapable of giving an equivalent for the goods which we had so liberally sent them. We have now learned, that a country may possess a fine soil, and a delightful climate, without the industry which is necessary to make her inhabitants desirable customers. Without attempting to compute the loss sustained in this quarter, or in the cultivation of newly settled colonies, such as Demerara or Trinidad, the general conclusion is, that much capital is sunk and lost in these countries, while, in trading with our European neighbours, the profits, though small, are steady and of quick return. Instead, therefore, of making war for sugar islands, or cotton plantations, the nations of Europe will, it is to be hoped, become in time alive to the importance of the vast profits which they may make, by trading with each other. In this country, we have no ground to dread the political power attendant on the successful prosecution of commerce by our neighbours; since our insular situation, and the extensive navigation inseparably connected with it, bid fair to assure to us the preservation of the empire of the sea. The Continent possesses, as we have very recently seen, the means of asserting its own independence; and if we analyse the sources of our national losses, we shall frequently find them to have originated more from mistaken measures at home, than from the power of our foreign enemies.

Our limits do not permit us to go farther at present into the general principles of trade; and we conclude, by referring those of our readers, who take an interest in such discussions, to the article POLITICAL ECONOMY. (χ)

COMMERSONIA, a genus of plants of the class Pentandria, and order Pentagynia. See BOTANY, p. 169.

COMMON. See AGRICULTURE.

COMMON CHORD, in Music, is a term applied to the most perfect combination of harmony that is known, and with which pieces of music generally end. In the

III 3 4
major key of C, these notes are C E G c, the inter-
V 6
VIII

vals between each adjacent note being placed above, those of every alternate pair are placed below the letters, and the VIII below these, is the whole interval between the extreme sounds; in which arrangement, it appears that all the seven concords, 3, III, 4, V, 6, VI, and VIII, except the VIth, are heard between the different notes of this chord, the major third being next the bass, to which circumstances are perhaps owing the peculiar effect and delight which this chord affords. If the two thirds be inverted, and the minor third placed next the bass, the chord is then called the common

3 III 4
chord minor, thus C E♭ G c. Here again 6 out of
V VI
VIII

the 7 concords are heard in the sounding of this chord, the minor sixth being now absent, and the minor third being placed next the bass, which circumstances probably occasion, or are closely connected with, the peculiar effect of this minor common chord. It seems rather a singular circumstance, that the VI should be wanting in the major chord, and the 6th wanting in the minor common chord. See our article CHORD. (ϱ)

COMMON LOGARITHMS, in musical calculations. These are often mentioned and used by the musical calculator, and, like all other kind of logarithms, they are *decimal values of a particular interval,* which is their unit, radix, or modulus. This interval is, in the present case, $\frac{1}{10}$th, $= 2033\Sigma + 40f + 176m$; and thus 1, in the *first* place of reciprocal common logarithms, represents $203.3\Sigma + 4f + 17.6m$, or $203.296855\Sigma + 4f + 18m$, being only $.700524\Sigma$ less than the isotonic III, or $\frac{1}{3}$ part of the octave. 1, in the *second* place, represents $20.33\Sigma + .4f + 1.76m$, or $20.395840\Sigma + m$. 1, in the *third* place of these logarithms, represents $2.033\Sigma + .04f + .176m$, or 2.04037022Σ, which differs only $.00020333\Sigma$ from the EXTAMERIDE, or $\frac{1}{301}$ VIII of M. Sauveur. If the recip. log. of the octave be .30103, then from the above $\text{VIII} = 612.000008\Sigma + 12f + 53m$. In like manner, the hyperbolic logarithms are decimals of an interval, whose ratio is $\frac{1}{2.7182818, \&c.} = 882.9718866\Sigma + 17f + 77m$. (ϱ)

COMMON MEASURES *of Musical Intervals.* In our article COMMENSURABLE *Intervals,* we have shewn, that, strictly speaking, there can be no such thing as a common measure or *unit,* by means of which all other intervals might be expressed in whole numbers or in decimals that terminate, or even that circulate or repeat; but that all such numbers expressing intervals (being logarithms of a particular species) will have decimal values indefinitely large, without any law in the continuation of the same being discoverable. Before the important invention of Lord Napier, and the construction of copious tables of logarithms, even the best mathematicians had but imperfect views of the relations and values of the prime ratios to which musical intervals are allied, and hence the many mistakes and inconsistencies in some of the best of the ancient writings on music, (see *Aristoxenian* COMMON MEASURES,) where they treat on the minute relations and values of intervals. Mersennus, for instance, concluded from his calculations, that $58\frac{1}{4}$ major commas made an octave, or $612\Sigma + 12f + 53m$, instead of $638.979614\Sigma + 12f + 55m$, the real value of so many major commas, which error was detected by Nicholas Mercator, who, according to Dr William Holder, (*Treatise,* 1st edit. p. 79,) in an unpublished manuscript, mentions having calculated by logarithms, that there were more than 55 commas ($55\frac{7}{11}$

* Mr George Chalmers. See his *Considerations on Bullion,* p. 1.

Common Measures.

$+ 12f - 2\tfrac{7}{11}m$) in an octave, and that he had "thence deduced an ingenious invention of finding and applying a least *common measure* to all harmonic intervals, not precisely perfect, but very near it."

Of the method or process by which Mercator obtained his series of *artificial commas*, answering to the 19 intervals, which Dr Holder has given as an extract from the manuscript, we are quite uninformed; but to us it seems probable, from the relation, that having calculated the number of commas to the nearest whole number in each case, answering to the 19 intervals mentioned, and found them as follows, (see Plate XXX. Vol. II.) viz. $c=1$, $\mathrm{E}=2$, $\mathcal{S}=3$, $\mathfrak{S}=4$, $\mathrm{S}=5$, $\mathbb{S}=6$, $t=8$, $\mathrm{T}=9$; 3rd$=15$, III$=18$, 4th$=23$, IV$=27$, and 5th$=28$; V$=33$, 6th$=38$, VI$=41$, and 7th$=46$; and VII$=51$, and VIII$=56$; and trying the relations of these by addition and subtraction of these commas, he thus found, that all those from c to T inclusive, exactly answered to the known and corresponding values and relations of these intervals, as found by the multiplication of the terms of their ratios, according to the equations given in our articles Apotome, Comma, &c.; and that again, from the 3rd to the 5th inclusive, the relations of these commas were proper to each other, though each was an unit too much, when compared by the proper additions and subtractions with the first part of the series; and, further, that from the V$^{\text{th}}$ to the 7$^{\text{th}}$ inclusive, the relations were true with respect to each other, but each was 1 comma more than the last part of the series, and 2 commas more than calculations from the first part would have given them; and, lastly, that the VII$^{\text{th}}$ and VIII$^{\text{th}}$ were 3 commas too great for comparison with the first part of the series: and thus probably it was, that the ingenious Mercator was led to reduce all the numbers to the first part, and so deduced his series of *artificial commas*, 1, 2, 3, 4, 5, 6, 8, and 9; 14, 17, 22, 26, and 28; 31, 36, 39, and 44; 48 and 53; answering to the 19 intervals above mentioned, as Dr Holder has given them.

We are not aware, that this mode of accounting for Mercator's unexpected discovery of the curious properties of the above series, was ever before published, or that the same attracted the notice of any curious person in these inquiries after Dr Holder, until the year 1807, when Mr John Farey sen. having extracted all the intervals contained in the Overend, and other manuscripts which he had perused, and, for the convenience of future reference, had, with considerable labour, reduced them all into *one notation*, by the intervals marked Σ, f, and m, as shewn in part in Plate V. in vol. xxviii. of the *Philosophical Magazine*, and in our 30th Plate in Vol. II. He then quickly discovered, that the number of m's in the last column of his Table, answered exactly to Mercator's number affixed to the same interval in Dr Holder's Treatise; and not only shewed the reason thereof, but his table of intervals, so arranged, furnished a far more accurate and extensive set of *artificial commas*, or under commas 612, to the octave, by extracting the number of Σ's in the first column.

It has also been shewn by that gentleman, that each of the columns of any notation of small terms, or intervals, so that negative signs are avoided, except when they affect a whole column, furnishes a set of artificial commas, as must, indeed, be evident, since there can be no *carrying forwards* of *whole* numbers from one column of notation to another, in adding, or *borrowing* in performing subtraction, as in the columns of pounds shillings and pence in money calculations, &c.; but each column, when there are no decimals, concurs in shewing, independently, the same results, as far as they can be expressed therein; yet carrying and borrowing are sometimes used, at the rate of .14966096, &c. between f and Σ, and of .007862405, &c. between m and Σ.

The m and f, in Mr Farey's notation, are the smallest intervals that are yet known, we believe; but two others, d and F, occur in our Table, Plate XXX. Vol. II. between the latter and Σ, the largest term of this notation; which term was fixed upon, on account of the many important relations which the schisma (Σ) bears to other intervals; but Mr Farey has tried other notations of these small intervals, as follows, viz. $612d + 1848f - 559m = \mathrm{VIII}$, $612\mathrm{F} + 624f - 559m = \mathrm{VIII}$, $306r - 294f + 53m = \mathrm{VIII}$, $559\Sigma + 53d + 171f = \mathrm{VIII}$, $279\tfrac{1}{2}r + 53d - 108\tfrac{1}{2}f = \mathrm{VIII}$, $65r + 429\Sigma + 53\mathrm{F} = \mathrm{VIII}$, $65c - 12\mathrm{R} - 31\Sigma = \mathrm{VIII}$, $55\tfrac{7}{11}c + 12f - 2\tfrac{7}{11}m = \mathrm{VIII}$, $53c + 29\Sigma + 12f = \mathrm{VIII} = 53c + 12r + 5\Sigma = \mathrm{VIII}$, $12\varphi + 41c + 41\Sigma = \mathrm{VIII}$, $12\text{ƒ}c + 53c - 31\Sigma = \mathrm{VIII}$, $12\text{ƒ€} \times 53c - 19\Sigma = \mathrm{VIII}$, $12\pi + 41c - 19\Sigma = \mathrm{VIII}$, $12\mathrm{D} = 41c - 7\Sigma = \mathrm{VIII}$, $12\text{ƒ} + 29\text{€} + 22\Sigma = \mathrm{VIII}$, &c. Whence several different sets of artificial commas, of 1848, 624, 612, 559, 429, 306, 294, $279\tfrac{1}{2}$, 171, $108\tfrac{1}{2}$, 65, $55\tfrac{7}{11}$, 53, 41, 31, 29, 22, 19, 12, &c. respectively, in the octave, might now readily be calculated by that gentleman's manuscript tables of intervals. The first of which, 1848, would give a set of artificial commas, considerably more exact in the very smaller intervals, owing to the largeness of the numbers, than that by Σ, adopted by Mr Farey; but the notation, whence it is derived, for other reasons besides the negative sign in all its terms, is less adapted to general use than Σ, f, and m, and they would not prove in the least degree more exact, for all intervals larger than Σ. The notation that is adopted, besides furnishing Mercator's and Farey's artificial commas, contains another set of these (or of artificial half notes rather) in its middle column, which shews the number of degrees, or half-notes, or the finger-key, (12 in the octave,) to which any interval belongs, and which is of very considerable use in the practice of musical computations.

The musical student must, however, be on his guard in using the above, and all other artificial commas, in his calculations; always remembering, that when *whole numbers* of *one* interval only are used, that the same have no fixed or precise values, but vary, within small limits, (if the number in the octave is considerable,) in expressing every different interval to which they are applied. Thus, if 1 of Farey's artificial commas be supposed exactly to represent the schisma, or Σ, (and these commas cannot represent any *smaller* interval): then in Σ, the alto comma or 1 is 1.000000 Σ; but in 10 for the minor comma, or €, the same is 1.00078624; in 11 for c, each is 1.0007020; in 12 for đ, each is 1,0006552; in 21 for ℰ, each is 1.007488; in 57 for S, each is 1.0033154; in 104 for T, each is 1.0035585; in 197 for III, each is 1.0037173; in 358 for V, each is 1.0036072; in 612 for VIII, each is 1.0036154, &c. differing *in every interval*, and so they would do, on the supposition that $\tfrac{1}{10}$ €, $\tfrac{1}{11}c$, $\tfrac{1}{12}$ đ, &c. any one of them exactly represented this artificial comma; and yet the curious and admirable properties of these numbers are such, that, by adding and subtracting, they truly represent, and with the utmost facility perform, all the operations with intervals, as certainly as the logarithms, or the multiplication or division of the ratios can do, except with intervals smaller than, or very nearly equal to, the unit, or which do not differ from one another by more than this unit, or by some fraction of it; and hence the great advantage of a series of large numbers, like 612 in the VIII. But multiplication can only correctly be performed on these artificial commas in some cases, and division in still fewer cases, and only where there are no remainders after such divisions; and, generally, where fractions of intervals arise, as in all tempered systems must be the case, they cannot be relied on, or used, except as a rough check on more correct and difficult calculations; but in all such cases, either the three columns, as Σ, *f*, and *m*, or logarithms of some sort, (as the decimals of any *one* interval always are,) to a sufficient number of places, must be used in all calculations relating to temperaments, or other fractional intervals. See *Aristoxenian* Common Measures. (ϱ)

COMMON Measures, *Aristoxenian*, in music. These were, as Dr Holder expresses it, (*Treatise*, 1st edit. p. 149,) "Irrational contrivances for expressing the several intervals." Aristoxenus, and many others among the ancients, having vainly imagined, that by dividing all the principal degrees of the scale, or consonances, into all their aliquot parts, that some one, in each of all these sets of parts, would be found exactly equal to each other; and this small interval, to be found in the aliquot parts of every other one, was the least *common measure* of all the intervals, which they laboured incessantly to find. Had the ancients been able as quickly and accurately to extract the 12th, 30th, 72d, &c. roots of numbers, as we now can, and even of still higher numbers, almost without limit, by the help of a Table of Logarithms, as we have shewn, as to the 104th, 197th, 358th, and 612th parts of the T, III, V, and VIII respectively, in our article Common Measures above, this delusion must quickly have vanished; and it would have appeared, as we have shewn in the article above referred to, that an artificial comma has *a different value in every different interval* to which it is applied. But owing to the tedious and difficult labour of extracting the roots of the terms of musical ratios by arithmetical operations, and the impossibility almost of avoiding errors therein, it was not difficult for those engaged in these calculations, to persuade themselves and their followers, that they had made out certain of their roots, thus obtained, to agree exactly. And thus it should seem, that the 12th part of the major tone, the 30th part of the diatessaron, or fourth, and the 72d part of the octave, were known by the common name of the *Aristoxenian common measure*, and were supposed by many to be equal, and adapted accurately to measure these and all other intervals; and though others showed the absurdity and impossibility of this abstractedly, or in some particular cases, yet the doctrine could not be exploded entirely, until after the invention of logarithms, when it quickly vanished, like a mist before the sun. We shall, however, subjoin the most useful particulars of these measures, viz.

		Σ m	Σ	Com. Logs.	VIII. Logs.	C. Logs.
$\frac{1}{30}$th of the 4th	=	8.489514 + 1	8.497376	.9958353,7545	.0138346	.771937
$\frac{1}{72}$d of the VIIIth	=	8.522869 + 1	8.530731	.9958190,2784	.0138889	.774967
$\frac{1}{12}$th of the T	=	8.689645 + 1	8.697507	.9957372,8980	.0141603	.790117

Which Table may prove of considerable use to those who wish to examine the ancient musical writings, and see the extent of the errors into which such authors may have been led, by assuming the three intervals above to be one and the same. The last of the above intervals has been called the *duodecimal of a tone*, and supposed to equal the first of them; from which it differs nearly 1 in the fourth place of com. logs. or not much more than $\frac{1}{5}$ Σ: the middle one appears to be less than an arithmetical mean between the other two. (ϱ)

COMMON Law, is that branch or department of the municipal law of any state which is opposed to the edictal, legislative, or other *written* constitutions. It consists of those maxims, customs, and established usages, which, originating in the peculiar genius, local situation, military institutions, or other circumstances of a people, take root and gradually spring up in every country. Hence the different parts of it are not of equal antiquity, but have been successively recognised, as the maxim, custom, or usage was found to be consonant to the public sentiment, and had received a general adoption. What, therefore, formed no part of the common law of a country at one period of its history, came afterwards to be acknowledged as an important feature of it; and thus passing from one acquisition to another, as the changes in society produced correspondent changes in the public sentiments and manners, the common law of most countries has insensibly accumulated into an extensive system. The gradual departure, however, from ancient manners, has, in some instances, undermined this department of law; while in others it has been directly overthrown by positive enactment. A history, therefore, of the common law of any country, must furnish information of no ordinary interest and importance, since it is nothing else than a developement of the changes which take place on the sense of justice and morality among any particular people, in consequence of the changes which have taken place on their condition.

It is opposed to the *lex scripta*, or written law of a country, not because it cannot absolutely be said to be unwritten itself, but because, unlike the edicts of emperors, or the legislative enactments of free states, it is not originally promulgated in a written form. It gradually comes, however, to be firmly embodied in the same form; and the recorded decisions of the supreme courts are the authentic and mighty volumes in which it is chiefly to be read. A labour so impracticable, indeed, no understanding, however undaunted or absurd, could be expected to undertake; so that in most states where the study of the law is not obstructed from views of oppression, recourse has been had at an early period, and afterwards successively continued, to "reported cases," or abridgments of the most important decisions. These, when disputed, are of course authenticated by reference to the records themselves.

We have said, that the common law is *chiefly* to be found in the records of the supreme courts; for there are other repositories of it, though greatly inferior in extent, and also to a certain degree, in authority. These are the ancient sages of the law, whose writings either precede the time at which the decisions of the courts began to be regularly recorded and preserved; or which supply the deficiences of the records; or, by the wisdom and analogy of the observations they contain, have acquired an authoritative respect bordering on veneration. Thus, in England, Glanvil, Fleta, Littleton, and even so late a writer as Sir Edward Coke, are regarded as oracles of the common law. However, the authority of such writers depends chiefly upon the belief, that they are the faithful reporters of cases which, either by reason of their antiquity, or other causes of an accidental nature, are not now to be found upon record; and that they speak correctly the language of the maxims, customs, and usages of the times to which they severally relate.

In most countries of modern Europe, the civil and canon laws constitute likewise, more or less, a part of the common law. "But," as remarked by Blackstone, "all the strength which these laws have obtained in England, or in any of the other kingdoms of Europe, is only because they have been admitted and received by immemorial usage and custom in some particular cases, and some particular courts; and then they form a branch of the *leges non scriptæ*, or customary laws; or else, because they are in some other cases introduced by consent of parliament, and then they owe their validity to the *leges scriptæ*, or statute law."

In Scotland, the words *common law*, appear to have been sometimes used as synonymous with the civil or Roman law. Thus in statute 1540, c. 69; 1585, c. 18; 1587, c. 31, they are so used; and sometimes they employ the civil and canon law together: as in 1540, c. 80, and 1551, c. 22. It by no means follows, however, that either of these bodies of foreign law ever constituted, indiscriminately, and of their own proper authority, the common law of the country. On the contrary, when the common law proper to the country is meant, the statutory phrase is, *the common laws of this realm*, as in statute 1503, c. 79, and 1584, c. 131, where the ancient maxims and usages of Scotland, whether originating in the Roman, the canon, or the feudal institutions, or in whatever other source, are understood. So that, in the former instances, the phrase seems to resolve into a mere inaccuracy of expression. (J. B.)

COMMONS. See Parliament.

COMMONWEALTH. See Britain.

COMNENA Anna. See Anna Comnena.

COMO, Comum, or Novocomum, is a town of Italy, and capital of the department of Lario, beautifully situated on the southern extremity of the Larian Lake, or the Lake of Como. Excepting towards the lake, it is surrounded on all sides with fertile hills, and stands at the bottom of three green and wooded conical eminences, the middle one of which is crowned with a crested castle, stretching its ramparts down the declivity.

The houses are chiefly built of stone, and the public edifices are magnificent. The cathedral, which was repaired at the expence of Innocent XI. is of a mixed style of architecture, and is constructed of white marble. The front is in a light Gothic style; the nave is supported by Gothic arches; the choir and transepts are adorned with composite pillars; and the whole is surmounted with a dome over the centre. There is a statue of Pliny the Younger, who was born in Como, placed in a niche in the front of the cathedral, with basso relievos, alluding to his writings, and inscriptions in his honour on each side of the grand entrance. Besides the cathedral, there are about 12 other churches, some of which are ornamental to the town. That of St Giovanni is decorated with several columns, which are supposed to have been taken from a portico which Pliny mentions as having been built by his wife's grandfather Fabatus. There are likewise in Como three colleges of considerable reputation, and three public libraries.

Como is a town of great antiquity, and appears to have been founded by a colony of Gauls under Brennus. Its importance was increased by a colony of 500 Greeks, all of whom were persons of quality, who were carried there by Julius Cæsar. In the time of Pliny it appears to have been a flourishing and opulent city, surrounded with large and magnificent villas, and decorated with temples, statues, porticoes, and pillared gates.

The inhabitants are very industrious, and have the character of making good soldiers. Several manufactures of cotton, silk, and velvet, are established in the town, and a small trade is carried on with the Grisons. Mr Eustace, who visited this town in 1802, makes the population 20,000, whereas Tynna, in his *Almanach du Commerce, pour* 1811, where the population of French towns is generally exaggerated, makes it only 7000. East. Long. 9° 5′ 41″, North. Lat. 45° 48′ 22″. See the Rev. John Chetwode Eustace's *Classical Tour through Italy*, vol. ii. p. 363, &c. Lond. 1813; *Viaggio ai tre Laghi Maggiore, di Lugano, e di Como, &c.* di Carlo Amoretti. Milan, 1803; and *Tableau Historique Statistique et Morale de la Haute Italie, par* Ch. Denina, p. 248, 388. Paris 1805. (π)

COMO, Lake of, the *Lacus Larius* of the ancients, is a lake of Italy, which stretches between two chains of mountains at the foot of the Alps. It is about fifty miles long, from three to six broad, and from 40 to 600 feet deep. It is of a serpentine form, and has its banks indented with numerous creeks and harbours. It is subject to sudden squalls, and to violent and unexpected swells. The lower regions of the mountains with which the lake is encircled, are covered with olives, vines, and orchards: the middle regions are encircled with groves of lofty chesnuts, and the higher regions are either downs or forests of pine and fir, the most elevated ridges being either naked or crowned with perpetual snow. "Their sides," says Mr Eustace, "are seldom formed of one continued steep, but usually interrupted by fields and levels, extending sometimes into wide plains, which supply abundant space for every kind of cultivation. These fertile plains are generally at one third, and sometimes at two-thirds of the total elevation. On or near these levels are most of the towns and villages that so beautifully diversify the sides of the mountains. Various mines of iron, lead, and copper, are now, as they were anciently, spread over the surface of the Larian territory, and daily opened in the bowels of its mountains; besides quarries of beautiful marble, which supply Milan and all the neighbouring cities with the materials and ornaments of their most magnificent churches."

At a village called Pliniana is the intermittent fountain, so minutely described by Pliny. It bursts from a rock in a small court behind the house, and increases and decreases thrice every day, although the ebb and flow are sometimes irregular.

The principal places worthy of being noticed by a traveller are, the little wooded island of St Giovanni, the villages of Balbiano, Lenna, and Villa, the last of which is supposed to be the site of Pliny's villa; the promontory and village of Bellagio, the village of Cadenabbia, which should be the head quarters of a traveller who wishes to explore the lake; Bellano on the opposite side of the lake; the cavern of L'Orrido; the village of Capriano, supposed by some to be the real situation of Pliny's lower villa, the stream and cascade of Latte, and Menaggio from which there is a full view of the lake from Bellagio to Garedona and Domaso.

Comocladia || Company.

Beyond Domaso the lake of Como receives the Adda, after which its channel is narrowed, and it takes the name of the Lago di Chiavenna. See the works quoted in the preceding article. (*π*)

COMOCLADIA, a genus of plants of the class Triandria, and order Monogynia. See BOTANY, p. 97.

COMORA ISLES, is a cluster of islands situated in the channel of Mozambique, between the northern extremity of Madagascar and the coast of Zanguebar in Africa. The principal islands are Johanna, Mayotta, Mohilla, Angazi, and Comora. The Portuguese, by whom they were discovered, treated the inhabitants with such cruelty, that almost all those who have since visited those islands have been either massacred or ill received. More recently, however, the inhabitants, who are negroes of the Mahommedan religion, are said to entertain European seamen with considerable humanity. The islands abound in horned cattle, hogs, and sheep, and produce sweet and sour oranges, citrons, bananas, honey, sugar canes, rice, ginger, and cocoa nuts. E. Long. between 43 and 45°, N. Lat. from 1° to 14°. (*j*)

COMPANY, (Fr. *compagnie*, derived from the Latin *cum* and *panis*,) means properly "an assemblage of several persons in the same place, or for the same purpose." In the sense in which it is generally taken, and in which it becomes an object of explanation in this article, it denotes an association of a number of merchants. We say a "number," because the word *partnership* is generally applied to a limited association. Company, besides, is currently understood as the designation of a body of men conducting trade, with particular privileges, or under specific exemptions;—partnerships, on the other hand, have no particular privileges.

A branch of commerce carried on with an uncivilized people may require, particularly in the commencement, more protection than the circumstances of unconnected merchants can afford. In such cases, a fort and a garrison may be necessary; as well as a diplomatic agent, for the purpose of maintaining a good understanding with the government of their rude neighbours. These considerations, varying materially in different quarters, have given rise to mercantile associations of two kinds; regulated companies, and joint stock companies. The former should hardly be called companies, according to the current acceptation of the word, as they are obliged to admit any person properly qualified, who will pay a moderate fine, and submit to their regulations. This done, the new member proceeds, like his predecessors, to trade on his individual capital, and at his own risk. A regulated company, therefore, bears a great resemblance to an incorporated trade in a town, the object in either case being the exclusion of all those persons who have not performed certain specific obligations. The fact, however, is, that improvements in commerce have so much facilitated the admission of merchants into our regulated companies, that little attention is paid by the public to the nature of their constitution. Their names even are not familiar to mercantile men. The regulated companies in this country are five in number, and are called the Hamburgh, the Russia, the Eastland, the Turkey, and the African company.

Turkey company

In looking back to former records, we are led to judge, from the complaints of manufacturers and others, that these companies possessed and exercised power in a manner very different from what we see at present. The Turkey company, for example, enacted by a bye-law, that all British goods for that empire should be shipped in their vessels exclusively. Another bye-law purported, that no persons who were not freemen of London should be allowed to become members of the company. The pretext for these regulations was the necessity of excluding from the traffic individuals whose conduct might give offence to the Turks. The restrictions, however, were found very injurious, and abrogated, in a great measure, by an act of parliament in 1753, which laid open the trade to persons out of London. In regard to the Eastland and the Russia Companies, the admission is now so easy as to be procured for a few pounds.

African company.

The latest institution in the shape of a regulated company was the African, established by act of parliament in 1750. The object of it was to provide for the maintenance of certain forts and garrisons on the western coast of Africa. A sum, generally L.13,000, was annually voted to them for that purpose by parliament; but in spite of all the precautions taken in drawing up the charter, the directors of this association have been accused of neglecting the charge entrusted to them.

Joint stock companies.

Joint stock companies come next to be considered, and will be found a more important and interesting subject. Their leading characteristics, as distinguished from private trading companies, are two; exemption of the individual member from responsibility beyond a specific sum, and liberty to sell the share held in the capital whenever he thinks proper. This limitation of risk, coupled, as it generally is, with exemption from trouble, recommends joint stock companies to many persons who, from situation, would not otherwise think of vesting money in trade. These persons, however, must not flatter themselves that any united company can long maintain a competition with the vigilance and activity of private traders. The directors find themselves the managers rather of other persons' property than of their own, and abuses infallibly creep in. We have seen under the article COLONY, the failure of joint stock companies in one nation after another, in a kind of regular succession. Such has likewise been the lot of the English African companies, of whom we have had, from first to last, no less than four distinct associations. The South Sea company were exempt from one great article of expence, the maintenance of forts and garrisons, but their example is equally discouraging as that of others. Their stock-jobbing projects belong to history, and are too legibly written in characters of national misfortune to require animadversions in this place. But their mercantile arrangements are less generally known. Aided by an exclusive privilege, they engaged to supply the Spanish West Indies with negroes, and were allowed, as a special advantage, to send an annual cargo of merchandise to that far-famed market. Yet, of ten annual voyages of this description, one only was profitable to the company as a body, whatever may have been the individual gains of their servants. The result was, that the company petitioned and obtained leave from government, to treat with the court of Spain, for a consideration, for the relinquishment of the privilege of importing this annual cargo. The Greenland trade being undertaken by this hopeful association, was conducted in the same style; and was wound up in 1730, with a loss, in the course of eight years, of L. 237,000. As many persons are not apprised how South Sea stock continues a valuable property, after the total failure of the projects of the company, it is proper to add, that their capital (nearly thirty-four millions sterling) was lent to government. In 1722, it was agreed that half this sum should be put on the same footing as

South Sea company.

other government stock, and exempt from the debts or losses attendant on mercantile adventure. In 1733, the same character was given to a farther portion of the stock, and in 1748 to the whole.

Hudson's Bay company.

The Hudson's Bay Company have been cited as an example of successful management on the part of a joint stock association. The fact, however, is, that their transactions are of very limited compass, and much less productive of profit than has been represented. Neither are they an example of the benefit of exclusive privileges, their charter, which was dated in 1670, being from the crown only, and not confirmed by parliament. It consequently contains no legal prohibition of the interference of private traders. Their transactions accordingly fall more properly under the description of well-managed partnerships, than of extensive companies.

East India company.

Our first India company was chartered, not by parliament, but by the crown, in 1600. It became a joint-stock association in 1612. In course of time, private traders, questioning the legality of a charter not confirmed by parliament, ventured to interfere with their commerce, and exposed them, towards the end of the seventeenth century, to the losses attendant on a formidable competition. In 1701, the charter having expired, the public saw the unusual occurrence of two joint stock companies pursuing the same branch of commerce. In 1708, they were consolidated into one company, under their present name; and in 1711, the competition of private traders was finally removed. Soon after the middle of last century, this company gradually augmented their dividend from 6 to 10 per cent. In 1767, government laying claim to their territorial revenue, as the property of the crown, the company bargained for its retention, by agreeing to pay government a sum of L. 400,000 a-year. The most flattering accounts of their finances were exhibited; but unfortunately their debts still continued on the increase. Great disorders prevailed in the management of their India affairs; and the expence of war with Hyder Ali, reduced them to the necessity of applying to government for relief. Since that time, the wars with Tippoo, Scindiah, and Holkar, along with the continued disadvantages inseparable from a joint stock company, have reduced their affairs to that situation, in which most associations of the kind have been obliged to make their exit. The complication of their accounts, and the popular notion of wealth still attached to the name of India, have long prevented the public from being aware of their real condition. And government, appreciating the utility of many of their institutions in India, as well as desirous of avoiding a shock to public credit, have conducted the change, now become necessary, with much delicate attention to the company. The internal government of India, and the China trade, their only lucrative branch, have accordingly been left in their possession.

Such being the general, we may almost say the universal, lot of joint stock companies, it becomes a question, whether such institutions are, under any circumstances, advisable? In the case of a new trade established with a remote and barbarous nation, Dr Smith approves of a temporary monopoly, on the same principle as of the monopolies granted by patent for the invention of machinery. But on the expiration of a specified term, the monopoly ought certainly to close, and the public buildings that may have been found necessary, should be taken over by government, the trade being laid open to the public at large. The Abbé Morellet gives a list of fifty-five joint stock companies for foreign trade, established in different countries of Europe since 1600, all of whom have been unsuccessful. In fact, the only mercantile undertakings which it seems possible for a joint stock company to carry on advantageously without an exclusive privilege, are those of which all the operations are capable of being reduced to mere routine, that is, to the application of a few plain and constant rules. The branches enumerated by Dr Smith as coming under this description, are four in number: banking—insurance from fire, sea risk, and capture—the making of navigable canals—and, lastly, the supplying a great city with water. This enumeration was apparently suggested, more by an observation of the branches which had actually succeeded in England, than by any deduction from previous reasoning. The making of a navigable canal, or of extensive water-pipes, are attended with no peculiar facilities beyond the excavation of a dock, a speculation not admitted into Dr Smith's list of eligible undertakings. On the other hand, the insurance of merchantmen against capture, is one of the most varying and difficult calculations in the whole circle of mercantile adventure. We prefer, therefore, Dr Smith's general rule to his particular list, and are disposed to infer, that as society advances, and the principles of different branches become better understood, the appropriation of the vast sums which characterise the capitals of joint stock companies, will be found to embrace a greater variety of undertakings. It becomes in every age more generally the practice, to divide a large concern into various departments, and to make contracts on the plan of performing work by the piece. The consequence is a succession of checks, by these improved arrangements, to the mismanagement which is inseparable from a public board, so long as the conduct of affairs remains discretionary. At the same time, the possession of exclusive privileges should be granted with a very sparing hand; and, in a recent case of this description, the West India Dock Company, we have understood, that the obligations imposed on the trade at large have given rise to various complaints.

In looking around to our continental neighbours, we see frequent examples of loss incurred in consequence of joint stock associations undertaking branches of trade unsuitable to the circumstances of their respective countries. Sweden and Denmark, for example, are too bare of capital for so remote a trade as that of India, where the returns seldom come round in less than two years. Their true policy would be to occupy themselves with a traffic in their own neighbourhood, and with countries such as England and Holland, where the risk is small, and the payment prompt. The arguments in behalf of joint-stock companies, founded on the plea of an impossibility of otherwise managing the trade, should be received with great caution. The Portuguese, certainly not the most temperate of European nations, conducted the India trade above a century on the plan of separate adventure. In China, accounted the most difficult of all countries to manage, the Americans of the present day find no particular inconvenience from dispensing with the regulations of a united company. M. Say, one of the most enlightened disciples of Dr Smith, in admitting (vol. ii. p. 196) the peculiarity of Chinese customs, maintains, that individual merchants are just as likely to behave with the requisite caution, as the officers or agents of an established association. He enters, concisely indeed, but with much force of argument, into the various disadvantages of

Company.

privileged companies. It is, he says, a bad sign in the outset, that special encouragement should be required for the purpose of giving a particular direction to a portion of the national capital. After all that has been said of the profit attendant on a direct intercourse with such countries as India and China, does it appear, he asks, that the nations who buy tea and piece goods at second hand, pay much more for them than the original importers? On making a strict analysis, it will be found that the chief profits of a privileged company are extracted from the pockets of their own countrymen. Whatever sum is paid by a consumer beyond the rate at which a free traffic would supply the article, is so much money lost to the public. Moreover, no concerns are more liable to suffer by the langour attendant on the proceedings of a board composed of men acting for others, than the remote and complicated affairs of India. A director of the French East India Company asked M. La Bourdonnaye, "how it had happened that he had managed his own affairs so much better than those of the Company?"—"The reason," said the other, "is plain; my own affairs are managed according to the judgment formed on the spot, while, in regard to public concerns, I was obliged to follow orders from a distance."

In investigating the motives which have so frequently induced governments to lend themselves to the views of persons projecting exclusive companies, we recognise the influence of two prominent reasons; first, a prospect of gain is held forth without discovering at whose expence; and, in the next place, these flattering profits may be reduced in the most plausible way to numerical calculation, while the consequent loss, being indirect, obscure, and general, wholly escapes observation. The general result of the facts and reasoning brought forward in this article may be expressed as follows: Exclusive privileges, if they ever were advisable, become less and less necessary as society advances. On the other hand, the exemption from unlimited responsibility, and the unrestrained permission to bring to sale a share in the property of a company, the two principal features in the constitution of a joint stock association, become more and more applicable as improvements take place. Both alterations are in correspondence with that admirable system which an intimate knowledge of political economy opens to the mind of the attentive observer. Exclusive privileges are at variance with that liberty which constitutes the basis of trade; while the exemptions which we have specified are merely examples of the extension of the principle. It has been thought expedient to make every partner in a private mercantile house responsible to the creditors of the concern to the last shilling of his property; a precaution rendered necessary by the unacquaintance of the public with the amount of property invested in the concern. But in the case of a public body, the capital is matter of notoriety, and the responsibility of the individual partners admits of limitation, without injury to the creditors of the company. (χ)

Company || Complement.

COMPASS. See MAGNETISM.

COMPASSES. See DRAWING INSTRUMENTS.

COMPENSATION BALANCE. See TIMEKEEPER.

COMPLEMENT, in music, is applied to such intervals as, with some other given one, make up the octave, or eighth; thus, if a major third be given, as CE, its complement is the minor sixth E *c*; if a minor third CE♭, its complement is the major sixth E♭*c*, &c.; and it may be proper here to note, that a *major* interval is always the complement of a *minor* one, and *vice versa*; and that these intervals are always expressed by the same letters, but in reversed order, as above. It may be proper further to remark, that if any interval be a concord, its complement is the same also; and if a discord, its complement is a discord also: and, that if any interval be tempered flat or sharp, its complement has just a similar temperament sharp or flat, or the reverse of the former; thus, $V - \frac{1}{4}c$, has $4th + \frac{1}{4}c$ for its complement, in the mean tone system; $V - \Sigma$ has $4th + \Sigma$, and $III + 7\Sigma$ has $6th - 7\Sigma$, for their complements, in Farey's *Equal Temperament*. (ϱ)

COMPONENT PRIMES, in music, is applied to the integers 2, 3, and 5, which enter into the composition of the ratio of any interval; thus, of the major comma, whose ratio is $\frac{80}{81}$, the component primes are $\frac{2^4 \times 5}{3^4}$, or, the 4th power of two multiplied by 5 for a numerator or least of the terms, and the 4th power of 3 for a denominator, or largest of the terms. (ϱ)

COMPLEXION

Complexion.

GIBBON has remarked, that the extraordinary phenomenon of the great and extreme variety in the human complexion, as in some instances it appeared to proceed from the influence of climate, and in other instances to resist it for a long series of years, which has roused and exercised the speculation of modern philosophers and theologians, was passed over, almost unnoticed, and certainly uninvestigated, by the ancients. Their attention was indeed called to the general and striking fact, that under the burning climates of the globe, the human complexion was of the darkest hue: the fable of Phaeton, invented or embellished by the poets, contained in it such an easy and satisfactory solution of this circumstance, that in its more sober and philosophical interpretation, it was adopted and acquiesced in by the natural historians of antiquity; but neither their opportunities of information enabled them, nor, had they possessed these, would their mode of philosophising have led them to detect, and speculate on the exceptions to the general fact, that the blackness of the human complexion increased or diminished according as the country approached or receded from the equator.

Opinions of the ancients.

Even the blackness of the Ethiopian, (for this name they seem to have given to all the nations who had this complexion, whether they had inhabited Africa or Asia), though it excited the wonder and astonishment of the ancients, did not induce them to enter very fully or minutely into the investigation of its cause. Hippocrates, Aristotle, and Pliny, merely touch upon it rather individually, than with any settled purpose of treating it in a full and satisfactory manner. Pliny, indeed, from the information which the Romans, by their conquests in Gaul and Germany, had gained respecting those nations, was enabled to illustrate and to strengthen the hypothesis which was contained in the fable of Phaeton, and, coinciding with it, in ascribing the

Complexion.

blackness of complexion, and crispature of hair, which distinguished the Ethiopians, to their vicinity to the sun, he attributes the fair complexion and yellow hair of the northern nations of Europe, to the coldness and moisture of the climate under which they lived.

This hypothesis, so conformable to the most notorious and well-established facts, and which seemed to be firmly grounded on philosophical principles, remained for a long time undoubted and undisturbed, amidst that superior information and more strict and scrupulous mode of reasoning, which entirely destroyed, or greatly modified, the conjectures and opinions of the ancients on other points of physical science; it was even strengthened among the moderns, by the circumstance, that religion was supposed to lend its authority to its truth. A disposition and tendency to call it in question, and certainly an absolute rejection and disbelief of it, cannot, we apprehend, be traced farther back than the end of the 17th century; and what is worthy of remark, one of the first who maintained that climate alone could not produce the negro blackness, was Mr Boyle,—a name which ought to secure this opinion equally, and at once, from the charge of want of philosophy and want of religion. Boyle's *Works, abridged by Shaw—Experiments and Observations on Colour*, vol. ii. p. 42.

The full and methodical discussion of this curious and important subject, requires that we should call in the aid of physiology, as well as of the geographical history of man; and that we should, in the first place, endeavour to ascertain the seat of colour in the human body; secondly, that we should examine the different hypotheses which have been thrown out, to account for the *immediate* cause of colour; the varieties of human complexion ought next to be collected and classed; and, finally, the influence of climate in producing these varieties, must be investigated and ascertained.

On the seat of colour in the human body.

I. The human skin, till the time of Malpighi, was supposed to consist only of two parts; the cuticle, epidermis, or scarf-skin, and the cutis or real skin; but that anatomist, about the middle of the 17th century, discovered between these a cellular texture, soft and gelatinous, to which the names of *rete mucosum*, and *corpus reticulare*, have been given. He demonstrated the existence of this membrane at first in the tongue, and in the inner parts of the hands and feet; but by his subsequent labours, and also by those of Ruysch and other anatomists, it has been proved to exist between the epidermis and the cutis in all parts of the human body.

Malpighi, on the discovery of this membrane, offered a conjecture respecting the cause of the colour of negroes: he supposed that this membrane contained a juice or fluid of a black colour, from which their blackness arose: the actual existence of a black pigment has been since ascertained, but has never been procured in sufficient quantity to admit of minute and analytical examination.

The rete mucosum is of very different colours in different nations; and the difference of its colour so completely agrees with the difference of their complexions, that there can be no doubt that it is the sole, or at least the principal seat of the colour of the human complexion. Its thickness varies in different parts of the body; and the depth of its colour, for the most part, is in proportion to its thickness. Where the cuticle is thickest, there it is also found of the firmest and thickest texture; and it is most easily detected in the palms of the hands, and in the inner parts of the fingers, and on the soles of the feet. There appears, however, one exception to this general rule. According to Kaaic, "in pudendis vero tenue, sed fuscum ita, ut negares de Europæi cute detractum esse." *Perspiratio dicta Hippocrati, per Universum corpus Anatomice illustrata, Auctore* Abrahamo Kaaic, M.D. Lug. Bat. 1738, p. 21.

Although this circumstance of the different colours of the rete mucosum corresponding exactly with the different complexions of the human race, seems satisfactorily to fix the seat of colour in that membrane, yet some authors are of opinion, that the black complexion of the negroes arises, partly at least, from the cuticle. This opinion is particularly maintained by Dr Mitchell, in his "*Essay on the Causes of the different Colours of Persons in different Climates.*" Phil. Trans. abridged by Martyn, vol. x. p. 926. "The cuticle of negroes," he says, "is much thicker than it is in people of a fair complexion; and hence, it cannot so easily or perfectly transmit the colour of the cutis through it." But it is evident, that even allowing the fact on which this reasoning is founded to be true, namely, that the cuticle of negroes is much thicker than that of fair complexioned people, it will rather militate against, than support the inference which he draws from it; since, if the thickness of the cuticle weakens its power of transmitting colour, the black colour of the rete mucosum can have little or no effect in producing the black complexion of the negroes.

But though the cuticle cannot, in this manner, give rise to the colour of the human complexion, there is reason to suppose, that in some degree, and in some cases, it contributes to this effect. Kaaic maintains, that this membrane, even when separated from the rete mucosum, is found to possess different colours in different nations; and that it also varies in men living under the same climate. That this variation does not arise entirely from different degrees of exposure to the sun and air, clearly appears from an experiment which this anatomist made. He macerated the cuticles of twins, and separated the rete mucosum; the colour of the cuticles he found to differ in a considerable degree.

The black colour of the negroes is destroyed by several causes; indeed whatever destroys the rete mucosum destroys it, as wounds, burns, &c. and as this membrane is never reproduced, the scar remains white ever afterwards. Hawkins, in his *Travels into the Interior of Africa*, (p. 120.) mentions, that the land-cloud of Africa, called by the Portuguese *ferrino*, changes the black colour of the negroes into a dusky grey; according to some other authors, the change is into a red copper colour. At Darfur, a species of leprosy prevails among the natives, which they call *borras*, and which gives them the appearance of being pie-bald, changing to a white colour parts both of their skin and their hair. *

There are also several instances of the colour of negroes being either entirely or partially changed from the operation of causes, which cannot be detected or explained. A boy who was born in Virginia, of black

* Browne's *Travels in Africa, Egypt, and Syria*, p. 332.—There are several kinds of fish in the West Indies, which, when eaten, alter the colour of the negro. Dr Clark of Dominica particularly notices this:—"A singular effect of fish poison, is to remove the epidermis in patches or spots, about the hands and feet, which continue white in people of colour, and of a pale yellow colour in white people, for life.—*Medical Facts*, vol. vii. And Dr Isert saw a negro, in his travels through Guinea, whose hands and feet were perfectly white, in consequence of a severe illness, probably occasioned by eating poisonous fish.—*Reise nach Guinea*, p. 175.

parents, continued of his native colour till he was three years old: at that period a change of colour began to take place, though the health of the boy continued good, and there was no assignable cause for the alteration in his food, or mode of life. At first white specks made their appearance on his neck and breast, which soon increased in number and size; from the upper part of his neck down to his knees, he was completely dappled; his hair was also changed, but not to the same degree, since, though some parts of it were white, in general it retained the black colour and crispature of the negro. The colour of those parts of his body which had undergone the change, was of a more livid white than is found among the fairest Europeans; nor did the flesh and blood appear through these parts of his skin so clear and lively as through the skin of white people. He was not liable to be tanned. *Philosophical Transactions*, vol. xix. p. 781.

It has been already mentioned that burning renders the negro skin white; and this cause might have been supposed to have operated in the following instance, had it not been expressly mentioned that the person was always well clad, and that the parts exposed to the kitchen fire were not more particularly affected than such parts as were not so exposed. A cook-maid, a native of Virginia, whose skin was originally as dark as the most swarthy African, underwent a change of complexion when she was about 25 years of age: this change made its first appearance on the skin near the finger nails; the skin of the face, particularly near the mouth, was afterwards affected; and the change gradually proceeded, till at last four parts out of five of her face and body became white; her neck and back remained the blackest. This change was different in its nature from that of the former case; for, in this instance, the skin became transparent, similar to that of a fair European, so that blushes could be discovered, and freckles took place; the hair was also changed to white on those parts of the body which had become white, while it continued black on those parts which preserved their native colour. *Philosophical Transactions*, vol. xli. p. 176.

But the case most similar in its nature, and most particularly described, is given in the *Manchester Transactions*, vol. v. part 1. p. 314. The paternal grandfather of Henry Moss, (the person in question,) was born in Africa, and married a native Indian of Pennsylvania. His father married a mulatto, born of an African father and an Irish mother. His maternal grandfather was born in Africa. He himself, till he arrived at the age of 40, was of as dark a complexion as any African: a change of colour then began to take place; it commenced at the skin near the root of his finger nails. It is remarkable that the change proceeded most rapidly and regularly, during the summer season; during winter it either was entirely suspended, or went on so slowly as scarcely to be perceptible. He felt, or fancied himself, more sensible to variations of temperature, after this change of colour took place, than he had been before. The change in the colour of his hair proceeded along with the change in the colour of his skin; and wherever it became white, it became also soft, like the hair of Europeans, and could be drawn out to the length of several inches. Mr Fisher, who transmitted the account of this phenomenon, ascertained that the change of colour was not external, but a change of the *rete mucosum*; for when he pressed the skin it appeared white, and on the removal of his finger, it was suffused with red, as in Europeans.*

The oxymuriatic acid has a temporary effect on the black pigment, which exists in the *rete mucosum* of negroes. Dr Beddoes subjected the fingers of a negro to the action of this acid; the skin was whitened, but the black colour returned in a short time. This experiment has been repeated on the feet of a negro. They were kept for a considerable period in water, impregnated with oxymuriatic acid, which deprived the rete mucosum of its colour, and rendered it nearly white; but in a few days the black colour returned with its former intensity.

II. Various hypotheses have been suggested to account for the *immediate* cause of the black complexion of negroes, by Mecket, Pauw, Walter, Kant, Blumenbach, Rush, and Humboldt.

Hypotheses of Mecket and Pauw.

1. The hypotheses of Mecket and Pauw nearly coincide, and seem to have been derived from an observation of Herodotus. This historian asserts that the spermatic fluid, both in the eastern and western Ethiopians, is not white as in other men, but black like their skin. (*Herodotus Thalia*, cap. 101.) This opinion is expressly denied by Aristotle, but it is supported by the authority of Le Cat, in his *Traitè sur la Couleur de la Peau*. From this colour of the spermatic fluid, Mecket and Pauw supposed that all the other fluids of the negroes received a dark tinge. The former believed that the liquor which colours the medullary substance of the brain, was darker coloured in the African than in the European; this he supposed arose from the colour of the spermatic fluid, and being secreted by the cutaneous nerves into the viscous reticular substance, contributed towards the dark complexion of the mucous membrane.] But Soemmering expressly denies the allegation on which this hypothesis rests: he could not observe the smallest difference in colour, either in the ceneritious or medullary parts of the brain of an African and European; and, notwithstanding the authority of Le Cat, the blackness of the spermatic fluid of the negro may very justly be doubted.

Of Walter.

2. Professor Walter is of opinion, that the blood of negroes is of a darker colour than that of Europeans, and that this is the cause of their dark complexion. This opinion is also maintained by Town, in his Paper on the Blood of Negroes, in the *Philosophical Transactions*; and Professor Soemmering seems rather disposed to adopt it; but the fact is very questionable. Professor Camper asserts that the blood of negroes is not darker coloured than is frequently found among Europeans; and Dr Winterbottom, who must be allowed to be a competent judge on this question, expressly maintains, "that there is no perceptible difference in the colour of the blood of an African and European." Winterbottom's *Account of the native Africans in the neighbourhood of Sierra Leone*, vol. i. p. 191.

3. Kant, Blumenbach, and Humboldt, offer different

* It is probable that similar changes of colour frequently take place among the negroes, in their native land, without any assignable cause. Mr Winterbottom says, "it is not uncommon to see persons, whose skins have undergone a change from black to white, the appearance being confined to only a small part of the body. Sometimes one or both hands and feet are spotted black and white; sometimes they are entirely white. The Bullones compare this disease to a caterpillar, variegated black and white, which they call *unnah*, and hence they name the disease *ker'unnah*, or spotted worm. This change of colour is not produced by any injury done to the skin. The natives appear ignorant of the cause of this curious phenomenon. Some blame particular kinds of food, while others more prudently confess their ignorance."—Winterbottom's *Account of Sierra Leone*, vol. ii. p. 173.

Complexion.

Hypotheses of Kant, Blumenbach and Humboldt.

modifications of a chemical hypothesis, to account for the dark colour of the *rete mucosum.* The first of these authors supposes that the blood of negroes abounds in iron, which is precipitated into this membrane by the phosphoric acid. Blumenbach is of opinion, that the carbon which abounds in the body is thrown off by the *cutis vera,* united with hydrogen, but is decomposed by the access of the oxygen of the atmosphere, while the carbon remains fixed in the *rete mucosum;* and Humboldt ascribes the dark complexion of the Indians of South America to the abundant deposition of carburetted hydrogen in the *corpus mucosum;* or *reticulatum* of Malpighi; this, he supposes, not only is the proximate cause of darkness of complexion, but also of the fact, that those races in which it exists retain their native colour, even under the influence of a colder climate.

4. The remaining class of hypotheses rest on a different foundation. Blumenbach, besides giving it as his opinion that the proximate cause of the dark colour of the rete mucosum is the abundance of carbon which remains fixed in that membrane, endeavours to account for the secretion of this substance in such quantity. Hot climates, he says, exert a great influence on the liver: an unnatural state of the bilious secretion being thus produced, and increased through many generations, the vessels of the skin secrete a greater abundance of carbon than in colder climates. But this hypothesis is extremely weak and ill-founded; besides involving the idea that the negro race are constantly labouring under hepatic disease, it is directly contradicted by the fact, "that bile has no power in producing a permanent change in the colour of the skin; and sickness, which in hot climates causes the skins of Europeans to assume a yellow hue, changes that of the African to a lighter colour." Winterbottom, vol. i. p. 190.

Of Rush.

Dr Rush has advanced an hypothesis of a similar nature to that just noticed, but still more weak and liable to objections;—he supposes that leprosy is the cause of the black complexion and woolly hair of the negroes: it will be sufficient to state two of his arguments to prove how hard he is pushed to support this opinion, and how very absurdly, after all, he does support it: leprosy is accompanied, in some instances, with a black colour of the skin, therefore the black complexion of the negroes arises from this cause; but leprosy is also described, as giving rise to preternatural whiteness; hence this disease may also be considered as the cause of the singular complexion of the Albinos, or white negroes. His mode of accounting for the woolly hair of the Africans on this hypothesis, is equally unphilosophical: some medical writers look upon the *plica polonica,* as a species of leprosy, but the hair in the *plica polonica,* bears some slight resemblance to the hair of negroes, therefore the leprosy is the cause of two of the most distinguishing characters of this race, the blackness of their complexion and the crispature of their hair. This kind of reasoning is not unworthy of the man, who, in the same paper, could express his belief, that two women had become black, and got the features of negroes, by living with negro husbands. This, too, is an additional proof, that all negroes are lepers, as it puts it beyond a doubt that they are infectious. See *American Transactions,* vol. iv. p. 289, &c.

Classification of the varieties of the human complexion.

III. The different varieties of human complexion have been classed by several authors: the classification of Blumenbach, with some little alteration, is the most clear, methodical, and satisfactory. We shall give his classification of the more striking features, as well as of complexion, because, from the union and concomitancy of particular sets of features, with particular kinds of complexion, an argument will afterwards be drawn respecting the influence of climate on the human complexion.

According to this author, there are five varieties; the Caucasian, the Mongolean, the Malay, the Ethiopian, and the American.

Caucasian variety.

1. In the Caucasian variety, the skin is white, or rather brownish; the cheeks are red, and the hair of the different shades, from black to yellow, or red. The form of the head is nearly globular; the face oval and straight; the forehead expanded; the nose narrow at the base, and rather aquiline; the mouth small; the lower lip a little turned out, and the chin full and rounded. In this variety, Blumenbach includes all the Europeans except the Laplanders, the western Asiatics, including the Georgians, Caucasians, Persians, Arabians, &c. the northern Africans, and the Abyssinians. At first, he was disposed to arrange the Egyptians in this variety, but afterwards he altered his opinion, and placed them between the Circassian and Ethiopian. *Observations on some Egyptian Mummies, by* J. F. Blumenbach, *in the Philosophical Transactions for* 1794. The Gothic or German race, has also been taken out of the Caucasian variety by Dr Pritchard, and formed into a separate class, under the name of "*Constitutio Germanica aut Sanguinea.*" (*Disputatio inauguralis de hominum varietatibus.* Auct. J. C. Pritchard.) This has been done, rather on account of their difference in complexion than in features. They are characterized by blue eyes, flaxen hair, and very fair skin; their features are more rounded, and their eyes smaller than those of the nations which form the Caucasian variety. The Danes, Norwegians, and Icelanders, exhibit the peculiar features and complexion of the Gothic race, in their purest state.

Mongolian variety.

2. In the Mongolian variety, the colour is olive, the hair black, strong, and straight; seldom curled, or in great abundance: head of a square form; face broad and flattened; nose small and flat; eyes placed very obliquely; chin projecting slightly; the ears large, and the lips thick. This variety comprehends all the Asiatic nations to the east of the Ob and the Caspian, except the Malays; and according to Blumenbach, it also includes the Laplanders, Esquimaux, Samoieds, &c.; but Dumeril forms a separate variety of these, and the other tribes, who dwell near the north pole, under the name of the Hyperborean variety.

Malay variety.

3. The colour of the Malay variety is brown; their hair black, soft, curled, and abundant; their head is rather narrow; their nose full and broad towards the apex; their mouth large. The peninsula of Malacca, the islands near it, and those of the South Sea, are inhabited by this variety.

Ethiopian variety.

4. The Ethiopian variety have black skin and eyes; their hair is black and woolly; head narrow and compressed laterally; eyes prominent; their nose and lips, particularly the upper one, thick; and their chin receding. This variety comprehends all the Africans, except those which are placed under the Caucasian variety.

American variety.

5. The American variety have a red complexion; their hair resembles that of the Mongolian variety; their eyes are deep set; their nose rather flattened, and their face broad. All the inhabitants of the New World, except the Esquimaux, are comprehended in this variety.

The nature and colour of the hair seem closely con-

Complexion.

nected with the complexion; and, therefore, although in describing the varieties we have briefly noticed the difference in its colour, it may be proper to add a few particulars on this subject. In proportion to the thinness of the skin, and the fairness of the complexion, the hair is soft, fine, and of a white colour: this observation holds good not only in the varieties which have been described, but also in the Albinos. Next to them in fairness of complexion is the Gothic race, the *rutilæ comæ* of whom were a distinguishing characteristic, even in the time of the Romans. The Celtic tribes are not so fair as the Gothic, and their hair is darker and more inclined to curl; so that the observation which Tacitus makes respecting the Silures still applies to them, *Colorati vultus, torti crines.* But though the colour of the hair is evidently connected with the complexion, yet its tendency to curl does not appear to be so. The brown complexioned Celts have curled hair; the Mongolian and American varieties, of a much darker complexion, have hair of a darker colour, but long and straight. Among that portion of the Malay variety, which inhabits the South Sea islands, soft and curled hair is frequently met with.

The hair of the New Caledonians is crisped; that of the negroes woolly. The difference between these has been accurately marked by Forster. "The hair of the negroes," he says, "is not only frizzled, but each particular hair is found to be extremely thin, and proceeding from a root remarkably smaller than that observed in other human hair." This thinness he attributes partly to climate, but principally to the copiousness of perspiration not being checked by the use of oil. "The inhabitants of Otaheite," &c. he adds, "never have woolly hair, because they prevent too copious perspiration by the application of oil." This opinion, however, does not seem to be well-founded, since Winterbottom asserts that the custom of anointing with oil is universal among the Africans. Forster's *Observations made during a Voyage round the World*, p. 239. *Winterbottom*, vol. i. p. 192.

Colour of the eye.

The colour of the eye is also connected with the complexion. In the Africans, Professor Soemmering remarks, that the *tunica adnata*, or white of the eye, is not so resplendently white as in Europeans; but rather of a yellowish brown, something similar to what occurs in the jaundice. The iris in the negroes, in general, is of a very dark colour; but, according to Pegafeltu, the iris in the Congo negro is frequently of a bluish tinge; and it is worthy of remark, that, according to this author, these negroes have not the thick lips of the Nubians. The Gothic tribes are not more distinguished by their fair complexion than by their blue eyes (*cærulei oculi*); while the iris of the darker coloured Fin, according to Linnæus, is brown, and that of the still darker Laplander, black. The colour of the eyes also follows, in a great degree, in its changes, the variations produced by age in the complexion. Blumenbach informs us, that newly born children in Germany have generally blue eyes and light hair, both of which become gradually of a darker hue, as the complexion of the individual grows darker; and Ligon, in his "*True and Exact History of Barbadoes*," p. 52. says, that the children of the negroes there, when they are born, "have the sight of their eyes of a bluish colour, not unlike the eyes of a young kitten, but as they grow older they become black."

Albinos.

The most singular race of men in point of complexion, are the Albinos. It is doubtful whether Pliny referred to them under the name Leucæthiopes, as he merely gives the name; but from the manner of the term, it is probable he did. Tellezius, quoted by Ludolphus, in his *Ethiopic History*, (lib. i. cap. 14.), is among the first of modern writers who notices them: he says they were not uncommon in Abyssinia, where they were regarded with abhorrence, and their complexion was attributed to disease. Dampier and Wafer seem next to have noticed them in the isthmus of Darien. Knox, in his account of Ceylon, describes the Bedahs there as a kind of Albinos; but subsequent information respecting this island, though it proves this race to be very different from the other inhabitants, by no means confirms the account of Knox. Argensola, in *l'Histoire de la Conquete des Isles Moluques*, vol. i. p. 148. describes some of the inhabitants of these islands as Albinos, being as fair as Germans, with very weak eyes; and some of the older accounts of Chili and Florida, which mention the blue-eyed *cessares* of the former country, and the *acansas* of the latter, if they can be depended upon, would seem to prove that Albinos once existed in these parts of America. But this singular race of men is most commonly met with in Africa; and the African Albino has been most minutely examined and described.

Hawkins, in his *Travels in the Interior of Africa*, p. 116, describes the hair of the Albinos as red, or rather ashes coloured, sometimes approaching to yellow; and though soft, still preserving the woolly appearance of the negro. "The pupil of their eyes," he says, "is white." In the colony of Sierra Leone, Winterbottom saw a girl about nine years old, who had been born in Nova Scotia; her parents belonged to the Nova Scotian blacks, who were afterwards sent to that part of Africa. She had all the features of the negro; her hair was woolly, the colour of a dirty white; her skin differed from that of most Albinos, for though it equalled in whiteness the skin of a European, yet it had not that disagreeable appearance and texture which distinguish this singular race of people. She also differed from the generality of them in possessing stronger eyes, though the colour of them was somewhat between a red and light hazel. The same author saw another girl, of nearly the same age, born of black parents; her skin was of an unpleasant dead-looking white, pretty smooth, but beginning to assume a cracked appearance: this character of the skin is more distinct in the Albinos as they grow up; it then becomes remarkably coarse and wrinkled, dry and harsh to the touch, and marked with deep furrows. In this state of the skin, it is very susceptible to the action of the sun, which not only cracks it, but sometimes even occasions it to bleed: it is also very susceptible to the bites of insects.

The eyes of the Albinos are always deprived, in a greater or less degree, of their colouring matter, as well as the rete mucosum; the iris is sometimes red, and sometimes of a reddish brown colour; the pupil has the same tinge, and also the edges of the *tarsi*. When they are exposed to a strong light, they are continually winking.* In some instances, the sebaceous

* The eyes of the Albinos are also said to be entirely destitute of the *uvea*, and to have only the choroid coat very thin, and tinged of a pale red by discoloured blood: as it is known that the interior of the eye, when the embryo is about five weeks old, is covered with a blackish mucus, it is highly probable that this never exists, or is entirely destroyed in the Albinos; and thus the numerous blood vessels which nearly compose the iris and pupil, appear distinctly and unmixed.

Complexion. Albinos.

glands are very large and numerous. Winterbottom says, that the singularities which distinguish this variety of the human species, exist previously to birth: they never change afterwards, and are in some cases hereditary. † At Wankapong, this writer saw a young man, about 18 years old, whose father had been a white negro; his mother, three brothers, and two of his sisters, were black, but one sister was white like himself. None of these people whom Winterbottom saw, seemed to labour under any imbecility of intellect; but their corporeal strength, and their power of enduring fatigue, was inferior to that of other negroes. The same observation is made by Dampier, in his account of the Albinos of the isthmus of Darien, who, from his description, resemble those of Africa very much in the colour of their skin, hair, and eyes.

It was for a long time supposed that Albinos were confined to the East Indies, Africa, and America; and from their being found there, nearly under the same latitude, Buffon adopted the opinion, that "white was the primitive colour of nature, which, in certain circumstances, after having been varied by climate, by food, and by manners, to yellow, brown, and black, returns, but so greatly altered, that it has little or no resemblance to the original whiteness." This opinion, however, is not well-founded. Albinos, with exactly the negro cast of countenance, and the peculiar appearance of the eye, have been found in various parts of Europe; though the singularity is not nearly so striking in a white as in a black person. Professor Blumenbach says, that he has seen sixteen individuals resembling Leucæthiopians, born in various parts of Germany; and M. Buzzi, (*Opuscoli Scelti de Milan*, 1784), mentions a woman in that city who was the mother of seven sons, three of whom were Albinos. In 1803, a man died in Herefordshire, who was a complete Albino: he was rather below the middle stature; his hair was white and soft, and his eyes red. He was one of six children, all the rest of whom were quite exempt from this singularity.

Change of complexion by intermarriage.

A middle complexion is produced where children are born from parents of different races. If the offspring of the darkest African and the fairest European intermarry successively with Europeans, in the fourth generation they become white; when the circumstances are reversed, the result is reversed also. Along with the successive changes of complexion, is also produced a change in the nature and colour of the hair; though, in some instances, the woolly hair remains when the complexion has become nearly as fair as that of brown people in Europe. With regard to the offspring of Europeans and American Indians, the hair, according to Humboldt, does not indicate a mixture of the Indian blood, so clearly and certainly as the thinness of the beard, the smallness of the hands and feet, and a certain obliquity of the eyes. This offspring, to which the name of Mestizo is given, are distinguished by a colour almost pure white, and a skin of a particular transparency. Ulloa describes, in a more minute and exact manner, the signs which indicate the Mestizos. The most remarkable, according to him, is the lowness of the forehead, which often leaves but a small space between their hair and eyebrows; while, at the same time, the hair grows remarkably forward on their temples, extending to the lower part of the ear. Besides, he adds, the hair itself is harsh, lank, coarse, and very black; their nose very small, thin, with a little rising on the middle, from whence it forms a small curve, terminating in a point, bending towards the upper lip. These marks, besides some dark spots on the body, are so constant and invariable, as to make it very difficult to conceal the fallacy of their complexion; when, as it sometimes happens, it is so fine that they might otherwise pass for whites. (*Ulloa*, vol. i. p. 276.)

It does not, however, always happen that the offspring is the intermediate colour between that of the respective races to which the father and mother belong; it sometimes resembles one parent only; while, perhaps, in the second or third generation, the colour of the other parent makes its appearance.

White, *On the regular Gradation of Man*, mentions a negress who had twins by an Englishman; one was perfectly black, its hair was short, woolly, and curled; the other was white, with hair resembling that of an European: and Parsons, in the *Philosophical Transactions*, gives an account of a black man who married an Englishwoman; the child, the offspring of this marriage, was quite black. The same author gives another instance, still more remarkable: A black in Gray's Inn married a white woman, who bore him a daughter, resembling the mother in features, and as fair in all respects, except that the right buttock and thigh were as black as the fathers. (*Philosoph. Trans.* vol. i. p. 45.)

On the influence of climate in producing the varieties of complexion.

IV. The generally received opinion concerning the varieties of complexion which are found in the different races of man throughout the globe, is, that they are caused entirely by the influence of climate. Respecting the primary colour of man, the supporters of this opinion are not agreed. Buffon, as we have already noticed, thought that the primary colour was white, which, by difference of climate, food, and manners, was changed into yellow, brown, and black, and which manifested a strong tendency to return, notwithstanding the influence of these circumstances, in the Albinos. Mitchell, on the other hand, maintains, that the primitive colour of man was a medium between black and white, "from which primitive colour the Europeans degenerated as much on the one hand as the Africans did on the other; the Asiatics (unless, perhaps, where mixed with the whiter Europeans), with most of the Americans, retaining the primitive and original complexion." *Philosoph. Trans. abridged by Martyn*, vol. x. p. 948.

But whatever sentiments the advocates for the influence of climate on the colour of man entertain respecting the original complexion of the human race, they are all agreed concerning the nature and process of that influence. They contend, that climate having altered, in a slight degree, the complexion of the primitive inhabitants of the earth, their offspring, still exposed to the influence of the same cause, and being born of the acquired colour of their parents, produced a generation still varying in a greater degree from the primitive complexion; thus assuming, that the complexion caused by climate is transmitted to the offspring, by which means

† The hereditary tendency to this singularity of complexion, like other hereditary tendencies, sometimes remains evident for one or more generations. Parsons, in the *Philosophical Transactions*, vol. iv. p. 45, &c. mentions the case of a Negro woman, married to a man of her own colour, who brought forth a white child: afraid of the anger or jealousy of her husband, she wished to have concealed it from him, but he was neither angry nor surprised: he said that white children had often been born in his family; his father was of that complexion, while his grandfather and grandmother were blacks.

Complexion.

all the varieties we have enumerated have been formed. This opinion has numerous and able supporters; among whom Buffon, Blumenbach, Zimmerman, Winterbottom, Mitchell, and particularly Smith, may be mentioned. *

A contrary opinion is held by Boyle, Kames, Pritchard, and a few other writers. † They do not deny the influence of climate on the human complexion; but they contend, that if the varieties of the human race are accurately examined and compared with the climate in which they respectively live, the opinion which they controvert, will be found directly opposed by a number of well-established and decisive facts. They also maintain, that the operation of climate on the human complexion differs in some very marked and important points, from what are known to exist in the complexions of the great varieties of mankind. As the opinion of these writers is liable to be misrepresented, it may be proper to add, that they even admit that climate may and does influence the complexion of all the races which are placed under the different varieties; so that the Malay, the Mongolian, and the Ethiopian variety, may be more or less black; but, at the same time, they contend, that though climate will account for shades of difference in the complexion of these races, it will not account for the radical and distinctive complexion itself.

The opinion that climate alone will account for the various complexions of mankind, is very plausible, and supported by the well-known facts, that in Europe the complexion grows darker as the climate becomes warmer; that the complexion of the French is darker than that of the Germans, while the natives of the south of France and Germany are darker than those of the north; that the Italians and Spaniards are darker than the French, and the natives of the south of Italy and Spain darker than those in the north. The complexion also of the people of Africa and the East Indies is brought forward in support of this opinion; and from these, and similar facts, the broad and general conclusion is drawn, that the complexion varies in darkness as the heat of the climate increases; and that, therefore, climate alone has produced this variety.

But if it can be shewn that the exceptions to this general rule are very numerous; that people of dark complexions are found in the coldest climates; people of fair complexions in warm climates; people of the same complexion throughout a great diversity of climate; and races differing materially in complexion among the same people, this opinion must fall to the ground.

Dark complexions found in cold climates.

1. In the coldest climates of Europe, Asia, and America, we find races of a very dark complexion. The Laplanders have short, black, coarse hair; their skins are swarthy, and the irides of their eyes are black. According to Crantz, the Greenlanders have small black eyes; their body is dark grey all over; their face brown, or olive; and their hair coal-black. (Crantz's *Hist. of Greenland*, i. 132.) The complexion of the Samoieds and the other tribes who inhabit the north of Asia, and of the Esquimaux, is very similar to that of the Laplanders and Greenlanders. Thus we perceive that a dark complexion, which, according to the advocates for the opinion which we are considering, is the result of a warm climate, is found among those people who live in the coldest parts of the habitable world. This fact is so glaringly and decisively against their hypothesis, that to account for it, they are obliged to call in the operation of other causes, and to contend that extreme cold, especially when connected with poverty and filth, will produce the same complexion as extreme heat; but besides the objection to this modification of their original hypothesis, that it is evidently had recourse to, in order to obviate a pressing difficulty, and is not borne out by a sufficient number of facts, there is another objection still more fatal and unanswerable. If we examine the inhabitants in the north of Europe, we find the Norwegians fair complexioned, blue eyed, and with flaxen hair; we pass on to the northern extremity of Norway, and without experiencing any sensible change in the coldness of the climate, we suddenly and abruptly meet with the swarthy skins, and the black hair and eyes of the Laplander. The operation of extreme cold, therefore, to produce this darkness of complexion, cannot be allowed; and the unaided operation of the other two alleged causes, poverty and filth, will hardly be deemed sufficient to produce such essential and permanent characteristics of complexion.

Laplanders. Greenlanders. Norwegians.

Zimmerman has justly remarked, that, in considering the question of the cause of the different varieties in the human complexion, we should pay no attention to mere geographical latitude; since climate depends upon so many other circumstances, besides the distance of the country from the equator. This observation ought to be kept in mind in considering the following facts, which still farther prove, that in a comparatively cold climate dark complexioned people are found. In the narrative of a route from Chunargur to Ragamundry, in the Ellore Sircar, by Mr Blunt, he met with several tribes of mountaineers, whom he describes as having dark skins, lips thick and prominent, with high cheek bones. Although the country which they inhabited is in the latitude of 23° 28′ N. yet the climate must be very cold, from the following circumstances: At Shawpoor, on the 11th of February, the frost was very severe, and the trees had lost all their foliage. Mr Blunt informs us, that he ascended more than 300 yards, in perpendicular height, after he left Shawpoor, before he arrived at the mountaineers whom he describes; and when he requested of them information respecting the climate of their country, they told him, that they never experienced any hot wind; on the contrary, the frequent rains throughout the year rendered the air so cool, that during the night a covering was necessary, (*Asiatic Annual Register* for 1800, *Miscellaneous Tracts*, pp. 136, 148, &c.) Thus we perceive, that, in a comparatively cold climate, the complexion and features of the inhabitants greatly resembled those of the warmer countries of this part of Asia.

Indians.

South American Indians.

Humboldt's observations on the South American Indians, illustrate and confirm the same fact. If climate rendered the complexion of such of these Indians as live under the torrid zone, in the warm and sheltered vallies, of a dark hue, it ought also to render, or preserve fair, the complexion of such as inhabit the mountainous part of that country; for certainly, in point of climate, there must be as much difference between the heat of the valleys and of the mountains in South Ame-

* Buffon's *Nat. Hist* translated by Smellie, vol. iii. pp. 57—207; Blumenbach *de Gener. Human Variet*; Zimmerman's *Geographical History of Man*; Winterbottom's *Sierra Leone*, vol. i. p. 188, &c.; Mitchell's Paper in the *Phil. Trans.* already referred to; Smith's *Essay on the Causes of the Variety of Complexion and Figure in the Human Species.*

Complexion.

rica, as there is between the temperature of southern and northern Europe; and yet this author expressly assures us, "that the Indians of the torrid zone, who inhabit the most elevated plains of the Cordillera of the Andes, and those who, under the 45° of south latitude, live by fishing among the islands of the Archipelago of Chonos, have as coppery a complexion as those who, under a burning climate, cultivate bananas in the narrowest and deepest vallies of the equinoctial region." (*Political Essay on the Kingdom of New Spain*, i. 14, &c.) He adds, indeed, that the Indians of the mountains are clothed; but he never could observe, that those parts which were covered were less dark than those which were exposed to the air. The inhabitants, also, of Terra del Fuego, one of the coldest climates in the world, have dark complexions and hair.

Fair complexions found in hot climates.

2. Fair-complexioned races are found in hot climates. Ulloa informs us, that the heat of Guayaquil is greater than at Carthagena; and by experiment he ascertained the heat of the latter place to be greater than the heat of the hottest day at Paris; and yet in Guayaquil, "notwithstanding the heat of the climate, its natives are not tawny:" indeed, they are "so fresh coloured, and so finely featured, as justly to be styled the handsomest, both in the province of Quito, and even in all Peru." (*Ulloa*, i. 171.) "In the forests of Guiana, especially near the sources of the Orinoco, are several tribes of a whitish complexion, the Guiacas, the Guagaribs, and Arigues, of whom several robust individuals, exhibiting no symptom of the asthenical malady which characterises Albinos, have the appearance of true Mastigoes. Yet these tribes have never mingled with Europeans, and are surrounded with other tribes of a dark brown hue."* The inhabitants of Boroa, a tribe in the heart of Araucania, are white, and in their features and complexion very like Europeans.

South Americans.

Africans.

Even in Africa, darkness of complexion does not increase with the heat of the climate in all instances: the existence of comparatively fair races in this quarter of the globe is noticed by Ebn Hankal, an Arabian traveller of the tenth century, and has been confirmed by subsequent travellers. The following notices are from this author: In Bajeh, immediately bordering on the land of Abyssinia, is a race of people who have the same complexion as the Arabians. In Zingbar (Ethiopia) there is a race of white people, who bring from other places articles of food and clothing. But the most striking fact mentioned by this Arabian traveller, relates to a district which he calls Zouialah: This, he says, abounds in black slaves, but the inhabitants are of a brown complexion. In the eastern parts they are darker, and have light-coloured eyes; while some more remote have fair complexions, with blue eyes and reddish hair. One race of them has black eyes and black hair: These are said to be derived from the Arabs of the tribe of Ghirzaz. *The Oriental Geography of Ebn Hankal* translated by Sir William Ouseley, 1800, pp. 13, 14, 27.

Battal, an English traveller, observed, in south lat. 12°, a numerous camp of Negroes, of the Giagas or Gallas tribe, whom he describes as of a complexion much fairer than that of most other Negroes; and the complexion of the Foulahs, who live in 9° north latitude, is so fair, that some writers imagine them to be the Leucæthiopes of Ptolemy and Pliny. On the southwest, south, and south-east, Darfur, according to Browne, is bounded by two distinct races; one of which have woolly hair, and exhibit the true features of the Guinea Negro, while the other are of a reddish colour. The same author describes the people who inhabit the island near Assuan as black, but the people of the town are red coloured, like Nubians. The mountaineers of Harraza, and the inhabitants of Shulla, to the south of Darfur, are also red, (Browne's *Travels*, p. 165.) In some of these instances, the difference of complexion may have risen from the intermixture of races; but this observation will certainly not apply to all the cases. It may also be said, that there are two distinct races near Darfur, the Moors or Arabians, and Negroes, and that the fair complexion is entirely confined to the former. This observation will be considered, when we come to investigate the effects of a change of climate on the human complexion, when it will probably appear, that the difficulty in the way of the hypothesis we are combating is equally great, whether such marked differences of complexion are found among the aborigines, or among two distinct races, one of whom has been subjected for centuries to the operation of the same climate, which is said to have produced the darker complexion of the other.

The same complexion found in varieties of climate.

3. The same complexion is found over immense tracts of country, comprehending all possible varieties of climate. The most striking and decisive instance of this, is on the continent of America; all the inhabitants of which, with the exception of the Esquimaux, exhibit the copper-coloured skin, and the long and strait black hair. "Over a million and a half of square leagues," (observes Humboldt,) "from the Terra del Fuego Islands to the river St Lawrence and Beering's Straits, we are struck at the first glance with the general resemblance in the features of the inhabitants." (*Humboldt*, i. 144.) The same remark is made by Forster, who accompanied Captain Cook in one of his voyages round the world. (*Gottingen Magazin*, 1783, p. 929.) There are, no doubt, shades of difference in the complexions, and even some exceptions to the general remark, of a more decisive character: but these exceptions rather make against, than in favour of the opinion, that the colour of the Americans is the effect of climate. Several of them have been already noticed. But the grand fact is sufficiently conclusive, that under all the diversity of climates which the continent of America contains, there is either no radical difference of complexion, or that difference is the reverse of what climate ought to produce.

New Hollanders and New Zealanders.

New Holland and New Zealand are instances of a similar nature, though on a less extensive scale, over the whole of the former island; even in the very cold climate of the southern parts, the complexion of its inhabitants is of a deep black, and their hair is curled like that of negroes. New Zealand stretches from 34° to 47° south latitude, but its inhabitants do not vary in their colour; they are equally tawny under the extreme cold of 47° south, as under the milder climate of the northern parts of the island. The complexion of the inhabitants of the southern division of these islands, and

* *Humboldt*, i. 144. This author mentions other facts, which prove, that colour, at least that of the Americans, does not depend on climate. The people of the Rio Negro are swarthier than those of the Lower Orinoco, and yet the banks of the first of these rivers enjoy a much cooler climate than the more northern regions. The Mexicans are more swarthy than the Indians of Quito and New Granada, though the climate is exactly similar. "Under the 54° 10′ of north latitude, at Cloak Bay, in the midst of copper coloured Indians, with small long eyes, there is a tribe with large eyes, European features, and a skin less dark than that of our peasantry."

Complexion.

also of those of Van Diemen's Island, which lies in 45° south, is another striking proof, that a dark hue does not depend on the heat of the climate.

Different complexions found under the same physical latitudes.

4. Different complexions are found under the same physical latitude, and among the same people. Illustrations and proofs of this have already been given. The physical latitude in which the Norwegians, the Icelanders, the Fins, and the Laplanders live, scarcely differs, and yet their complexions, and the colour of their eyes and hair, are widely different. There is a great diversity of colour and features among the Morlachi, who inhabit Dalmatia. The inhabitants of Kotar, and of the plains of Seigu, and Knin, have fair blue eyes, broad face, and flat nose. Those of Duare and Vergoraz, on the contrary, have dark coloured hair, their face is long, their complexion tawny, and their stature tall. (Fortis' *Travels in Dalmatia*, p. 51.) M. Sauchez, who travelled among the Tartars in the southern provinces of Russia, describes a nation called the Kabendedski, as having countenances as white and fresh as any in Europe, with large black eyes. (Smellie's *Philos. of Nat. Hist.* ii. p. 167.) The inhabitants in the neighbourhood of the Cape of Good Hope differ in their complexions much more than in the nature of the climate under which they respectively live. The Caffres are black; the Booshuanas of a bronze colour; and the Hottentots, a light brown, or brownish yellow. In the island of Madagascar, there are three races, distinctly marked. The first are black, with frizzled hair, supposed to be the original inhabitants of the island. The second race inhabit the interior provinces; they are tawny, and have long hair like the Malays. The third race reside near Fort Daupliris, and on the west coast; they are supposed to be descended from some shipwrecked Arabs, and retain a resemblance to that nation, (Sonnerat's *Voyages to the East Indies and China* translated from the French, iii. p. 30.) People with the Negro complexion and features, are also found in the interior of the Philippine islands; and in Java, the Hindoo and Malay character may be clearly traced in the complexion and features of the two classes of inhabitants which are found in that island. In several of the Moluccas, is a race of men who are blacker than the rest, with woolly hair, inhabiting the interior hilly parts of the country. The shores of these islands are peopled by another nation, whose individuals are swarthy, with curled long hair. In the interior hilly parts of Formosa, the inhabitants are brown, frizzled haired, and broad faced, while the Chinese occupy the shores. Forster observes, that there are two great varieties of people in the South Seas; the one more fair, the other blacker, with their hair just beginning to be woolly and crisp. The first race inhabits Otaheite, and the Society Isles, the Marquesas, the Friendly Isles, Easter Island, and New Zealand; the second race peoples New Caledonia, Tanna, and the New Hebrides, especially Mallicollo. If we examine the relative situation and latitudes of these islands on a map, we shall be convinced, not only that darker complexioned people are found where the climate is comparatively colder, but that the same complexion is found under very different latitudes.

Dalmatians.

Caffres and Hottentots.

As, in several instances which have been given, especially under the last head, the difference of complexion may be supposed to have arisen from difference of race, and therefore by no means to prove the point at issue, we shall now proceed to consider the effects which have been produced by change of climate, where the complexion has been exposed to the operation of this cause for several generations.

Changes in the complexion by change of climate.

It may, however, be proper to premise one general remark: It would by no means follow, even if it could be proved that the complexion of the Caucasian, or fair-skinned variety, had been permanently and radically changed by long exposure to a warm climate, that this change was the effect, solely, or principally, of climate; intermarriage will produce the change to the greatest degree in which it is alleged to have been produced. Whereas, if cases can be brought forward, in which the primitive complexion of the variety has resisted the operation of change of climate for a great number of generations, it may fairly be inferred, that native differences of colour do not depend upon climate; and that, as they are not changed by a change of climate, they were not originally occasioned by climate. The cases which have been already given, of people with radical varieties of complexion and features existing together in the Philippine islands, in Madagascar, &c. ought, perhaps, to have been referred to that division of the subject which we are now about to discuss; but as there is no historical evidence, (though there is strong presumptive proof,) that the people of either of these varieties emigrated from a different climate to their present abode, it was thought more methodical to consider their cases under the last head; but however they are arranged, their bearing on the point at issue is equally direct and strong.

Complexion of the Colchi.

1. The case of the Colchi shall be first considered. Herodotus informs us, that, in his time, they were distinguished by the blackness of their complexion, and the crispature of their hair; and that, from these circumstances, the Egyptians regarded them as the descendants of part of the troops of Sesostris. This case is regarded by the advocates for the opinion that climate produces and changes complexion, as making very decidedly and strongly in their favour; no such people are now found in those regions, as Herodotus describes the Colchi to have been; therefore, they argue, that the blackness of their complexion, and the crispature of their hair, must have been destroyed by the influence of climate. The application of the general remark with which we introduced this part of our subject, would be a sufficient answer to this argument; since, during the course of 2000 years, intermarriages, and other causes by no means connected with climate, may fairly be supposed to have produced those changes which are attributed to climate. But the case of the Colchi, when properly considered, makes against, instead of for, the influence of climate: As, however, this view of the case cannot be put in its strongest light, unless we previously ascertain what were the complexion and features of the Egyptians (from whom the Colchi were supposed to be descended) in the time of Herodotus, a few observations must be premised on this point.

Complexion of the primitive Egyptians.

Volney maintains, that the primitive Egyptians were negroes. This opinion he draws from the present appearance of the Copts—from the features of the sphynx—and from the appearance of the mummies. Browne decidedly controverts this opinion: The Copts, he says, have no resemblance of the Negro features or form: Their complexion is a dusky brown, like that of the Arabs. But the argument drawn from the Copts, is of little value on either side of the question; for though they have intermixed less than most people with their conquerors, they cannot be regarded as pure. The an-

Complexion of the primitive Egyptians.

cient mummies, paintings, and statues, Browne adds, bear a strong resemblance to the modern Copts. This part of their argument will be afterwards considered: At present, we shall confine ourselves to this author's interpretation of the passage of Herodotus respecting the Colchi. The terms which the historian applies to the Colchi, μελαγχροες και ουλοτριχες, (Herodotus *Euterpe*, § 104.) Browne contends, are merely relative: "in the vernacular idioms of modern Europe, by the term a black man, is daily designated one of visibly darker complexion than ourselves." It is presumed, that this observation is contradicted by every person's experience, and therefore need not detain us; it is of more importance to seek for the real meaning of the terms used by Herodotus. If they do not designate the black complexion and crisped hair of the Negroes, it would be difficult to find terms in the Greek language to describe them. A few passages from other Greek authors will shew in what sense they are used: Strabo calls the Ethiopians μελανας και ουλοτριχας; and Aristobulus, who is quoted by this author, speaking of the Indians, says, they are not ουλοτριχας. Diodorus Siculus, describing the Ethiopians on the banks of the Nile, says they are μελανας, snub-nosed, τοις δε τριχωμασιν ουλοι; and, not to multiply instances in so plain a case, Aristotle, in his *Problems*, expressly asks, how it happens, that men ουλοτριχες are for the most part σιμωτεροι, (*Strabo*, lib. xv. p. 799. *Basil*, 1571. *Diodorus Siculus*, lib. iii. p. 103. Aristot. *Problem.* § 33. ques. 18.) We may therefore conclude, that the description given by Herodotus of the Colchi, designates men of black complexions and crisp hair; and that, in his time, the Egyptians were such.

The argument from the mummies, respecting the complexion and features of the primitive Egyptians, has been illustrated with great knowledge and acuteness by Professor Blumenbach: From an examination and comparison of different mummies, and of the artificial monuments found in Egypt, he infers, that there were three principal varieties in the national physiognomy of the ancient Egyptians; the Ethiopian cast; the one approaching to the Hindoo; and the mixed, partaking in a manner of both the former, (*Observations on some Egyptian Mummies*, Phil. Trans. for 1794.) The testimony of ancient historians, at least so far as regards the first two varieties, bears out the inference of Blumenbach. Besides the passage in Herodotus, we have the direct testimony of Diodorus Siculus, that the Ethiopians inhabited the islands in the Nile, and that they considered the Egyptians as one of their colonies. Subsequent historians represent the complexion of the Egyptians as less dark than it was in the time of Herodotus. Ammianus Marcellinus thus describes them: "Homines autem Egyptii plerique *subfusci* sunt et atrati," (*Ammian. Marcell.* lib. xxii. cap. 16.) From not adverting to the difference of the era of Herodotus and this author, Browne considers this passage as in favour of his opinion, that the Greek historian meant to describe the Colchi, as merely black and crisp haired in comparison with the Greeks; but, in the course of eight centuries, which had elapsed between the two authors, the intermixture of Persians, Greeks, and Romans, must have reduced the blackness of the Egyptians, as much as the difference between the terms used by them designates. The term which Ammianus Marcellinus applies to the Egyptians in a subsequent passage, "erubescunt," as it is applied to their moral character, and must therefore be taken in a figurative sense, is improperly considered by Browne as any proof of the truth of his opinion. But even before the time of Ammianus Marcellinus, the complexion of the Egyptians seems to have lost the darkness of the Ethiopian, and to have approached to the second variety mentioned by Blumenbach, viz. that of the Hindoo. Arrian describes the natives of the south of India as similar to the Ethiopians in the blackness of their complexion and hair, but without their crispature and form of nose; and he adds, the Indians who live nearer the north are liker the Egyptians. *

We may therefore conclude, that, though subsequently to the time of Herodotus, the complexion of the Egyptians had become less dark, and their hair less crisp. Yet in his time they greatly resembled the negroes in these respects; and consequently that the Colchi, whom he describes as resembling the Egyptians, and whom tradition represented as a colony from them, had black complexions and crisped hair. Let us now revert to the bearing of this fact on the question respecting the influence of climate.

In the first place, Herodotus expressly states, that the proof of the Egyptian descent of the Colchi, drawn from the complexion and hair, amounted to nothing, because there were other nations in that part of Asia with similar complexions and hair. From another passage in this historian we may infer, that this observation is to be taken in rather a qualified sense; by the expression "other nations," he evidently refers to the Eastern Ethiopians; but these he describes as differing from the Western or Libyan Ethiopians: his words are, "the Eastern Ethiopians have straight hair, those of Lybia have more crisped hair than that of all other men. (Lib. vii. § 70; and Lib. iii. §. 101.) It is however sufficiently evident from this historian, that people of such a dark complexion as to be called Eastern Ethiopians, inhabited that part of Asia, which was under the dominion of Darius the son of Hystaspes; and as there is no evidence that they were colonists, we must suppose they were the original inhabitants. The fact, therefore, of the non-existence now of a race of similar complexion and hair to the Colchi, is no proof of the influence of climate; since it cannot be maintained that the temperate climate, of which the Eastern Ethiopians were natives, would destroy the dark complexion of the Colchi. The testimony of Herodotus, therefore, to the existence of the Eastern Ethiopians in that part of Asia, must be considered as affording an additional proof, that there is no essential connection between radical and permanent darkness of complexion and extreme heat of climate; and the disappearance, both of the Eastern Ethiopians and the Colchi, must be ascribed to some other cause than the operation of climate.

In the second place, the Egyptian colony, from whom the Colchi were supposed to be descended, settled here in the time of Sesostris; that is, according to the most moderate computation, 1400 years before Christ: but Herodotus travelled for the purpose of collecting materials for his history about 440 years before Christ; so that the complexion of the Colchi had withstood the influence of the climate for nearly 1000 years; and if it withstood it so long, and the Colchi at the end of that period still retained the crispature of their hair, as well as the blackness of their complexion, we certainly are

* Arrian, *Ind.* p. 173. In his *Life of Alexander*, speaking of the Indians in general, he describes them as blacker than all men, except the Ethiopians.

justified in concluding, that the subsequent disappearance of these characteristics was owing not to the climate, but to other causes; but there are grounds for believing that the Egyptian characteristics of the Colchi continued unchanged long after the time of Herodotus. Bochart, in his *Sacred Geography*, cites passages from St Jerome and Sophronius, in which Colchis is called the second Ethiopia; and the last author, in his life of St Andrew, says that there were Ethiopians near the mouths of the Apsarus, and on the banks of the Phasis; that is, in the very country of the Colchi. (Bochart, *Geog. Sac.* lib. iv. cap. 31. p. 286.)

Black complexion extends farther north on the west side of Africa than on the east.

2. The black complexion extends much farther to the north, on the west side of Africa, than on the east: the inhabitants of Fezzan, in latitude 27° 48′ are black, whereas the Egyptians in the same latitude are brown or olive; on the east side of Africa, we must go to the latitude of 15° N. before we trace the line between the Arabs and the blacks. The Abyssinians are of a dark olive colour, with long hair; yet the adjoining people, and the people under the same latitude on the west side of Africa, are negroes. This difference of complexion and hair in the Abyssinians has generally been ascribed to their living under a more temperate climate than the negroes, though the latitude is the same; but their great resemblance to the Arabians, and the direct testimony of historians, proves that they are descended from that people; and, as Gibbon remarks, "the Arab cast of features and complexion which has continued 3400 years in the colony of Abyssinia, will justify the suspicion, that race as well as climate must have contributed to form the negroes of the adjacent and similar regions." (*Gibbon*, vii. 341.) If we trace the inhabitants of the east coast of Africa still farther to the south than Abyssinia, we shall detect, by their features and complexion, the Arabian conquerors; while the races, which they expelled, may be equally clearly traced in the districts into which they were compelled to remove. The difference between the Hottentots and Caffres has been already noticed:—the latter undoubtedly were originally natives of the warmer parts of Africa; and have been driven to the neighbourhood of the Cape by the pressure of the Arabians and other more powerful people. In the time of Vasco de Gama, about the end of the 15th century, the Caffres were found in Terra de Natal; and before that period they seem to have inhabited the coasts of Africa still farther to the north. (*Ancient Accounts of India and China by two Mahommedan Travellers* translated by Renaudot, p. 162—164.

3. Procopius mentions a race of people far within the desert of Lybia, not black-skinned like the Moors, but of very fair bodies and yellow hair: these have generally been supposed to be descendants of the Vandals; but had they been so, Procopius, who lived soon after the passage of the Vandals from Spain into Africa, would probably have mentioned their origin. Whatever, however, was the origin, or the time of their settlement, they were found by Dr Shaw, in the very spot where Procopius places them, on the mountains of Auress, with their yellow hair and their fair and ruddy complexion. (Procop. *Bell. Vand.* xi. c. 13. Shaw's *Travels*, p. 120.

4. Herodotus fixes the boundaries of the Libyans and Ethiopians near the Niger, about Cassona; and nearly the same line may yet be drawn in this part of Africa, between the fairer and darker complexioned natives. The Arabians, under the name of Moors, entered this part of Africa about the seventh century; and though in many places separated from the negroes, merely by the Senegal, and in other places inhabiting the very same regions, they are still distinct in complexion and features.

Complexion of the Huns.

5. The description which ancient writers give us of the Huns, evidently proves that they belonged to the Mongolian variety. Their original seat was an extensive tract of country, immediately on the north side of the great wall of China. About one hundred years after Christ, they emigrated in two great divisions, one of which settled in the fruitful plains of Sogdiana, on the eastern side of the Caspian. This division obtained the name of the *white* Huns, from the change in their complexions. This change Gibbon is disposed to attribute to the mildness of the climate in which they took up their abode; but as their emigration was from a colder to a comparatively warm climate, the change in their complexion and features must be ascribed rather to their intermixture with the inhabitants of the country in which they settled, probably with the Greeks of Sogdiana. †

Complexion of the inhabitants of the Andaman Isles.

6. Colonel Symes, in his embassy to Ava, landed on the Andaman Islands. The natives he describes as "a degenerate race of Negroes, with woolly hair, flat noses, and thick lips; their eyes are small and red, and their skins of a deep soot black." From this description it is evident that they resemble the natives of the interior parts of the Philippine islands; and we should have noticed the fact under a former head, had there not been proof of their unchanged complexion and features for nine centuries. The Mahommedan travellers of the ninth century, whose account has been published by Renaudot, describe the inhabitants of Andaman exactly as Colonel Symes does; "their complexion is black, their hair frizzled:" so that they not only differ radically from the inhabitants of the adjacent islands of Nicobar and the continent, but have undergone no alteration in this long period of time. (Symes' *Embassy to Ava*, p. 7. 4to. edit. *Asiatic Researches*, iv. 385. Renaudot, p. 4.)

Complexion of the Gipseys.

7. That singular race of people, the Gipseys, made their appearance in Hungary and Bohemia, according to Grellman, about the year 1417; and reached as far west as England, about a century afterwards. This author is of opinion that they came originally from the East Indies. Wherever they are found in Europe, they exhibit the same complexion, and colour of eyes and hair; nor, in the course of four centuries, do they appear to have lost, in the smallest degree, their original and primitive colour. (Grellman, *Hist. Versuch ueber die Liegenner.*) The same remark may be applied to the Jews; wherever they have preserved themselves unmixed, they exhibit a striking uniformity of complexion and features, in all the various coumtries of Asia, Africa, and Europe, in which they are found.

Complexion of the Dutch at the Cape of Good Hope.

8. Foster remarks, that "the Dutch who have been settled at the Cape of Good Hope, during an uninterrupted course of 120 years, have constantly remained fair, and similar to Europeans in every respect, though many of the Boors live almost in the same manner as their neighbours the Hottentots." (Foster's *Observations*, p. 271, 272.) And Chapman, in a narrative of a voyage to Cochinchina, informs us, that the aborigmes

† It is probable that the Mantchoo Tartars of China, who are represented as having fair and florid complexions, light blue eyes, and brown hair, are descended from the white Huns.

Complexion. Cochinchinese.

of this country, are called Mags, and inhabit the chain which separates it from Cambodia. They resemble the Caffres in features and complexion, whereas the present possessors, who came in the 15th century, retain the complexion and features of the Chinese, from whom they are sprung. (*Asiatic Annual Register for* 1801.) In the West Indies and America, Europeans and Negroes were introduced nearly about the same time; but they each retain their radical and permanent characteristics of features and complexion.

Complexion of the Goths, Celts, and Slavi.

9. Pinkerton, in his *Dissertation on the Goths and Scythians*, has proved, that the original inhabitants of Europe were Celts; that the Goths, coming from Asia, pressed there towards the west; and that the Slavi succeeded the Goths, and occupied the eastern parts of this quarter of the world. Each of these races was distinguished by peculiarity of features, complexion, and colour of eyes and hair, which they still retain in a greater degree than might have been expected, considering their intermixture: the *colorati vultus*,* and *torti crines* of the Celts, are much more common among their descendants, the Welsh, and the native Irish, than among the Gothic or Slavonic tribes. The characteristics of the Gothic race are frequently and strongly marked by the ancient historians; to the Germans, the epithets of *cœrulea lumina*, and *Flava cæsaries* are applied by Juvenal, (xiii. 164.) and *cœrulei oculi*, and *rutilæ coma*, by Tacitus; (German. iv.) and Manilius speaks of *flava Germania*, (Astron. lib. iv.) The Gauls, most of whom were a Gothic race, have applied to them, by Livy, the epithet *rutilatæ comæ*, (xxxviii. 16.) Virgil also describes their yellow hair, *aurea cæsaries*, (viii. 659.) and fair complexion, *lactea colla*, (Ib. 660.) and, in the time of Ammianus Marcellinus, they were distinguished by the same characteristics, *candidi pene Galli sunt omnes et rutili*, (lib. xvi. § 1. See also *Diod. Siculus* lib. v. Edit. Stephan, p. 212. and *Strabo*, lib. vii. p. 290, Edit. Caus.) The inhabitants of South Britain are described by Strabo as resembling the Gauls in complexion and eyes, but with hair less yellow; and the passage of Tacitus is well known, in which he infers the German origin of the Caledonians, on account of their *rutilæ comæ*, (*Strabo*, lib. iv. p. 194. Tacit. *Afric.* § 11.) The characteristic complexion, hair, and eyes, of the Goths, are still very evident in the Norwegians, Danes, and Icelanders, who have intermingled least with other tribes.† Forster is of opinion, that the blue eyes and red hair of the Gothic nations of Europe, are to be ascribed to the circumstances of their being "the most early inhabitants of the north, and therefore of their having had more time to become gradually fairer, than the greater part of their neighbouring European tribes;" (Forster, 273.) but this remark is not well founded; we have seen that blue eyes and red hair were characteristic of the Gauls, Germans, and Britons, in the time of the Romans; and they were also characteristic of other Gothic tribes in much more southern latitudes. About 270 years before Christ, a tribe of German Gauls founded the kingdom of Galatia in Asia Minor, and it is this tribe to whom Livy, in the passage already quoted, applies the epithet *rutilatæ comæ*. The description of the *Alani*, given by Ammianus Marcellinus, is a still more decisive proof that the fair complexion and flaxen hair of the Goths, are not attributable to the influence of a northern climate, but distinguished them in their native southern country. The Alani inhabited the plains between the Volga and the Tanais; and Ammianus Marcellinus says, they were almost all tall and fair, with hair inclining to yellow; Gibbon, indeed, ascribes the fairness of their complexion and hair to the mixture of Sarmatic and German blood; but we have the express testimony of Ammianus, Nicophorus Gregoras, and Xiphilin, that the Massagetæ and the Alani were the same people, and the Massagetæ were undoubtedly a pure Gothic tribe.‡

The Slavi, who came last into Europe, were distinguished by a brownish complexion, dark eyes, black or brown hair, and, in general, red bushy beards; and these marks they retain in the different climates of Poland, Bohemia, Russia, and Dalmatia.

Thus we perceive that the distinguishing complexions, hair and eyes, of the Celts, Goths, and Slavi, are, at the present time, nearly as well marked as they were in the time of the Romans, and that a change of climate has not essentially altered them. In traversing Europe, we pass from the Celtic tribes to the Gothic, and from the Gothic to the Slavoni, without experiencing any change of climate; and we find the comparatively dark-complexioned Celts and Slavi, in the Highlands of Scotland, and in the latitude of Petersburgh, while the blue-eyed, and comparatively fair-haired Goths, are found in the south of Germany. §

As, therefore, the dark-complexioned varieties of mankind are found near the Poles;—as people of the same complexion are found over the whole continent of America, under all its various climates; as there are numerous instances of comparative fairness of complexion under the heat of a burning climate; as radical differences of complexion are found in the same regions, and even among the same people; and as there are numerous instances where the original complexion has remained permanent, notwithstanding it has been exposed to a change of climate for centuries, it may fairly be inferred that the characteristic complexions of the different varieties of the human race are not the result of climate.

* That *colorati* means dark-complexion is evident from this epithet being applied by Virgil to the Ethiopians, (iv. 239. and to the Indians. Albinoranus also applies it to the latter, *coloratos postquam devicimus Indos*.—Eleg. xi. line 57.

† Volney says, travellers who go from Normandy to Denmark are struck with the resemblance between the natives of the two countries.

‡ Ammian. Marcell. xxxi. 2. Gibbon, iv. 373. Nicephorus Gregoras, lib. vi. *de alanis*; and Xiphinus in Hadriano. Pliny also reckons the Alani among the Scythic or Gothic nations.—Lib. iv. cap. 12. From the description which this author and Solinus, (who indeed is a mere abridger of Pliny,) gives of the Albani of Asiatic Scythia, Pinkerton infers that they were also a Gothic tribe, but as they are described as having *white* hair from their youth, reddish eyes, (*glauca oculorum acie, a pueritia statim canos*,) and as seeing better by night than by day, they were probably a species of Albinos. Besides, Pliny only says, there were some such people in Albania, not that all the inhabitants were of this description.—Pliny, *Nat. Hist.* lib. vii. cap. 2.

§ This general remark must be taken as liable to many exceptions, as, in every country in Europe, the intermixture of races has been very great and influential; but it is substantially true, that the Celtic, Gothic, and Slavonic races may still easily be recognized, and distinguished in Europe, whether they inhabit the warmer or colder latitudes: that climate will not account for the difference of their complexion since some of each tribe are found nearly in the same climate, and the extreme variation of climate in no case is great, and since before they settled in their present climates, they had the same distinguishing characteristics of complexion, hair and eyes, as they now possess.

Complexion. Difference between native and acquired complexion.

It is not meant to be denied that a burning climate will not render the complexion very dark; and that a climate of less extreme heat will not *bronze* the complexion of the fairest European; but there are some material points, in which the dark complexion of the Caucasian, or naturally fair-skinned variety of mankind, caused by climate, differs from the dark complexion of all the other varieties of the human race.

1. The offspring of the Caucasian variety is born fair;—the offspring of the other varieties is born of the respective complexion of their parents. Ulloa informs us, that the children born in Guayaquil of Spanish parents are very fair. (*Ulloa*, i. 171.) The same is the case in the West Indies. Long, in his History of Jamaica, expressly affirms, "That the children born in England have not, in general, lovelier or more transparent skins, than the offspring of white parents in Jamaica." But it may be urged, that this is not the case with respect to the other nations of the Caucasian variety, who have been settled in warm climates from time immemorial; and that the question ought to be decided by the Moors, Arabians, &c. Their children, however, are also born fair complexioned; as fair as the children of Europeans, who live under a cold climate. Russell informs us, that the inhabitants of the country round Aleppo are naturally of a fair complexion; and that women of condition, with proper care, preserve their fair complexion to the last. (Russell's *Aleppo*, i. 99.) The children of the Moors, according to Shaw, have the finest complexions of any nation whatsoever; and the testimony of Poiret is directly to the same effect: "The Moors are not naturally black, but are born fair; and when not exposed to the heat of the sun, remain fair during their lives. *Shaw*, p. 304; and Poiret's *Voyage en Barbarie*, i. 31.

Respecting the complexion of the Negro and Indian children, when first born, there appears to be some difference of opinion; but this difference will be found on examination to be of little moment, and to have arisen from some authors speaking of their complexion at the very moment of their birth, while others describe it, as appearing a few days afterwards. In fact, *all children*, immediately when born, have a reddish hue; and the children of Negroes and Indians resembling the children of Europeans in this respect, it has been inferred that they were born white. We should, therefore, endeavour to ascertain the complexion of Negro and Indian children, after the reddish hue is gone off, and before they could possibly be affected by the heat of the climate. Winterbottom informs us, that Negro children are nearly as fair as Europeans at their birth, and do not acquire their colour till *several days* have elapsed." (*Winterbottom*, i. 189.) And Ligon, in a passage in his account of Barbadoes already quoted, mentions that, when first born, the palms of their hands, and soles of their feet, are of a whitish colour. (*Ligon*, p. 52.) A friend of Mr Boyle's, who kept between 300 and 400 Negro slaves in the West Indies, informed him, that their children were of a reddish colour when born, like Europeans, but in a *few days* became black. (Boyle's *Works abridged by Shaw*, ii. 42.) And Andrew Pattell (whose travels are given in Purchas) says, that the children in Longo are born white, and change in *two days*. The dark complexion first appears round the nails, the nipples, and the private parts.

Humboldt affirms, that in Peru, Quito, on the coast of Caraccas, the banks of the Orinoco, and in Mexico, the children of Indians are never born white; but Gumilla, in a passage quoted by the translator of Humboldt, expressly asserts, that the Indian children, at their birth, are white, except a small spot on the waist; but in a few days acquire their natural colour. It is probable, that Humboldt speaks of them, not immediately on their birth, but when they had acquired this colour. (*Humboldt*, i. 146.) As, therefore, there seems no doubt of the fact, that the children of Negroes and Indians, whatever may be their colour immediately on their birth, become in *a very few days* of a dark colour, it may be regarded as a fair and indubitable inference, that this change is not produced by the climate. Those, indeed, who contend, that the children of Negroes are naturally fair, and acquire their dark complexion solely by the influence of the climate, wish to make out a case against their own hypothesis; for if climate could, in a very few years, or even months, render the fair born children of Negroes like their parents, the children of Europeans, born in Africa or the West Indies, should become equally black when they grow up; and we should not now be able to distinguish any difference between the Europeans and the Negroes in those countries. Besides, if this opinion were true, the fair born children of Negroes in Europe ought to continue fair during their lives, since the alleged cause of a change of complexion, a burning climate, did not exist.

2. Individuals belonging to the Caucasian variety that inhabit warm countries, preserve their native fairness of complexion, if they are not exposed to the influence of the climate; while there is a uniform black colour over all the parts of a negro's body. The women of Circassia, Arabia and Aleppo, and the Moorish women, we are informed by travellers, are very fair, not being exposed to the influence of the sun. (Russel and Poiret, in the passages already quoted; *Observations de Pierre Belon*, p. 199; *Voyage fait par ordre du Roi, dans la Palestine*, quoted by Buffon, and other authorities given by him, iii. 12.) On the contrary, every part of the body of a Negro or Indian is equally black. Soemmering asserts, that the cavity of the axilla, the inside of the thigh, and the *glans penis* are black; and even a small circle of the *conjunctiva* round the cornea is blackish, while the rest of the membrane has a yellowish brown tinge. Humboldt affirms, that "the Indian Caciques, who enjoy a certain degree of ease in their circumstances, and who remain clothed in the interior of their houses, have all the parts of their body (with the exception of the hollow of their hand and the sole of their foot) of the same brownish red, or coppery colour." And, in another place, he says, that "the Indians of the mountains (whom we have already noticed, as having as coppery a complexion as those in the vallies) are clothed;" and yet he never could observe, "that, in the same individual, those parts of the body, which were covered, were less dark, than those in contact with a warm and humid air." (*Humboldt*, i. 145. and 146.) Winterbottom makes the same remark respecting the Negroes, which Humboldt does respecting the Indians: "that the palms of their hands and the soles of their feet, are nearly as white as in Europeans, and continue so through life." (*Winterbottom*, i. 189.) This probably arises from the greater thickness of the cuticle in those parts, and is an argument against that membrane being the seat of colour in the dark-complexioned races.

But for the illustration of these points, it is not necessary to refer to the Negroes and Indians, as contrasted with the Caucasian race under a warm climate; in our own country, there are people naturally of a dark complexion, and people who are merely rendered

Difference between native and acquired complexion.

dark by the influence of the sun. The children of the former (if the parents are both dark-complexioned) assume the colour of their parents very soon after they are born (let them be ever so carefully protected from the sun); whereas, the children of parents merely tanned continue fair, if not exposed to the sun. The skin of persons in this country, naturally dark-complexioned, is nearly of the same colour all over their bodies; but the skin of tanned persons preserves its natural fairness in those parts which have not been exposed to the sun. The coldness of winter, or removal into a cold climate, has no visible or permanent effect on the complexion of people of this country, who are naturally dark; whereas, a dark complexion, merely acquired by exposure to the sun, even in the East or West Indies, is removed entirely, or in a great degree, by a cold climate. Indeed, the notorious fact, that in this and other northern countries of Europe, there are families of a naturally dark complexion, and families naturally fair skinned, but extremely liable to be tanned, proves that climate cannot be the sole cause of dark complexion; while the facts which we have stated, respecting the colour of the children of the Caucasian and other varieties, and respecting the different complexion of the Caucasian variety, according as the body is exposed to the sun, or kept covered, and the uniform colour of the Negro and Indian, illustrated as they are by what occurs among ourselves, clearly points out in what respects native complexion differs from acquired.

There are several other circumstances which point out the difference between native and acquired complexion, and which prove that the colour of the dark-complexioned varieties is not the effect of climate;—but on these we can merely touch.

The hue which Europeans assume is the same, though the tinge may be lighter, or darker, whether they settle in Africa, the East Indies, or South America. They do not become, like the natives of those countries, black, olive coloured, or copper coloured; their complexion merely resembles that of a tanned person in this country, only of a darker tinge. The Negroes that are settled in the West Indies, or America, do not assume the copper colour of the Indians, even though a milder climate may have some effect on the darkness of their complexions.

The children of Europeans, of Negroes, and of Indians, are all born in America of the same reddish hue; but in a few days, those of the Negro begin to assume the black complexion of their parents, those of the Indian the copper complexion, while those of the European either continue fair, if kept from the influence of the sun, or become tanned; not black like the Negro, or copper coloured like the Indian, if exposed to its influence.

Europeans who settle in Canada, or in the northern parts of America, where the climate resembles that of their native country, do not assume the complexion of the Indians, but continue fair like their ancestors. The same observation may be made respecting the Russians who are settled among the Mongolian variety, in those parts of the Russian empire in Asia, the climate of which resembles the middle or northern parts of European Russia. Indeed, the wide extent of country over which the Mongolian variety is spread, including the extreme cold of Lapland and the north of Asia, the mild temperature of the middle parts of that continent, and the warmth of the southern parts of China, is in itself a proof, that dark complexion does not arise either from the influence of heat or cold.

Lastly, Radical varieties of complexion are always accompanied with radical varieties of features. We do not find the olive colour of the Mongolian variety with the features of the Malay; nor the brown colour of the Malay with the features of the Mongolian; nor the black skin of the Ethiopian variety, or the red colour of the American, united with any set of features but those which characterise their respective varieties.

It, however, by no means follows, that the hypothesis of different races having been originally formed, must be adopted, because climate has been proved not adequate to the production of the radical varieties of complexion which are found among mankind. The conclusions which Dr Pritchard (*Dissert. Inaug. de Hom. Variet.* p. 119.) draws, are much more philosophical and consonant to all the facts which have been brought forward in this article.

1. That the natural constitution of man, as well as of animals, is modified by climate, manners, and other physical and moral causes.

2. That the effects thus produced are confined to one generation, and not transmitted to the offspring.

3. That man, as well as animals, has a propensity to form natural varieties; and that the diversities of mankind are proofs and examples of this propensity.

Lastly, That as this propensity will account for all the varieties of complexion and features found in the human race, it is unnecessary and unphilosophical to have recourse to the hypothesis of different species originally created, to account for the phenomenon. (W. S.)

COMPOSITE Ratios, in Music, are such as are multiples, or their terms are similar powers of some other ratio, as has been explained under our article Commensurable *Intervals.* Other ratios, forming by far the greater part of the whole number of musical ratios, are called prime ratios, and their corresponding intervals prime or incommensurable intervals: respecting which last it is proper to observe, that the *numbers* composing such prime ratios or prime intervals, are not *prime numbers,* except in a very few cases, but are most generally composite numbers, involving the primes 2, 3, and 5, in almost every form of combination. (ϱ)

COMPOSITION. See Criticism, Music, Painting, and Rhetoric.

COMPOST. See Agriculture.

COMPOSTELLA, or St Jago de Compostella, the *Brigantium* of the ancients, a city of Spain, and the capital of Gallicia, is situated on a hill upon the banks of the little river Soria. The streets are handsome but ill paved, and the largest of the four squares is tolerably elegant. The cathedral is a fine Gothic building, and has its interior fitted up with peculiar magnificence. It contains 23 chapels, of which that of St James is lighted only from the cupola, which is very lofty. It is adorned with the statue of St James made of massive gold, and two feet high. The front of the altar, belonging to the chapel of the relics, and the frame-work above it and the tabernacle, are all of massive silver; but the shrines for the relics are made of silver, gilt and adorned with a profusion of diamonds, precious stones, and pearls, and resting by silver supporters upon small slabs. On the right and left of the altar are two columns which support a canopy, the whole of which is covered with plates of silver. A thousand wax candles are lighted here every night; the effect of which is inexpressibly magnificent. The treasury of this ca-

Compound Stops.

thedral is very rich. The hospital for the reception of poor pilgrims is well endowed, and consists of two long square courts, surrounded with piazzas of freestone, supported by solid freestone pillars, and in the middle are beautiful fountains constantly playing.

The other ecclesiastical buildings are large and imposing; but the most interesting of them is the convent of St Martin, which is remarkable for its library, its cloister, and its regular architecture, which is of the Doric order. There are four parish churches in the town, and eight in the suburbs, besides six convents. There is also an university founded in 1522, four colleges, four hospitals, and an elegant asylum for young orphans. There are eight large mercantile houses in Compostella, which carry on a considerable trade. There is here a manufactory of silk stockings, three hat manufactories, one of paper, and three tan-yards. Compostella is the seat of an archbishop, and the principal place of residence of the famous order of the knights of St James, who possess 87 commanderies, and a revenue of upwards of 200,000 ducats of gold. The revenue of the archbishopric is about £25,000. Population 11,900. (π)

COMPOUND STOPS, in Music, is a term for those sets of ranges of pipes on an organ, whose notes are made to sound at the same time, by touching a single finger-key. Or, compound stops are such, wherein each finger-key acts upon two, three, four, or even five pipes of different pitches, and causes them all to sound together. The most common of these stops in our church organs are, the CORNET, the SESQUIALTER, and the MIXTURE, or furniture stops: (See those several articles.) These compound stops, when used in full pieces, with other stops that are not pitched or tuned to the actual note which they represent, in the diapason stop, (which is considered as a sort of standard,) but to the xiith, or xviith of such notes, (see LARIGOT, TIERCE, and TWELFTH stops), cannot fail of introducing a great number of actual discords even into the common chord, besides beating concords in plenty, with the notes of other finger-keys, as any one might readily satisfy himself, by writing down the values of the several notes thus sounded together, or even their artificial commas would be sufficient, taken from the first range, or Σ's, in the last column of Plate XXX. Vol. II.; or, these several notes might all be deliberately sounded together in succession, or in different pairs, on the single simple stop of an organ with an extended scale, like that of Mr Liston. From a series of experiments on such an instrument, when truly tuned, the reason might perhaps be discovered why the ear can tolerate such a mixture and jargon of discordant sounds as a full chord on an organ with compound stops presents; and whether it is merely by disregarding the discords, as it does any extraneous noise during a concert, as some have supposed. (ϱ)

COMPOUND CONCORDS, in Music, are such as are compounded of any two of the CONCORDANT *Elements*, (see that article,) or the simple or three least concords, 3rd, III. and 4th, or any of those again with one or more octaves, whether they form *original*, *doubled*, *tripled*, &c. concords; thus 3rd + III = V, 3rd + 4th = 6th, and III + 4th = VI; 3d + VIII = X, III + 2 VIII, &c.; V + VIII = XII, 6th + 2 VIII, &c. are all compound concords. (ϱ)

COMPOUND INTERVALS, in Music. Many writers, from contemplating some one of the many ways in which a particular interval may be compounded of, and consequently resolvable into, other smaller ones, have introduced this term, but which is in reality not a distinction, since every interval whatever may be *compounded* of one, two, or three others, by addition, addition and subtraction, or double subtraction. If one interval is successively added to form another, such should be called *double*, *triple*, *quadruple*, of that interval; as examples of the above, the double fourth or 7th = 24th; $\mathrm{T} = \mathrm{t} + \mathrm{c}$, $\mathrm{T} = \mathrm{t} + \mathrm{€} + \Sigma$, $\mathrm{T} = \mathfrak{S} + \mathrm{P} - \Sigma$, and $\mathrm{T} = \mathbb{T} - \mathrm{€} - \Sigma$, &c. ($\varrho$)

Comptonia || Conception.

COMPTONIA, a genus of plants of the class Monœcia, and order Triandria. See BOTANY, p. 322.

CONANTHERA, a genus of plants of the class Hexandria, and order Monogynia. See BOTANY, p. 194.

CONCEPTION, in pneumatology, is thus defined by Mr Stewart: "By conception I mean that power of the mind, which enables it to form a notion of an absent object of perception, or of a sensation which it has formerly felt." (*Elem. of the Philosophy of the Human Mind*, p. 132.) Again he says, p. 134, "The business of conception, according to the account I have given of it, is to present us with an exact transcript of what we have felt or perceived." According to this view of the subject, we ought to say, when we see an object with our eyes open, that we have a *perception* of it; when we shut our eyes, we have a *conception* of it.

We have no objection to this use of the word *conception*; but we are strongly inclined to suspect that it ought only to be considered as a modification of another faculty of the mind, and not as a distinct and original principle. In as far as conception relates to objects, or feelings which have already been presented to the mind, we cannot perceive in what it differs from the memory of past sensations, or perceptions. We should be glad to know the difference between a distinct *recollection* of past feelings or occurrences, and the conception of them. The object of memory is to store up in the mind the impressions which we have already received, and to bring them forth for use, as circumstances may require. When we have a distinct recollection of what we saw and felt yesterday, we may, in popular language, be said to have a clear conception, idea, or impression of it. But in all this we can see nothing but an ordinary exercise of memory: and we suspect that philosophers have created this new faculty of *conception* out of a figurative expression, which implies, at bottom, nothing more than a particular exercise of memory.

Mr Stewart confesses that conception is often confounded with memory. When a painter, for instance, makes a picture of an absent friend, he is said to paint from memory. But then it is said, "every act of memory includes an idea of the past; conception implies no idea of time whatever." *Philosophy of the Hum. Mind*, *ubi supra*. We apprehend there is no good reason for this distinction. The memory leaves out all idea of time, when it is conversant about mere relations, which are general, and have no reference to time. When the objects presented to our observation are of a singular nature, and such as rarely occur, time becomes an important accessary, and is recorded with a particularity corresponding to the rarity or supposed importance of the things. Hence when any thing remarkable occurs in the course of our lives, we commonly say, that we shall never forget the *time*. But nobody thinks of taking any account of time in considering those relations, which are treasured up in the memory, when they are of such a kind as occur every day, and fall in with the usual course of nature. In the same manner, when our thoughts are directed towards feelings or events necessarily connected with the *past*, and of such a nature that we are led to wish or fear their recurrence, in that case, *time* necessarily enters into our conceptions. But in thinking on the general laws of nature, and their various connections and relations, we never once think of *time*, though a moment's reflection would convince us that we are running over ideas which have already been presented to the mind.

Mr Stewart makes this distinction between conception and memory, that the former enables us to make our past sensations and perceptions, objects of thought; the latter recognises them as exact resemblances of what has been already felt or perceived. We confess that, in this instance, we cannot see the slightest grounds for a distinction. Does not every act of memory enable us to make our past sensations, or perceptions, objects of thought at the very moment that it recognises them as old acquaintances? Is it possible to recollect any thing without having an *idea* of it? We take the word *idea*, in this sense, to be perfectly synonymous with conception; and we maintain that no other power but that of recollection, or some modification of memory, is necessary to give us the idea, or conception of past sensations or perceptions. A man *remembers* that he was hurt, that he felt pain, that he had a leg amputated, that he was long in recovering; in all this, what use is there for the interposition of any other power than memory to recal the idea of his misfortune?

Conception is often confounded with imagination. Mr Stewart has very properly stated the distinction: he considers imagination to be that power which enables us to combine the parts of different conceptions, so as to form new wholes of our own creation. According to our view of the subject, the distinction is still more obvious. Conception, according to Mr Stewart, presents to the mind ideas already familiar to it; which we consider to be merely an act of memory, whose object is to give a faithful copy of the past, and which, in its simple exercise, is wholly uninfluenced by the will. Imagination, on the contrary, is memory, under the controul of the will, which, not satisfied with following the order prescribed by nature, or suggested by accident, selects the parts of different conceptions or objects of memory, to form a whole, more pleasing, more terrible, or more awful, than has ever been presented by nature. When we wish to represent the terrible, we seldom find in one object all the circumstances necessary to produce the full effect. We therefore bring together all the circumstances of terror *which our memories can recollect*, and we can conceive no other, in order to deepen the horror and heighten the effect.

We are aware that imagination is considered to depend chiefly on the association of ideas. But we are disposed to contend that even this *associating principle*, to which such wonderful effects are ascribed, has no claim whatever to be reckoned an original power of the mind. We conceive it to be also a modification of memory: and if it should be asked, how the recollection of one event suggests all its relations, and produces an unceasing flow of connected ideas, we answer, that it is merely the memory recording what has been presented to the mind, and running over that connected order, which has been exhibited in the course of nature, or in casual or artificial arrangements. Every event, and every object, is either the natural or the artificial sign of something connected with it; and memory may be called the recorded history of these relations. It places before the mind what has been felt or perceived; and it is as natural for it to recollect the order, and other circumstances under which objects were presented, as it is to recollect the objects themselves. And if we consider how almost infinite these relations may become, from time, or place, or circumstances, or feelings, we may easily conceive how the memory may expatiate over this boundless field, "and find no end in wandering mazes lost."

From the statement which we have given, it will appear, that we consider the ultimate principles of our nature as much fewer than have usually been represented: and we fear it is a proof of the little progress which has lately been made in the philosophy of mind, that whilst those facts in physical science, which were formerly considered as ultimate, are daily diminishing in number, in consequence of the extension of knowledge; an opposite process has taken place in the science of mind; and philosophers have shown a disposition to multiply, unnecessarily, the original principles of our nature. Every science is improved by the simplification of its principles; and this is an improvement which has not as yet been introduced into pneumatology.

The observations which have been made on this subject, are chiefly applicable to Mr Stewart's view of conception, which he represents as an exact transcript of past sensations or perceptions. But the term is used in a much more extensive sense by Dr Reid, who considers it as necessary in every operation of the mind. "It may be observed," says he, "that conception enters, as an ingredient, in every operation of the mind: our senses cannot give us the belief of any object without giving some conception of it at the same time." *Intell. Powers*, p. 358. So, then, to see an object with our eyes, or to handle it with our hands, is not sufficient to give us an idea of it: this mysterious power of conception must interpose, to introduce to the mind the ideas communicated through the organs of sense. The senses are the doors by which the visitors are admitted; conception is the gentleman usher who introduces them to the presence. Are we then to consider conception as the connecting link between the senses and the mind? We must first see the shadow of a proof in support of such an opinion. The senses are quite sufficient to do their own office; though the imperfection of philosophy has been woefully exposed in attempting to explain the manner in which they accomplish their end.

Conception, considered as an original power of the mind, must mean the power of forming conceptions, notions, or ideas. Dr Reid himself confesses, that these words are used synonymously, *Intellect. Powers*, chap. 1. On the same principle, then, we might say, that the power of forming ideas, is an original power of the mind. But it is perfectly evident, that some of our ideas may be traced to one simple faculty, whilst others result from the combined operation of different powers: and is not this the true origin of our conceptions, taking the word in the extensive sense in which Dr Reid employs it? They can be traced to simple powers of the mind, or to their combinations: and whatever idea, or conception, arises from the exercise of one or more of our faculties, is, *ipso facto*, presented to the mind, without requiring the intervention of any power distinct from those in which it originates.

It has been assumed as a maxim in philosophy, that *whatever we can conceive is possible*: but this has been strenuously contested by Dr Reid, *Intellect. Powers*, p. 400. According to Mr Stewart's doctrine on conception, however, the proposition is self-evident. If it gives us an exact transcript of what we have perceived or felt, then, whatever we can conceive is possible; for its possibility has been demonstrated by its having al-

Conception.

ready been an object of our perceptions or sensations. And even taking conception in its most extensive signification, as the power which gives us the knowledge of every combination which the mind can form, we apprehend that even in this sense whatever we can conceive is possible. In the most extravagant workings of the imagination, though the combinations may be new, yet they are all composed of old materials, and though the images may be incongruous, they are not contradictory; however absurd, therefore, they may be, yet they are not impossible. The meaning of the proposition, contested by Dr Reid, evidently is, that *whatever we can conceive to be possible, is possible.* This explanation would obviate his objection, drawn from the *Reductio ad absurdum,* in mathematical propositions; in which, he says, we are required to conceive things that are impossible, in order to prove them to be so. We can conceive *what is meant* when it is affirmed, that three and three make seven, but we cannot for a moment conceive it to be possible. But then, says Dr Reid, what one man judges to be possible, another judges to be impossible; the maxim therefore in this sense cannot be true. But whenever two men are found to differ respecting the possibility or impossibility of any proposition, fact, conception, &c. it will probably be found that their conceptions are both correct, *according to the view which they have taken of the subject.* From limited views, or false principles, a man may conceive a very obvious truth to be impossible: according to his conception of the subject, he is perfectly right: it cannot be possible, on the principles which he has assumed: but remove his prejudices, and correct the errors of his judgment, and then his conceptions will keep pace with the enlargement of his knowledge, and he will see the truth of what he before conceived to be impossible.

We have ventured, in this article, to call in question the opinions of some eminent philosophers, whose abilities we highly respect, and whose labours we duly appreciate. They have done much more, indeed, than could have been reasonably expected, in the infancy of pneumatology: their ingenious observations, and valuable facts, must facilitate the investigations of future enquirers: and much certainly yet remains to be done. We conceive the science of pneumatology to be, at present, much in the same state in which chemistry was, in the days of the alchymists, when false but ingenious theories stimulated enquiry, and evolved facts, which a more accurate method of philosophizing has reduced to the regularity of science. (*g*)

CONCEPTION, Concepcion, or Penco, is the chief city of Chili, in South America, and principal place of a province and corregiomento of the same name, was founded by Pedro de Valdivia, in the year 1550. The old city was situated on a gentle declivity, at the mouth of the river St Pierre, and its houses and public buildings, with the exception of the college of the Jesuits, were equally mean and insignificant. In the year 1751, it was completely destroyed by an earthquake, and the greater part of it swallowed up by the sea. About three leagues from the old town, and a quarter of a league from the river Biobio, a spot was chosen, in 1763, for the scite of the new city. In order to guard against the effects of earthquakes, the town was built so as to occupy a great extent of ground, and the houses were erected only of one story. Owing to the low state of commerce, the houses of the most wealthy inhabitants are destitute of furniture, and almost all the artificers in the town are foreigners. The harbour of Conception, which is in the form of a horse shoe, and which is called by the Spaniards Herradura, is five leagues from the town, with which it communicates by means of light vessels by the river Andaliers. The town of Conception carries on a considerable trade with Peru, by means of ten or twelve vessels, and the principal articles of commerce are hides, tallow, dried beef, and wheat, besides the flour and biscuit which it furnishes to French vessels on their way to Peru. In return for these it receives from Lima, tobacco, sugar, and some articles of European manufacture. The inhabitants also carry on a considerable trade with the Puelches, a savage and independent tribe, who inhabit the Cordilleras. The quantity of gold annually found in the diocese of Conception is valued at 200,000 piastres. Population, 13,000. West Long. 73° 4′ 45″, and South Lat. 36° 49′ 10″.

Conception, Concert Pitch.

For a fuller account of this town, and the bay of Conception, see Ulloa's *Voyage to South America,* vol. ii. chap. v. vi. p. 234, Eng. edit. 1807; La Perouse's *Voyage round the World,* vol. i.; Alcedo's *Geograph. Dictionary,* vol. i. p. 500.; and the article Chili, vol. vi. p. 194. (τ)

CONCEPTION. See Midwifery.

CONCERT Pitch, in Music, is that particular pitch, or degree of acuteness, of the several notes which is used in the best concerts of this period. This *pitch* is entirely a matter of convention, or agreement, among musicians, there being nothing in the nature of sounds that can fix or determine the pitch of any particular note of the scale; nevertheless, any one of these being assumed or given, the principles of harmonics, and rules of tuning thence derived, will enable the practical musician, or tuner, therefrom to derive all the other notes of the scale.

With singers, where no instrumental accompaniments are used, it is common to use a Pitch-Pipe, almost similar to a stopped organ pipe, having the handle of its piston, or plug, graduated, or marked with the distances to which it should be drawn out, to sound each of the twelve half notes in the scale, or more, if wanted; and, before beginning any piece of music, the pipe is set to the key-note of the tune, or piece, and sounded. This is called pitching the tune, anthem, glee, &c.

Performers on stringed instruments, as violins, violoncellos, &c. commonly (when there is no organ or piano forte present) use a Tuning-Fork for pitching the note A, (because they have no string for C,) but tuners of keyed-instruments, harps, &c. and some singers, use a C tuning-fork, this being the note which is considered as the fundamental key-note, or lowest of the twelve notes in the scale. The particular C (among its various octaves) that is generally sounded by large tuning-forks, is that on which the tenor-cliff is placed, called the tenor-cliff C, and answers to a leger line above the bass stave, and the same below the treble stave, in written or printed music: it is C-*sol-fa-ut* of the Guidonian gamut, $\bar{c}$ of the German tablature, and C of the middle septave, according to Earl Stanhope.

The most modern musical writers seem agreed, that the present *pitch* of the last-mentioned note is such, that it excites 240 complete or double vibrations in the air, that is, backwards and forwards, in one second of time, at or near a mean state of the barometer at 30 inches, and the thermometer at 60°, the latter in particular; and all the various tables of beats of tempered systems, which have been published in the *Philosophical Magazine* by Mr Farey and Mr Smyth, and those which will be given in our work, under the names of the inventors of the systems, &c. are adapted to this pitch of the tenor-cliff C, and will only apply to instruments of that pitch.

In our article ACOUSTICS, vol. i. p. 115, we have given a simple and useful theorem, that may also be thus expressed, viz. $N = \left(\sqrt{\frac{96.5t}{w}} \div L\right)$, for finding the number of complete vibrations made by any note in one second of time; which we shall here illustrate, by the calculation of an example at length, by logarithms, so arranged, as to serve as a *formula* for all similar operations, of an experiment that we once made on a C tuning-fork, or rather, on the vibrations of a brass-wire tuned unison therewith, the wire taken from a coil, of which (58.4 inches in length weighed .0073 lb. avoirdupois) 1 inch weighed .000125 lb. (w) One end, of a sufficient length, of this wire was fixed to the top peg of a vertical monochord, or SONOMETER, hanging over a pretty sharp steel edge below the peg, and to the other end of this wire a sort of scale-dish, for receiving weights (decimals of the lb. of 7000 grains) was attached; and a 10 lb. weight being placed in the scale-dish, another moveable steel bridge on the monochord was set, and fixed so, that when, by tilting the monochord a little, or, rather, bringing it nearer to a vertical position than it before hung, by means of a strong hinge by which it was attached at the top to its frame and stand, this lower bridge cut off or limited such a part of the wire between it and the upper bridge, as gave a sound when struck, something lower than the fork under experiment. Other smaller weights were then added in the scale-dish, until the sound of this portion of the wire, 11.7 inches long (L) between the bridges, exactly agreed with the fork. The weights in the scale-dish, the weight of that dish and its apparatus, and the weight of the remaining length of the wire over and above 11.7 inches, being calculated, as above, and added together, gave 10.34 lb., extremely near (t), for the stretching weights; whence we have

Constant logarithm (of 96.5 inches)	= 1.9845273
Logarithm of the stretching weight (t), = 10.34 lb. . . .	= 1.0145205
	2.9990478
Logarithm of weight of an inch of the wire (w), = .000125 lb.	= 6.0969100
	2)6.9021378
	3.4510689
Logarithm of the length of vibrating wire (L), = 17.7 inches	= 1.0681859
Logarithm of the complete, or double vibrations, in 1″ (N) .	= 2.828830 = 241.48

Whence it appeared, that this tenor-cliff C fork gave 241.48, or very near $241\frac{1}{2}$ vibrations per 1″.

In calculating by this formula, it may be previously copied out, the lines being at proper distances, as above, ready to receive the numbers answering to t, w, and L, as they are determined in the course of the experiment; and it may not be amiss to observe respecting these, that *grains*, *ounces*, *grammes*, or any other weights, and their decimals, may be used, instead of pounds, provided t and w are both expressed in the same; and so *feet*, *lines*, *decimeters*, or any other measures, may be used instead of inches, provided the constant length, (96.5 inches, and its logarithm,) and the unit length of wire, as to the weight w, are both expressed in the same kind of measures. It can scarcely be necessary to subjoin, that the two first logarithms are added, the next subtracted from their sum, and the remainder halved, and from this the next is deducted, and the numbers answering to the remainder is taken from the Tables, as at the end. If it had been wished to reduce this fork to the proper standard of 240 vibrations, the apparatus remaining untouched for a few minutes, while the above calculations had been made. The following *formula* might, and may in all similar cases, be used for the necessary calculation of the proper, or corrected weight (t'), for such purpose, viz.

Constant logarithm (of 240^2) . . .	4.7604225
Logarithm of the former weight (t) = 10.34 lb.	1.0145205
	5.7749430
Logarithm of the former vibrations (N) = 241.48	2.3828812
	2
	4.7657624
Logarithm of the weight (t'), for 240 vibrations per 1″	1.0091806 = 10.214

Where the two first logarithms are added, the double of the third is deducted from their sum, and the number sought in the tables, that answers to this remainder. Whence it appears that 10.214 lb. ought to have been used, instead of 10.34 lb. to stretch the wire; and that the difference of these, or .126 lb. being taken out of the scale-dish, the wire would then sound the proper tenor-cliff C of *concert pitch*.

Then, a round file being provided, and the fork fixed in a vice, by slightly enlarging the size or depth of the bottom of the opening of the prongs of the fork, and repeatedly trying its sound with the wire, it might at length be brought to yield the proper number of 240 complete vibrations. If the fork had proved too flat, its pitch might be raised, by filing a small portion off the top of one or both of the prongs, so as to shorten them.

The above method, if repeated with care, and with different lengths of vibrating wire, and of weights, would very exactly adjust a tuning-fork, as exact, at least, as a *unison* could be judged of or adjusted by the ear, between the fork and the wire; and if, instead of trusting to this, a third sound from a wire or fork, a very little different from the unison intended to be adjusted, be provided, and the *beats* of the fork and wire, with this comparative sound, be made *equal* in a second or any other period, as Mr W. Nicholson recommends in his *Phil. Jour.* 8vo. i. p. 320, every desirable degree of accuracy may be obtained by this method, in the pitch of a 240 fork, as such might be called and marked.

If a fork or a pipe or major comma higher were wanted for tuning *organs* of Mr Liston's construction, as Mr Farey has shewn to be necessary, in the *Phil. Mag.* vol. xxxix. p. 420, the same must be adjusted to 243 vibrations for C′, and should be so marked: and if for Mr Loeschman's proposed enharmonic or perfect *piano* *forte*, (see *Phil. Mag.* xxxix. p. 423.) the forks should be adjusted to 237.032 for C'.

In the tuning of organs and piano-fortes by *tables of beats*, it will be improper to trust to a tuning-fork, or even to a standard pipe, perhaps, for adjusting C for tempered scales; but the second, third, or fourth of the methods laid down by Dr Robert Smith, in his *Harmonics*, 2d edit. p. 195, or his fifth method, p. 220. should some one or more of them be repeated, and the pipe slightly altered each time, if necessary, in order to bring it exactly to the proper pitch of C, or of C', according as may be wanted.

On euharmonic organs of Mr Liston's construction, there are a number of concords that are ready tuned, a comma sharpened or flattened, then after being re-tuned or examined, may be conveniently used in Dr Smith's second method: so those which are a schisma sharpened or flattened on such instruments, stand ready for proving the truth of the pitch, by counting the beats of such schisma-imperfect concords, and comparing them with a calculation previously made (see our article BEATS,) of the proper number per 1″, or any other period, as Mr Farey has shewn with respect to C E' ※; which fourth should beat 1.0836 times per second. See *Phil. Mag.* vol. xxxvii. p. 278.

The same gentleman has also derived a ready method of reducing an organ-pipe to 240 vibrations, by those who are furnished with a pocket-watch that beats or ticks 5 in a second, or 10 half-ticks, as those for experimental purposes always should be made to do, from considering the equal-beating system proposed some years ago by Earl Stanhope, (see STANHOPE's *Temperaments*,) viz. Tune the notes C, A ♭ and C, in the octave *below* the tenor-cliff C (CC being a true octave) such, that the minor sixth C A ♭ may beat *flat* 10 in a second, or agree exactly with the half-ticks of the watch, and then try the major third above, A ♭ C, and if this also agrees, but beats *sharp*, exactly with the ticks of the watch, the upper C vibrates just 240 times per 1″, as it should do. If the third beats ※ faster than the watch, the C's must each be lowered, until, by repeating the operation, they are found to agree; and the reverse, if it beats slower than the watch. With C, A ♭, and *f*, when C *f* is a perfect 11th, C A ♭ beats 10 ♭, and A ♭ *f* 10 ※: with C, E, and A ♭, when C E is perfect, C A ♭ is 10 ♭, and E A ♭ is 10 ※.

The complete table of the beats in the octave *above* the tenor-cliff C (240), in the system above mentioned, shews other *whole numbers* of beats *in a second* they may also be useful, with 10-beat, or with other watches; which beats, therefore, it may be right to set down here, viz. with C, E ♭, and G, when C G is perfect, or without beats, C E ♭ beats 15 *flat*, and E ♭ G beats 15 *sharp*; with C, E ♭, and C, C E ♭ is 15 , and E C is 15 ※; with C, E ♭, and B, when C B=V+III perfect (by help of G between them), C E , is 15 ♭, and E ♭ B is 30 ♭; with C, A ♭, and B, (C B as before) C A ♭ is 20 ♭, and A ♭ B is 30 ※; with C, A ♭, and *e*, when C *e* is a perfect Xth, CA ♭ is 20 ♭, and A ♭ *e* is 40 ♭; with C, E, D ♭, and *e*, when CE is a perfect III, and E *e* an octave, ED ♭ is 20 ♭, and D ♭ *e* is 20 ♭; with C, E ♭, B, and *e* ♭, when CB is V+III perfect, and CE ♭ is 15 ♭, E ♭ B is 30 ♭, and B *e* ♭ is 30 ※, then E ♭ *e* ♭ is a a true octave; with C, F, A ♭ and *f*, when CF is perfect, FA ♭ is 20 ♭, and A ♭ *f* is 20 ※, then F and *f* is a true VIII: and lastly, with C, A ♭, B, and *a* ♭, when CA ♭ is 20 ♭, A ♭ B is 30 ♭, and B *a* ♭ is 30 ※, then CB is V+III, and A ♭ *a* ♭ is VIII, both perfect; which many curious definite proportions between the beats (to the pitch 240) are of far more importance to the tuner, than any thing else belonging to this irregular douzeave, which Mr Farey has calculated, from his lordship's suggestions; and among them, proportions will be found, either in this or the inferior octaves, (where these beat only half as fast in succession as we descend,) that will watch the ticks of many watches, the same as those with 10 or 20 beats per second do a 10-beat watch, as above shewn: and it can scarcely happen with any watch, if the number of its beats or ticks in a second be calculated to decimals, when necessary, that the same, or some number of beats sufficiently near, and properly related as complements of VIII. or some other *perfect* interval,) will not be found, by a search into the several tables of beats that have been published, and if not, such can easily be contrived and calculated, by which the isochronism of the watch and the beats may be applied to examining, and in the most ready way correcting, the *pitch* of an organ. After, however, this mode has been applied, it will be right, if great accuracy is required, to try one of Dr Smith's methods above referred to, by way of check on the pitch. (*g*)

CONCHIUM, a genus of plants of the class Tetrandria, and order Monogynia. See HAKEA, BOTANY, p. 129.

CONCHOID. See CURVES.

CONCHOLOGY.

efinition. CONCHOLOGY is that branch of natural history which treats of shells, distributes them into genera and species, and describes the character and economy of the animals which inhabit them.

nportance of the ience vindicated. To some, the examination of this department of science has appeared useless, and unworthy to occupy the time and talent of an informed mind. Reasoning, with persons of this description, is seldom attended with any good effect. Ignorant of the advantages which have resulted to mankind, from an intimate acquaintance with natural objects, they overlook the steps by which they have been gained: and likewise seem to forget, that the examination of those objects, which an all-perfect Being has created, can never be degrading to man, who was sent into this world in order to examine, admire, and adore.

Besides, if we attend to the variety of forms which shells exhibit, and to the richness of their colouring, we will not be surprised that they have obtained a conspicuous place in public collections, and have attracted the notice of the curious observer. But to view shells merely as objects of beauty, without attending to the animals of which they form only a part, would be to overlook by far the most important branch of the science; and, like the florist, to take notice of colour and shape, and neglect to attend to those functions which, while they excite our astonishment, exhibit marks of design. The examination of the contained inhabitants, enlarges our knowledge of the laws of animal life, and teaches us that each shell, however insignificant it may seem to be, possesses faculties suited to the supply of its wants, and to the situation which it is destined to occupy.

History.

But we are not disposed to rest the claims of the science of conchology to public favour, altogether on the grounds which we have now stated. As objects of utility to man, shells deserve our notice. Many species supply his table with agreeable and nutritious dishes; others form most enticing baits for catching fish, or furnish materials for the manufacture of different kinds of dress. The pearl is prized as an ornament, and the Tyrian purple is deservedly held in estimation.

We must view shells likewise as the enemies of man, and entitled to his consideration. Some are deleterious to his constitution, while others defeat his plans. The Bernacle, by adhering to the bottom of ships, impedes their motion; and the Teredo pierces their planks, and destroys them.

When these circumstances are duly considered, the science of conchology will appear of importance, as it unfolds the history of objects of beauty, curiosity, and utility.

HISTORY OF CONCHOLOGY.

Ancients acquainted with conchology.

Of late years, the study of conchology has been pursued with eagerness by the most eminent naturalists. Under their auspices, the science has assumed a consistent and regular form. But let us not overlook the labours of the ancients. They may justly claim the merit of having first directed the mind to this subject, and we add to their praise, for having sketched the outlines of the plan, which has since been so successfully followed. In the enlightened ages of Greece and Rome natural history flourished, and the study of testaceous bodies occupied the attention of the man of science, and afforded recreation to the politician.

Aristotle, A. C. N. 322.

Aristotle flourished 322 years before the birth of Christ. His writings are precious monuments of his wisdom, and justly entitle him to rank as the father of natural history. He is the first who presented the world with a system of conchology. The outlines of his plan have been copied by succeeding conchologists. To him we are indebted for the orders, *univalves*, and *bivalves*. He likewise added a third order, in which he included the *turbinated shells*. Several of his genera are still retained, such as *Solen, Pinna, Nerita*, and *Pecten*. We grant, that he was acquainted with but few species, and that he even admitted as such many of the *opercula* of univalves; but when we consider the period during which he flourished, and the isolated nature of his labours, and compare these with the information in natural history which he possessed, we are astonished at his sagacity and wisdom.

Pliny, A. D. 80.

Pliny lived in times more favourable for the cultivation of science. The extensive shores of the Roman empire, the Mediterranean, and the Red Sea, presented a fine field to the enterprising conchologist. With all these advantages, little improvement was made by him in the science. His knowledge of species was more extensive than that of Aristotle, but his arrangement is unphilosophical, and his descriptions are unsatisfactory. To him, however, belonged some merit as a conchologist. He paid considerable attention to the form and external aspect of shells, in which he has been imitated by succeeding conchologists.

We must now pass over the dark ages which succeeded Roman greatness, in which science was degraded and ignorance deified. And when we arrive at the conclusion of the fifteenth century, we find little to interest or instruct us. Vincentius, in the year 1494, published his *Speculum Naturæ*. In this work he treats of the *Murex*, the *Purpeura*, and the *Ostrea*, but makes no attempt at arrangement. He borrows freely from his predecessors, Aristotle and Pliny, and supplies most liberally, from his own stores, notices of the superstitious absurdities of his day.

Vincentius, 1494.

Passing from the fifteenth to the sixteenth century, the conchological labours of three authors principally claim our notice. We here refer to the writings of Belon, Rondeletius, and Gesner. Belon, so famous for his travels in the East, and who was among the first of the learned men who travelled with the view of promoting science, published, in the year 1553, at Paris, an octavo volume, entitled, "*De Aquatilibus.*" To his descriptions of shells, he added a few tolerably faithful wooden representations.

Belon, 1553.

Two years after the work of Belon had made its appearance, Rondeletius, professor of physic at Montpelier, presented the world with his *Universa Aquatilium Historia*. His residence on the sea-coast afforded him an opportunity of examining the shells of the Mediterranean, an opportunity of which he seems to have availed himself. He has described and figured upwards of an hundred testacea.

Rondeletius, 1555.

Conrad Gesner, in the year 1558, published his work, *De Piscium et Aquatilium Animantium Historia*. Intimately acquainted with the knowledge of the ancients, and the observations of his immediate predecessors, Gesner, in this work, communicated much valuable information. His descriptions, in general, are ample, and his figures, though rude, are tolerably correct in the outline. He added several new species from the Indian and Arabian seas. To the threefold division of shells proposed by Aristotle, Gesner added a fourth, which he termed Anomola. Into this class he placed his genera of *Balani, Penicellæ marinæ, Tubuli marini*, and in company with these several crustaceous and molluscous animals.

Gesner, 1558.

During the seventeenth century, the science of conchology received many important additions. Johnston, in the year 1657, published his *Historia Naturalis de Exsanquinibus*. He employs in this work the classification of Aristotle, but divides the class *Turbinata* into two sections. The first section, *In Anfractum Torta*, includes the *Nautilus, Buccinum Murex;* and the second, *In Orbem Circumacta*, contains the *Trochi Neritæ*, and a few others.

Johnston, 1657.

In 1616, Fabius Columna published his *Aquatilium et Terrestrium aliquot Animalium aliarumque Naturalium rerum Observationes*. This work contains descriptions of several rare shells, with neat engravings. An edition of this work was published in 1675, by John Daniel Major, M. D. This naturalist, in imitation of Gesner, separated the genera *Lepas* and *Balanus* from the bivalves, and constituted them into a class by themselves, to which he gave the name of *Plurvalvia*.

Major, 1675.

Nehemiah Grew, in the year 1681, published his catalogue and description of the natural and artificial rarities belonging to the Royal Society of London, and preserved in Gresham College. We introduce this work, not so much with the view of mentioning that it was the earliest production of the kind which had appeared in an English dress, as of noticing the classification which he employed. To the divisions of shells termed univalves and bivalves, he added the class *Multivalves*, which Gesner had aimed at, and which Major had formed.

Grew, 1681.

We close our account of the testaceological writings of the seventeenth century, with noticing the labours of our countryman Lister, a name deservedly held in high estimation by all the lovers of science. Lister con-

Lister, 1685.

History.

menced his great work on shells in 1685, which he called *Historia sive synopsis methodica Conchyliorum.* The plates which accompanied this edition were 1057 in number, and contained precise descriptions of the shells, with a reference to the place from whence the specimens were brought. The plates vary in number and situation in other editions of this work, and appear to have been changed repeatedly by the author. The plates themselves were afterwards bequeathed to the University of Oxford, where they were republished, under the inspection of the Rev. William Huddesford. This gentleman added two *indices,* the one connected with Lister's own distribution, and the other with the Linnæan arrangement.

Lister distributed testaceous bodies as follows:

Lib. I. *De cochleis terrestribus.*

Pars. 1. De Buccinis et turbinibus terrestribus.

Lib. II. *De turbinibus et bivalvibus aquæ dulcis.*

Pars. 1. De turbinibus.

Pars. 2. De bivalvibus et fluviatilibus.

Lib. III. *De testaceis bivalvibus marinis, et conchis anatiferis.*

Pars. 1. De testaceis bivalvibus, imparibus testis.

Pars. 2. De testaceis bivalvibus, paribus testis.

Pars. 3. De testaceis multivalvibus.

Lib. IV. *De buccinis marinis, quibus etiam vermiculi dentalia et patellæ, numerantur.*

We conclude this account of Lister's labours, by stating, that he received the greatest assistance from his two daughters, Susannah and Ann Lister. To them was committed the charge of delineating and engraving the various objects; a task for which they appear to have been fully qualified, and whose names, say two eminent conchologists, " deserve to descend to posterity with their father's, and whose truly meritorious industry and ingenuity are patterns for their sex."

During the eighteenth century, the works which appeared on conchology were numerous and valuable. Collections of objects in natural history began to be formed on the continent, and in Britain, and vast sums were expended in bringing together the productions of nature. Naturalists were thus enabled to take more comprehensive views of objects, and to make more accurate arrangements.

Langius, 1722.

In the year 1722, Langius presented to the public a new system of conchology. To him we are indebted for having founded the distinctions of the genera on the aperture of univalves, and the hinge in bivalves. We shall here give the outlines of his system.

Pars. I. *Testacea Marina univalvia non turbinata.*

Classis 1. Testacea marina univalvia non turbinata, et in se non contorta.

Classis 2. Testacea marina univalvia, non turbinata, sed ita in se contorta, ut eorum spiræ non promeneant.

Pars. II. *Cochleæ marinæ, seu testacea marina univalvia turbinata.*

Classis 1. Cochleæ marinæ longæ, seu cochleæ marinæ ore admodum elongato et superius aperto.

Classis 2. Cochleæ canaliculatæ seu cochleæ marinæ ore elongato et superius in canaliculum abeunte.

Classis 3. Buccina seu cochleæ marinæ ore et mucrone simul elongatis primaque spira notabiliter ventricosa.

Classis 4. Strombi, seu cochleæ marinæ ore et mucrone simul insigniter elongatis, et prima spira notabiliter angustiore quam in buccinis.

Classis 5. Cochleæ marinæ ore admodum breve seu parvo, mucrone vero insigniter elongato.

Classis 6. Cochleæ marinæ breviores seu cochleæ marinæ ore et mucrone beviores, magisque contracto.

Pars. III. *Conchæ marinæ, id est testacea marina bivalvia quæ duabus constant valvis in cardine, articulatione quadam inter se conjunctis, ut commode claudi et aperiri queant.*

Classis 1. Conchæ æquilateræ, seu conchæ marinæ valvis equalibus ex utroque cardinis latere equalibus effusæ.

Classis 2. Conchæ inæquilateræ seu conchæ marinæ valvis equalibus ex utroque cardinis latere inæqualiter effusæ.

Classis 3. Conchæ anomolæ, seu conchæ marinæ valvis inæqualibus.

In perusing this system of Langius, it will be observed, that the author had bestowed considerable attention on testaceous bodies, and that he, in part, chalked out the course which Linnæus afterwards pursued.

In the year 1742, the splendid work of Gualteri made its appearance, containing 110 plates of shells. To this work Gualteri added a system of conchology composed by Tournefort, whose manuscripts, on this subject, had been presented to Gualteri, by Professor Targioni. This system exhibits the same force of intellect, the same penetration and discernment which characterise the other productions of that eminent naturalist. His generic characters are founded, in a great measure, on the structure of the hinge, and form of the mouth. His families are distinguished by a difference of shape. The old division of shells into univalves, bivalves, and multivalves, is retained, with this difference, that he gives the preference to the terms monotoma, ditomo, and polytomo. Shells in his system are thus arranged. Tournefort, 1742.

Classis I. Testacea Monotoma.

Familia 1. Testacea univalvia.
Fam. 2. Testacea spiralia.
Fam. 3. Testacea fistulosa.

Classis II. Testacea Ditoma.

Fam. 1. Testacea quæ arcte clauduntur.
Fam. 2. Testacea quæ semper hiant.

Classis III. Testacea Polytoma.

Fam. 1. Testacea quorum partes articulantur.
Fam. 2. Testacea quorum partes per cartilaginem connectuntur.

In the same year that Italy had he honour of publishing the work of Gualteri, France presented to the world the voluminous Treatise of D'Argenville. In this work, the ordinary division of shells into univalves, bivalves and multivalves, is employed; but the primary divisions depend on the animal being an inhabitant of the land, the fresh water, or the sea. The character of many of his genera correspond very nearly with those employed afterwards by Linnæus. The plates which accompany this work greatly surpass any thing of the kind which the public had seen before, being not only finely but accurately executed. D'Argenville, 1742.

In the year 1757, Adanson, in his *Histoire Naturelle du Senegal,* published a new system of conchology. His arrangement rests principally on circumstances connected with the structure and habits of the animals, to which he appears to have paid particular attention. His divisions are the following: Adanson, 1757.

History.

CLASSE I. LIMAÇONS.

SECT. I. *Limaçons Univalves.*

Adanson's arrangement.

Fam. 1. Les limaçons univalves qui n'ont ni yeux ni cornes.

Fam. 2. Les limaçons univalve qui ont deux cornes, et les yeux placés à leur racine et sur leur côte interne.

Fam. 3. Les limaçons univalves qui ont quatres cornes, dont les deux exterieurs portent les yeux sur le sommet.

Fam. 4. Les limaçons univalves qui ont deux cornes, et les yeux placés à leurs racines, et sur le côte externe, ou par derrière.

Fam. 5. Les limaçons univalves qui ont deux cornes et les yeux posés un peu au-dessus de leur racine, et sur leur côte externe.

SECT. II. *Limaçons Operculés.*

Fam. 1. Limaçons operculés qui ont deux cornes, avec un renflement, et qui portent les yeux ordinairment au-dessus de leur racine, et à leur côte externe.

Fam. 2. Limaçons opercules qui ont deux cornes sans renflement, et les yeux places à leur racine, et sur leur côte externe.

Fam. 3. Limaçons opercules, qui ont quatres cornes, dont les deux exterieures portent les yeux sur leur sommet.

CLASSE II. LES CONQUES BIVALVES.

Fam. 1. Les conques bivalve, qui ont les deux lobes du manteau separés, dans tout leur contour.

Fam. 2. Les conques bivalves dont les deux lobes du manteau forment trois ouvertures sans aucun tuyau.

Fam. 3. Les conques bivalves dont les deux lobes du manteau forment trois ouvertures dont deux prennent la figure d'un tuyau assez long.

CLASSE III. LES CONQUES MULTIVALVES.

Fam. 1. Les conques multivalves, dont aucune des pieces de la coquille ne prend la forme d'un tuyau.

Fam. 2. Les conques multivalves, dont une des pieces de la coquille prend la forme d'un tuyau qui enveloppe entierement toutes les autres.

Linnæus, 1766.

We come now to take a short view of the conchological labours of Linnæus. Considering his comprehensive genius, and the accurate views which he had with respect to arrangement, the world might have expected from his pen, a system freed from the imperfections which might have been observed in the productions of his predecessors, and at once obvious, simple, and convenient. That Linnæus fell far short of this, every one knows, who has paid any attention to the subject. Before the days of Linnæus, the secondary divisions of testaceous bodies were by far too numerous, and the characters of the genera and species vague and inaccurate. In attempting to avoid the former error, Linnæus greatly reduced all the ancient subdivisions, and even genera, and over-reached that useful simplicity which he had in view. But the greatest praise is due to this illustrious naturalist, for having employed, in the construction of his generic and specific characters, terms which were precise and applicable; and hence, his genera and species have acquired a stability which conchologists knew not before.

The primary divisions of Linnæus were such as had been in common use. He employed the divisions, univalves, and bivalves of Aristotle, and the plurivalves of Major, under the title of multivalves. And, in conformity with the general distribution of animals in his system, he placed the most complex shells, or the multivalves, at the beginning, and the univalves at the end. In the first arrangement of testaceous bodies, Linnæus only employed eight genera, *Cochlea, Nautilus, Cypræa, Haliotis, Patella, Dentalium, Concha*, and *Lepas*. In the twelfth edition, shells are distributed as follows:

History.

Linnæan arrangement.

I. MULTIVALVIA.

Gen. Chiton.	Gen. Pholas.
Lepas.	

II. BIVALVIA CONCHÆ.

Gen. Mya.	Gen. Spondylus.
Solen.	Chama.
Tellina.	Arca.
Cardium.	Ostrea.
Mactra.	Anomia.
Donax.	Mytilus.
Venus.	Pinna.

III. UNIVALVIA.

* *Spira regulari Cochlea.*

Gen. Argonauta.	Gen. Strombus.
Nautilus.	Murex.
Conus.	Trochus.
Cyprea.	Turbo.
Bulla.	Helix.
Voluta.	Nerita.
Buccinum.	Haliotis.

** *Absque spira regulari.*

Gen. Patella.	Gen. Teredo.
Dentalium.	Sabella.
Serpula.	

Remarks on the Linnæan arrangement.

This system, so much admired by the disciples of Linnæus, labours under several imperfections. Attending principally to the shells themselves, he, in a great measure, overlooked the contained inhabitant. Great pains are taken to give a description of a regularly shaped piece of carbonate of lime, while the animal in the description of the species is totally overlooked. We are aware, that, in the definition of the genera, the animals inhabiting each genus are referred to one or other of the molluscous genera. But these references are as absurd as they are useless. In vain will the student of nature look for the two tentacula and the fine fringed anus of the Dorris, in the species of the genus Chiton, which have no tentacula, and whose anus is placed at the posterior extremity; or for the four tentacula of the Limax, in the aquatic species of the Linnæan genera of Turbo and Helix. Linnæus states, as part of the character of his genus Limax: "*Foramen laterale dextrum. tentacula quatuor.*" Now, in all the aquatic species of Helices, only two tentacula can be observed; and in the reversed Turbines, the lateral pore is situated on the left side. Yet, the animals of those shells are referred to the genus Limax, by Linnæus himself! Innumerable instances of the same kind could be produced, to shew that the Linnæan arrange-

History.

ment nearly overlooks the contained animal, and is wholly occupied with the shell or covering, Linnæus never having paid attention to the animal. These remarks would not have been so applicable, had the peculiarities of the various species of animals, inhabiting shells, been noticed under the different molluscous genera, to which they are referred.

Many of the Linnæan genera contain species dissimilar in habit and economy to those with which they are joined. Thus, in the genera, Ostrea, Anomia, Nautilus, Turbo, Helix, and Serpula, shells very different in configuration are grouped together. This arose from his zeal to simplify, even when the subject did not admit of it.

We are at a loss to account for the licentiousness of the language employed by Linnæus, when treating of shells—language at which decency must revolt, and delicacy be offended; nor are we less astonished at succeeding authors, who have servilely copied his gross and impure allusions.

We would not wish, in this place, to be understood as condemning the Linnæan arrangement, because it is founded on the character of the shell. We only blame it for overlooking the contained animal. For no system of conchology, we believe, has ever been invented, which can lay claim to facility of practical application, where the characters are taken exclusively from the animal. If, in a correct arrangement of animals, the characters of the genera and species should be taken from obvious appearances, from parts which operate on the economy, and influence the habits of the animals, then must the shell be attended to, as affording the safest mark for a scientific distribution. The shell serves the animal as a support to its muscles and intestines, as a defence from its foes, and a protection against the vicissitudes of the element in which it resides. From the characters of the shell, therefore, all arrangement of testaceous bodies should be formed, and not from the contained animal, which, in many cases, presents itself to our notice in too imperfect a state, to admit of its being examined with a view to its classification.

O. F. Muller, 1776.

The zoological labours of O. F. Muller, have procured for him the reputation of one of the first naturalists of his age. In his distribution of shells, the characters of his genera are taken from the number and position of the tentacula of the animals in the univalves, and from the structure of the syphon in bivalves. In his Zoology of Denmark, we are presented with his latest views on the subject. He seems to have borrowed several of his characters from the works of Adanson, which we have already noticed. We will here give a short view of his system.

FAMILIA I. TESTACEA UNIVALVIA.

SECT. I. *Testacea univalvia, testa pervia.*

Muller's arrangement.

Gen. 1. *Echinus.* Testa crustacea, ano verticali, tentaculis simplicibus.
Gen. 2. *Spatagus.* Testa crustacca, ano infero, tentaculis penicillatis.
Gen. 3. *Dentalium.* Testa calcarea, testa rude, tentaculis nullis.

SECT. II. *Testacea univalvia, testa patula.*

Gen. 4. *Akera.* Apertura effusa, tentaculis nullis.
Gen. 5. *Argonauta.* Apertura profunda, tentaculis binis.
Gen. 6. *Bulla.* Apertura repanda, tentaculis binis setaceis, colliculo extrinsecus oculatis.
Gen. 7. *Buccinum.* Apertura ovata, tentaculis binis triangularibus, angulo intrinseco oculatis.
Gen. 8. *Carychium.* Apertura ovata, tentaculis binis truncatis conspicuis, angulo intrinseco oculatis.
Gen. 9. *Vertigo.* Apertura subquadrata, tentaculis binis sublinearibus, apice oculatis.
Gen. 10. *Turbo.* Apertura orbiculari, tentaculis binis setaceis, conspicuis, angulo extrinseco oculatis.
Gen. 11. *Helix.* Apertura lunari, tentaculis quatuor linearibus, apice oculatis.
Gen. 12. *Planorbis.* Apertura similunari, tentaculis binis setaceis, angulo intrinseco oculatis.
Gen. 13. *Ancylus.* Apertura totali, tentaculis binis truncatis, occultis, angulo extrinseco oculatis.
Gen. 14. *Patella.* Apertura totali, tentaculis binis setaceis, occulto angulo, extrinseco oculatis.
Gen. 15. *Haliotis.* Apertura repanda, poris pertusa.

SECT. III. *Testacea univalvia, testa operculata.*

Gen. 16. *Tritonium.* Libera, apertura canaliculata, tentaculis duobus linearibus, angulo extrinseco oculatis.
Gen. 17. *Trochus.* Libera, apertura sub-tetragona, tentaculis duobus setaceis, colliculo extrinseco oculatis.
Gen. 18. *Nerita.* Libera, apertura lunari, tentaculis duobus setaceis, angulo extrinseco oculatis.
Gen. 19. *Valvata.* Libera, apertura circinnata, tentaculis duobus setaceis, angulo postico oculatis.
Gen. 20. *Serpula.* Adnata, apertura orbiculari, tentaculis pinnatis.

FAMILIA II. TESTACEA BIVALVIA.

SECT. I. *Testacea bivalvia cardine dentata.*

Gen. 1. *Mya.* Testa altera extremitate hiante; cardine dente crasso solitario.
Gen. 2. *Solen.* Testa utraque extremitate hiante; cardine dente reflexo, sæpe gemino.
Gen. 3. *Tellina.* Siphone duplici murico; cardine dentibus utrinque tribus alternus.
Gen. 4. *Cardium.* Siphone duplici, cirrato, pedeque falciformi; cardine dentibus mediis alternis, remotis penetrantibus.
Gen. 5. *Venus.* Siphone duplici, cirrata, pedeque laminæformi, cardine dentibus tribus approximatis, lateralibus divergentibus.
Gen. 6. *Mactra.* Cardine dente medio complicato, adjacente foveola.
Gen. 7. *Donax.* Cardine dentibus duobus lateralique solitario.
Gen. 8. *Arca.* Cardine dentibus numerosis, alternis, penetrantibus.
Gen. 9. *Terebratula.* Branchiis circinnatis; cardine dentibus alterius uncinatis, valvula superiore deorsum perforata.

SECT. II. *Testacea bivalvia, cardine edentulo.*

Gen. 10. *Anomia.* Branchiis simplicibus; valvula inferiore perforata.
Gen. 11. *Ostrea.* Branchiis simplicibus, pede nullo; cardines fossula cava.
Gen. 12. *Pecten.* Branchiis cirratis, pede juxta auriculum cardine fossula ovata byssum emittens.
Gen. 13. *Mytilus.* Siphone duplici brevi; fossula lineare, byssum emittens.

FAMILIA III. TESTACEA MULTIVALVIA.

Gen. 1. *Chiton.* Valvulæ dorsales, tentacula nulla.
Gen. 2. *Lepas.* Valvulæ erectæ, tentacula bipartita.

History.

Gen. 3. *Pholas.* Valvulæ ad cardinem minores.

We are under the greatest obligations to this author, for the extension of our knowledge of the inhabitants of the testacea, and for the excellent figures of those which he has given.

Da Costa, 1776.

Da Costa, whose elements of conchology appeared in 1776, attempted a new arrangement of shells. Labouring to steer clear of the system of the Swedish naturalist, against whom he throws out several abusive strictures, he invented so many new terms, that his system never gained him much reputation. He was, however, well versed in the science of conchology.

To the modern naturalists of France, the science of conchology is under great obligations. They have studied the structure of the animals which inhabit shells with care, and have struck out several new views, to aid us in the formation of a natural system.

Bosc.

The work of L. A. Bosc, entitled *Histoire Naturelle des Coquilles, des Vers et des Crustacés*, contains a new arrangement of shells, differing somewhat from the Linnæan, and, in our opinion, preferable to that system. The following is a tabular view of his system.

Bosc's arrangement.

I. Coquilles. Multivalves.

1. *Les unes n'ont point de charnière.*

Genre Oscabrion. Genre Balanite.
Anatif.

2. *Les autres en ont une.*

Genre Pholade. Genre Anomie.
Taret. Calceole.
Fistulane.

II. Coquilles Bivalves.

1. *Elles sont on Inéquivalves.*

Genre Térébratule. Genre Avicule.
Cranie. Marteau.
Lingule. Vulselle.
Hyale. Huitre.
Orbicule. Gryptee.
Corbule. Plicatule
Pandore. Spondyle.
Houlette. Came.
Lime. Acarde.
Peigne. Radiolite.
Placune. Erodone.
Perne.

2. *Ou Equivalves.*

Genre Mye. Genre Mactre.
Glycemère. Crassatelle.
Solen. Trigonie.
Telline. Hiatelle.
Cyclade. Cucullée.
Venus. Arche.
Onguline. Nucule.
Donace. Mulette.
Carditte. Anodonte.
Hippope. Moule.
Tridacne. Pinne.
Bucarde.

III. Coquilles Univalves.

1. *Elles sont ou Uniloculairc.*

A. Celles qui sont en spirale.

History.

Bosc's arrangement.

* Sont ou en calotte.
Genre Patelle.
Oscane.
** Ou en tube.
Genre Vermiculaire.
Silicaire.
Arrosoir.

B. Celles qui sont sans spirale.
* Sont ou l'ouverture entière et sans canal a sa base.

Genre Carinaire. Genre Helice.
Haliotoide. Volvaire.
Sigaret. Bulle.
Stomate. Jacinthe.
Argonaute. Turritelle.
Concholepas. Cyclostome.
Nérite. Bulime.
Natice. Sabot.
Helicine. Toupie.

** Ou l'ouverture echancrée et canaliculée a sa base.

Genre Cerite. Genre Vis.
Pyrule. Pourpre.
Rocher. Volute.
Rostelaire. Ovule.
Strombe. Tarriere.
Buccin. Porcelaine.
Casque. Cone.

2. *Ou Multiloculaires.*

Genre Nautile. Genre Turrilite.
Orbulite. Baculite.
Ammonite. Spirule.
Planulite. Orthocèe.
Camerine. Hippurite.
Rotulite. Belemnite.

Bruguière.

The name of Bruguière will long be remembered. He had undertaken the helminthological department of the *Encyclopédie Methodique*, but a premature death deprived the world of his labours. He had finished the first volume of the article *Vers*, which does not go beyond the letter C. The figures which he subjoined are faithful representations. To Lamarck, we are indebted for several judicious observations on the system of Bruguière. Afterwards he published his *Systême des Animaux sans Vertebres*, in which a new arrangement of testaceous bodies is attempted. This system of Lamarck's was afterwards more fully illustrated by Latreille, in his *Tableau Methodique des Mollusques*, inserted in the 24th vol. of the *Nouveau Dictionnaire d'Histoire Naturelle*. The following short view of his system, will serve to illustrate the principles upon which it is formed. The animals which inhabit shells are described, along with the Linnæan mollusca, in his fifth class *Mollusques*, and in his sixth class, to which he has given the name of *Annelides*. This last class includes the annular mollusca of Linnæus, and a few of the inhabitants of testaceous bodies.

Lamarck.

Latreille, 1804.

Latreille's arrangement.

ORDRE PREMIER. CÉPHALÉS CEPHALA.

Une tete distincte et mobile; souvent des yeux.

Sect. I. *Cors nu.*

Genre Sigaret, *Sigaretus.*
Oscabrion, *Chiton.*

History. Latreille's arrangement.

SECT. II. *Cors Renfermé dans une Coquille.*

DIVISION 1. Coquille univalve, non spirale, recouvrant simplement l'animal.

Genre Patelle, *Patella.*
Fissurelle, *Fissurella.*
Emarginule, *Emarginula.*
Concholepas, *Concholepas.*
Crépidule, *Crepidula.*
Calyptrée, *Calyptræa.*

DIVISION 2. Coquille univalve, uniloculaire, spirivalve, engaînant ou contenant l'animal.

A. Ouverture échancrée ou canaliculée a sa base.

Genre Cône, *Conus.*
Porcelaine, *Cypræa.*
Ovule, *Ovula.*
Tarière, *Terebellum.*
Olive, *Oliva.*
Ancille, *Ancilla.*
Volute, *Voluta.*
Mitre, *Mitra.*
Colombelle, *Columbella.*
Marginelle, *Marginella.*
Cancellaire, *Cancellaria.*
Nasse, *Nassa.*
Pourpre, *Purpura.*
Buccin, *Buccinum.*
Eburne, *Eburna.*
Vis, *Terebra.*
Tonne, *Dolium.*
Harpe, *Harpa.*
Casque, *Cassis.*
Strombe, *Strombus.*
Ptérocère, *Pterocera.*
Rostellaire, *Rostellaria.*
Rocher, *Murex.*
Fuseau, *Fusus.*
Pyrule, *Pyrula.*
Fasciolaire, *Fasciolaria.*
Turbinelle, *Turbinellus.*
Pleurotome, *Pleurotoma.*
Clavatule, *Clavatula.*
Cérite, *Cerithium.*

B. Ouverture entière et sans canal a sa base.

Genre Toupie, *Trochus.*
Cadran, *Solarium.*
Sabot, *Turbo.*
Monodonte, *Monodonta.*
Cyclostome, *Cyclostoma.*
Scalaire, *Scalaria.*
Maillot, *Puppa.*
Turritelle, *Turritella.*
Janthine, *Janthina.*
Bulle, *Bulla.*
Bulime, *Bulimus.*
Agathine, *Achathina.*
Lymnée, *Lymnæa.*
Mélanie, *Melania.*
Pyramidelle, *Pyramidella.*
Auricule, *Auricula.*
Volvaire, *Volvaria.*
Ampullaire, *Ampullaria.*
Planorbe, *Planorbis.*
Hélice, *Helix.*

Genre Helicine, *Helicina.*
Nérite, *Nerita.*
Natice, *Natica.*
Testacelle, *Testacella.*
Stomate, *Stomatia.*
Haliotide, *Haliotis.*
Vermiculaire, *Vermicularia.*
Siliquaire, *Siliquaria.*
Arrosoir, *Penicellus.*
Carinaire, *Carinaria.*
Argonaute, *Argonauta.*

DIVISION 3. Coquille univalve, multiloculaire, engaînant ou renfermant l'animal.

Genre Nautile, *Nautilus.*
Orbulite, *Orbulites.*
Ammonite, *Ammonites.*
Planulite, *Planulites.*
Nummulite, *Nummulites.*
Spirule, *Spirula.*
Turrilite, *Turrilites.*
Baculite, *Baculites.*
Orthocère, *Orthocera.*
Hippurite, *Hippurites.*
Belemnite, *Belemnites.*

Genres incomplètement connus.

1. Coquille univalve uniloculaire.

Genre Planospirite, *Planospirites.*
Oscane, *Oscana.*

2. Coquille univalve sub-multiloculaire.

Genre Rotalite, *Rotalites.*

3. Coquille univalve sub-uniloculaire.

Genre Gyrogonite, *Gyrogonites.*

ORDRE SECOND. ACÉPHALÉS ACEPHALA.

Point de tête distincte; jamais d'yeux.

SECT. I. *Corps nu.*

SECT. II. *Cors renfermé dans une coquille.*

DIVISION 1. Coquille Equivalve.

Genre Pinne, *Pinna.*
Moule, *Mytilus.*
Modiole, *Modiola.*
Anodonte, *Anodonta.*

Corbule, *Corbula.*
Anomie, *Anomia.*
Cranie, *Crania.*
Terebratule, *Terebratula.*
Calceole, *Calceola.*
Hyale, *Hyalæa.*
Orbicule, *Orbicula.*
Lingule, *Lingula.*

In the sixth class of animals, according to Latreille, the Annelides, the remaining testaceous animals, are placed.

Division 2. Point Organes extérieurs.

Sect. II. *Animal se logeant dans un fourreau.*

Genre Dentale, *Dentalium.*
Spirorbe, *Spirorbis.*
Serpule, *Serpula.*
Vaginelle, *Vaginella.*
Speroglyphe, *Speroglyphus.*
Anatife, *Anatifa.*
Balane, *Balanus.*

Account of British Conchologists.

We have thus, in succession, given an abridged view of the most remarkable testaceological systems which have made their appearance; and we propose now to conclude the historical part of our observations, with a short sketch of the principal British naturalists who have elucidated the history of the shells which occur on our shores.

History.

Authors who have treated of British testaceology.

Merret, 1667.

In the year 1667, Merret published his *Pinax rerum Naturalium Britannicarum.* This work contains the first attempt to enumerate the productions of Britain. The *testacei,* as he terms shells, occupy little more than a page. The references are chiefly to Jonstone, Aldrovandus, and Gesner. His account of shells is destitute of system, and does not contain any description of species.

Lister, 1678.

Lister, in 1678, published his *Historia Animalium Angliæ,* and in the year 1681 an Appendix. This work contains a full account of the English shells known to that author. His descriptions in general are good, and the delineations of the shells correct.

Sibbald, 1684.

Sir Robert Sibbald, by whom the natural history of Scotland was very ably elucidated, published, in 1684, his *Scotia Illustrata.* In 1697, he published his *Auctarium Musæi Balfouriani,* and some other papers relative to conchology, in the *Philosophical Transactions.* His description of the shells of Scotland appears to us destitute of correct arrangement, generic characters, or specific distinctions.

Wallace, 1700.

Dr Wallace, in the year 1700, published an *Account of the Islands of Orkney.* In this work, he enumerates all the species which had come under his observation, amounting to nearly fifty, and has added a very good figure of the *Pecten distortus.*

We ought in this place, did our limits allow us, to notice the topographical labours of Leigh, in his *Natural History of Lancashire*—of Plot, in his *Natural History of Staffordshire and Oxfordshire*—of Morton, in his *Natural History of Northamptonshire.* In these works, the testacea are treated of in a very superficial manner. Nor can we say much more of the Hibernian historian, Dr Charles Smith, who, in his account of the counties of Waterford, Cork, and Kerry, has noticed a few of the more common species.

Pennant, 1777.

In 1777, Pennant completed his *British Zoology.* In this work, for the first time, were the animals of Britain classified according to the Linnean method of arrangement; and we believe, few works ever contributed so much to the extension and cultivation of British natural history. In the fourth volume of the above work, he enumerates 163 species of testacea, with concise descriptions, and many excellent figures. A new edition of this work has lately appeared under the inspection of his son, in which the recently discovered species have been added to those described in the former edition.

Da Costa, 1778.

In 1778, Da Costa published his *British Conchology.* His descriptions of the species are copious, and the work is embellished with 123 figures of rare shells. The arrangement of the shells in this work is according to the system which he had previously formed.

Microscopic shells.

In the year 1739, Plancus gave an account of the minute and rare shells discovered at Rimino, on the coast of the Adriatic sea. The shells which Plancus described were minute, and required the aid of the microscope for their examination. In this country, Mr Boys and Mr Walker turned their attention to these minute testacea, and discovered many new and curious species on the British shores. The labours of these inquirers were made known to the world in the year 1784, in a small quarto volume, entitled, *Testacea Minuta rariora nuperrime detecta in Arena Littoris Sandvicensis.* Many of these microscopic species are exceedingly beautiful, and appear to be widely distribu-

Boys and Walker, 1784.

History.

ted. We know, that many of the species are common to the south coast of England and the shores of the Zetland Islands. The microscopic species of shells have, since the labours of Boys and Walker, been very successfully examined by Mr Adams, in the third and fifth volumes of the *Transactions of the Linnean Society.*

Gordiner, 1788.

In the year 1788, Cordiner's *Remarkable Ruins and Romantic Prospects of North Britain,* appeared in numbers. Several plates of marine vermes are added, with descriptions. But these are too loose and inaccurate to be of any practical utility. Among the plates is a very good figure of Solen Minutus, and several Serpulæ.

Berkenhout, 1795.

Berkenhout published his *Synopsis of the Natural History of Great Britain and Ireland,* in the year 1795. This work contains a very correct list of the British testacea then discovered.

Pulteney, 1799.

In the year 1799, Dr Pulteney's catalogue of the shells of Dorsetshire appeared in Hutchinson's new and enlarged edition of the history of that country. This catalogue is very valuable, on account of the clear and concise specific characters attached to many of the species. The figures which he has given of many of the species described by him, are accurate and faithful representations of nature.

Donovan, 1799.

Mr Donovan, whose works on natural history have gained him so much reputation, commenced, in the year 1799, his work on *British Shells,* and in the year 1804, five volumes completed the plan. The work contains short descriptions of the different species, with well executed figures. The greater number of microscopic shells are excluded; and what seems a little surprising, no notice is taken of any of the species of the genus Chiton.

Montagu.

The conchological labours of Mr Montagu are entitled to the highest praise. His *Testacea Britannica* exhibits innumerable traces of perseverance, observation, and accuracy. In consequence of his situation on the sea-coast, he has had excellent opportunities of examining the animals of shells, which he has embraced. Two parts of his work appeared in 1803, and a supplement was published in 1808. The system which Mr Montagu follows is decidedly the Linnæan, on which he has endeavoured to make some improvements. He is the first British conchologist who has devoted much attention to the contained animals. The species described are upwards of 470 in number. The figures of the shells contained in thirty plates, are very just representations of nature, and do great credit to the female hand which executed them.

Maton and Rackett.

The descriptive catalogue of British Testacea, inserted in the 8th volume of the Linnæan Transactions, is a valuable addition to the British conchologist. It is the joint production of Dr Maton and the Rev. Thomas Rackett. The Linnæan arrangement and terminology are employed throughout. Many obscure species are here admirably elucidated, and the errors of preceding conchologists rectified.

Laskey.

1811

In the first volume of the Memoirs of the Wernerian Natural History Society, we are presented by Captain Laskey with a list of North British testacea, amounting to 271 species. Some of these are new. To the list is added a plate of well-executed figures.

TERMS USED IN CONCHOLOGY.

Terms used in conchology.

Explanation of Terms used in the Description of Univalves.

Cavity.

The *cavity* of univalves, or the space which the shell incloses, is, in a few species, divided into *chambers,* which have a pipe of communication, termed a *syphon.*

Terminology.

Base.

The *base* is considered as situated in the external orifice of the shell or *mouth,* and the opposite extremity of the shell is termed the *apex,* or *summit.* In the genus Spirorbis, the base is considered as that portion of the shell which adheres to rocks and sea-weeds. The mouth, in some species, possesses a testaceous *lid,* or *operculum.* This lid is generally attached to the organ of motion, and appears to be an instrument of defence. When the animal withdraws itself into the shell, the lid closes the orifice, and secures it from an attack. The edge of the mouth is termed its *margin.*

Whorls.

Some shells are simply tubular or conical; but the greater part are variously convoluted, the volutions being termed *whorls,* or spires. These whorls are in general visible and distinct, the boundary between each being termed the *line of separation.* The whorls in some species are simply placed in a lateral position, while in others the whorls are formed upon a *pillar,* or columella, which runs in the direction of the axis of the shell, the inferior whorl in this case embracing the superior one. The pillar is in some cases nearly solid, in other instances tubular, with its base either open or covered. When the base of the tube of the columella is uncovered, the opening is termed the *pillar cavity,* or umbilicus.

Dextral shells.

In general, when a spiral shell is placed upon its base or mouth, with the apex towards the observer, the mouth will be found situated on the right side, and the whorls will be observed revolving in a direction from right to left, or corresponding with the motion of the sun. These shells are termed *dextral.* A few species have this order reversed, as the observer will readily perceive. For upon placing the shell in the above-mentioned position, the mouth will be found situated on the left side, and the whorls will revolve from left to right. These shells are termed *sinistral,* heterostrophe, or heteroclite.

Sinistral shells.

Epidermis.

Several shells are furnished externally with a thin skin, or *epidermis.* The use of this covering, we have not been able to ascertain. It is common to the other classes of shells also. Some authors have supposed that it secured the shell from being covered with vermes. If this supposition were true, we would not see the Mussles, even when very young, overrun with Zoophytes and Balani.

Explanation of Terms used in the Description of Bivalves.

Hinge.

The two sides of bivalves move upon a certain point, as a fulcrum, which is termed the *hinge.* This part in some shells is smooth, in others it is furnished with *teeth,* or small eminences, with which the inner surface of the hinge is set. On each side of the hinge there are usually small projections of the shell, which are denominated *beaks,* or umbones. These are either reflex, divaricate, or spiral. Near the hinge there is a strong cartilaginous membrane, which connects the valves, and which is termed the *ligament,* under which, and towards the beak, there is usually a groove, called a *chink.*

Base.

The *base* of bivalves is considered as situated in the beak. This has been objected to by some conchologists, and the opening or mouth, as in univalves, proposed as the proper base. But when we consider the beak as the centre of motion, containing the hinge upon which the valves turn, we feel ourselves justified in retaining the Linnæan definition, or the one already mentioned. The *margin* of the shell occupies the circumference of the valves and is divided into four parts. The *inferior margin,* or the margin of the hinge; the *anterior margin,* or the margin next to the ligament; the *posterior*

Terminology.

margin, or the margin on the side of the beaks opposite to the ligament. In this margin there is usually a small depression, or lunule. The *superior margin* occupies that portion of the shell which is situated between the ligament and posterior margin, and is opposite to the hinge. In some species, the valves are unconnected in part; these shells are said to have the *margin gaping*.

Valves. The valves of shells are divided into *right* and *left*, *equal* and *unequal*, *equilateral* and *inequilateral*. If the shell is placed upon its base or hinge, with the ligament behind, then the right and left sides of the shell will correspond with those of the observer. When both valves agree in size and form, then they are said to be equal. The *length* of a shell is in the direction of a line drawn from the beaks to the superior margin; the *breadth* is in the direction of a line drawn at right angles to the former. When the longitudinal line divides the valves into two equal parts, then the shell is said to be *equilateral*; if into unequal parts, it is termed *inequilateral*.

Cicatrix. The *cicatrix* is a mark left on the inside of the valves, at the point where the muscles adhered.

Beard. The *beard*, or byssus, is a thread-like substance by which certain species adhere to stones and rocks.

Explanation of Terms used in the Description of Multivalves.

Valves. In some of the genera, the valves are so strongly united, that they seem to form one shell; these are said to be *articulated*. In others, a membranaceous substance, termed the *ligament*, connects the valves together, and sometimes lines the cavity of the shell.

Base. The *base* is sometimes affixed to other bodies directly, or possesses an intervening tubular fleshy *peduncle*. The *accessory valves*, or operculum, in some close, the principal entrance like a lid; in others, they are united to the primary valves.

Having thus noticed, in succession, the principal conchological systems which have made their appearance; and having explained a few of the terms generally used in the science, we now proceed to lay before our readers a system of British conchology. Had we attempted to give a description of all the known species and genera which have been ascertained, we would have increased the article to an unwarrantable length; and to have confined ourselves to the description of the genera merely, would have rendered the present remarks of less general utility. We propose to give at present a description of all the British species, with a few remarks illustrative of their history; and under the article TESTACEOLOGY, to give an account of all the known genera, with an enumeration of all the species which have been referred to each genus.

Instead of adopting the Linnæan arrangement, which in many respects we view as defective and unnatural, we have only conformed to his general divisions, placing the univalves, however, in the first, and the multivalves in the last division. This was the ancient method of distributing shells, and certainly the most obvious. The student of nature is, by such a method, led from the examination of the more simple shells, to those which are more complicated in their structure, and thus pursues the plan so successfully followed in the other sciences. We have judged it expedient to make a few alterations in the distribution of the univalves, for the purpose of bringing more closely together shells naturally allied. Thus we have placed those univalves whose cavity is entire, or *unilocular*, in a separate division from those shells which are furnished with a many-celled cavity, or which may be termed *multilocular*.

The unilocular shells admit of a twofold division. Those destitute of a columella, or pillar round which the shell revolves; and those which are furnished with a columella, or pillar. This proposed arrangement, requires the formation of a few new genera. From this little confusion can arise, as we have invariably retained the *specific* appellations by which the shells are at present known, and have mentioned the genera to which they formerly belonged. We have ventured to add a few new species to the testacea of Britain, which have come under our own inspection. Of these, drawings will be given.

When describing the several species of British shells, we shall sometimes give a description of the contained animal when necessary, for the purpose of specific distinction. Under the article MOLLUSCA, we propose to lay before our readers a description of the different inhabitants of shells, with remarks illustrating their physiology.

ORDER I. UNIVALVES.

Univalves. THIS division of testaceous bodies was first proposed by Aristotle, and has been more or less employed by every succeeding conchologist. All those species are included in this division whose shell is composed of one piece, destitute of a hinge, and not furnished with any accessory valves.

The order admits of a twofold division, for the purpose of separating the unilocular shells from those which are multilocular.

DIVISION I. UNILOCULAR.

Unilocular shells. THE unilocular shells were first separated from the multilocular species by Breynius, as appears from the use which he made of the terms Monothalamia and Polythalamia. Bose has employed, for the same purpose, the terms Unilocular and Multilocular in his system. Although less expressive than the terms of Breynius, they are more generally understood. The shells of this division have a one-celled cavity, and are more simple in their formation than the multilocular testacea. They admit of a division into two sections; those which are destitute of a pillar may be termed Astulidia, and those which are furnished with a pillar Stulidia.

SECT. I. ASTULIDIA.

Astulida. The shells which we include in this section, are such as are destitute of a pillar or columella upon which they are formed. Those species which are spiral, have the whorls placed laterally, and do not revolve round the pillar. This section we propose to divide into four families, characterised by a difference in the shape of the shell. These families may be denominated expanded, tubular, flask-shaped, or spiral.

FAMILY I. EXPANDED.

In this family the cavity of the shell is open and conspicuous, and the mouth is large and spreading. It was first formed by Breynius, and named Lepas, as it included the Patellæ, which were known to Aristotle by the name of Lepas. The family contains three genera, Patella, Haliotis, and Sigaretus.

Univalves.

Genus I. Patella. *Limpet.*

I. Patella. *Shell subconical, mouth large basin-shaped.*

Obs. The inhabitants of this genus resemble the Limaces of the mollusca order of Linnæus. The species admit of distribution into six subdivisions, which Latreille has constituted into as many genera.

A. Suborbicular, simple beneath, vertex entire, margin destitute of fissures. *Patella.*

Vulgata, 1. *Vulgata.* Common Limpet. Shell subconical, with about fourteen obsolete angles, vertex nearly central, mouth subovate, margin indented; diameter about two inches.

Brit. Zool. tab. 89. fig. 145, 146.

This species is subject to numerous variations in colour and shape. The young shells are flat, with deeply indented margins and a lateral vertex. The old shells are usually smoother, more conical, and have the vertex nearly central. This is a very common shell, adhering to rocks and stones.

Cœrulea, 2. *Cœrulea.* Shell translucent, subovate, slightly wrinkled concentrically, and rayed with bluish lines from the vertex to the margin; vertex nearly central, protuberant, worn, margin waved; inside glossy, pavonine; length an inch, breadth eight-tenths, height five-tenths.

Brit. Zool. tab. 90. fig. 151.
Test. Brit. Sup. page 132.

In the young state this shell is depressed, the vertex is protuberant and lateral. In the vertex two small spots of a black colour may sometimes be observed; such shells have been hastily constituted into a distinct species under the title *P. bimaculata.* This species is common in England and Scotland. It feeds on the stalks of *Fucus digitatus,* in which it forms a circular cavity.

Pellucida, 3. *Pellucida.* Shell thin, horn coloured, rayed with dotted lines of azure, most conspicuous from the vertex to the broadest end, oval, rounded at top, with an obscure vertex at the narrow end of a black colour; margin entire even; length about an inch, breadth five-eighths, height three eighths.

Brit. Zool. tab. 90. fig. 150.
Pult. *Dorset.* tab. 33. fig. 5.
British Shells, tab. 3. fig. 1. 1. 1.

This shell varies a little in its markings. Linnæus states the number of coloured rays at four. In young specimens we have observed them entirely wanting, their place being supplied by brown lines. In the older specimens they sometimes exceed thirty, and the shell is furnished with obsolete ribs. Common on the coast of England and Scotland.

Elongata, 4. *Elongata.* Shell pale brownish white, with darker coloured obsolete rays, opake, dull, somewhat pointed before, vertex rounded; length three-tenths, breadth two-tenths, height one-tenth.

A new species found at St Andrew's, Fifeshire, by Miss Lambert.

Parva, 5. *Parva.* Shell reddish white, with about sixteen pale reddish lines from the vertex to the margin, outside dull, inside glossy, subconical, oval, slightly wrinkled concentrically; vertex a little pointed, approaching the narrow end; length about four-tenths, breadth three-tenths, height one-eighth of an inch.

Brit. Shells, tab. 21. fig. 2.
Pult. *Dorset.* tab. 14. fig. 11.

Frequent on rocks and stones about low-water mark.

Elliptica, 6. *Elliptica.* Shell elliptical, margin entire, vertex a little pointed, strong, dull, opake; length four-tenths, breadth three-tenths, height scarcely two-tenths.

This shell resembles the preceding species, and may be easily mistaken for it. The dullness, opacity, and want of coloured lines, are the marks by which it may be distinguished. A new species found on stones in Zetland.

Distorta, 7. *Distorta.* Shell subquadrangular, depressed, wrinkled. colour brown, destitute of lustre, vertex nearly central, small, margin uneven, flattened; length five-tenths, breadth four-tenths, height two-tenths.

A new species found adhering to stones dredged in deep water off the coast of Zetland.

Rota, 8. *Rota.* Shell white, opake, round, with a regularly toothed margin.

Test. Min. Rar. tab. 1. fig. 16.

A minute species from Sandwich, rare.

B. Oblong, vertex pointed and leaning on the margin. *Crepidula.*

Intorta, 9. *Intorta.* Shell ovate, with upwards of twenty equidistant tuberculated ribs, and alternate, obsolete, smaller ones; vertex towards the narrow end, and turning downwards, margin slightly indented with the ribs; length three-fourths of an inch, breadth about half an inch, the height somewhat less.

Brit. Zool. tab. 90. fig. 148.
Brit. Shells, tab. 146.

First found in Anglesea by Mr Pennant, and since on the coast of Devon and in the Frith of Forth by Mr Laskey.

Lacustris, 10. *Lacustris.* Shell entire, oval, subconical, vertex near to one end, hooked, mouth oval, margin even and thin, inside glossy, outside covered with a dark green epidermis; length three eighths, breadth two eighths, height not quite so much.

Pult. *Dorset.* tab. 22. fig. 8. 8.
Brit. Shells, tab. 147.

Common in rivulets adhering to stones, seldom to the leaves and stalks of aquatic plants.

Oblonga, 11. *Oblonga.* Shell entire, membranaceous, pale horn coloured, oblong, compressed; vertex pointed, turned to one side, mouth oval, margin entire, inside smooth, glossy, outside covered with a brownish epidermis; length four eighths, breadth two eighths, and height one eighth.

Phil. Trans. vol. lxxvi. tab. 3. fig. 1, 2, 3, 5.
Pult. *Dorset.* tab. 18. fig. 20.
Brit. Shells, tab. 150.

On plants, in ditches, and ponds; not uncommon.

C. Oval, summit produced into a beak, somewhat twisted, and reclining towards the left margin. *Concholepas.*

Antiquata, 12. *Antiquata.* Shell thick, opake, white, subconical, with concentric imbricated wrinkles, vertex obliquely pointing upwards, or extending and recurved; mouth oval, about half an inch wide.

Test. Brit. tab. 13. fig. 9.
Pult. *Dorset.* tab. 22. 72.

First observed at Weymouth by Mr Bryer, and afterwards in the Frith of Forth by Mr Laskey.

Hungarica, 13. *Hungarica.* Shell conical, striated, acuminated; vertex reflected, terminating in a spiral turn underneath; mouth circular, about an inch in diameter; margin waved; epidermis of a brown colour, with a ciliated border; height five eighths of an inch.

Brit. Zool. tab. 90. fig. 147.
Brit. Shells, tab. 21. fig. 1. 1.

Not uncommon on the west coast of England, and the east coast of Scotland.

Univalves. 14. *Militaris.* Shell subconical, decussated with fine striæ; vertex recurved, and turned to one side; mouth circular, about half an inch wide, inside glossy, white.

Test. Brit. tab. 13, fig. 11.
British Shells, tab. 171.

First noticed as British by Dr Pulteney; found at Weymouth by Mr Bryer; in Cornwall by Miss Pocock; and in the Frith of Forth by Mr Laskey.

D. Oval, subconical, with a perforated summit. *Fissurella.*

Græca, 15. *Græca.* Shell oblong, oval, thick, of a brown colour, strongly reticulated; vertex truncated, with an oblong perforation, margin somewhat indented or arcuated; length about three quarters of an inch, breadth half an inch, height a quarter.

Brit. Zool. tab. 89, fig. 153.
Pult. *Dorset.* tab. 23, fig. 3.
Brit. Shells, tab. 21, fig. 33.

Not uncommon on the English coast.

Apertura, 16. *Apertura.* Shell subconical, white, marked with strong tuberculated ribs, with a few circular ridges; vertex reflected, small, turning downwards, above which is a rhomboidal perforation; mouth oval, margin crenated; length about a quarter of an inch, height one-eighth.

Test. Brit. tab. 13, fig. 10.

Found by Mr Montagu at Falmouth and in Salcomb bay. We have observed it in Zetland.

Zetlandica, 17. *Zetlandica.* Shell white, pellucid, glossy, oblong, furrowed from the vertex to the margin with tuberculated ribs; vertex obtuse, marginal, with an oval perforation; mouth ovate, margin waved; length scarcely a line.

This new species was observed among small shells from Zetland.

Marginata, 18. *Marginata.* Shell white, pellucid, glossy, smooth, oblong; margin waved; vertex pointed, marginal, with an oval perforation, surrounded with a raised border; length about half a line.

Found with the preceding species in Zetland.

E. Posterior margin furnished with a slit, summit entire. *Emarginula.*

Fissura, 19. *Fissura.* Shell oval, conical, striated, reticulated; vertex a little reflected; mouth oval, margin crenated, with a slit behind reaching about one-fourth of the length of the shell towards the vertex, inside smooth, glossy; length half an inch, height and breadth about two-eighths.

Brit. Zool. tab. 90. Fig. 152.
Brit. Shells. tab. 3. fig. 3.

In England and Scotland not frequent.

F. Conical, cavity furnished with a thin plate, or tooth-like process. *Calyptræa.*

Chinensis. 20. *Chinensis.* Shell entire, subconical, of a pale brown or whitish colour; vertex central, slightly wrinkled concentrically; mouth circular, inside glossy, smooth, furnished with a flat thin plate, standing obliquely to the side of the shell; breadth five-eighths, height two-eighths.

Brit. Shells, tab. 129.
Test. Brit. tab. 13. fig. 44.

First noticed as British, by Col. George at Penryn. It has since been found at Salcomb bay by Mr Montagu, and in the Frith of Forth by Mr Laskey.

Genus II. Haliotis.

II. Haliotis. *Shell ear-shaped, flat, spire lateral, and nearly concealed; disk pierced with holes, in a line parallel with the inner margin; mouth wide, longer than its breadth.*

1. *Tuberculata.* Lin. Shell strong, opake, oval, striated longitudinally, and wrinkled transversely; near the inner margin, a ridge beset with tubercles, increasing in size to the front, where a few of them are pervious; inside pearlacious; length 4 inches, breadth 3 inches. Tuberculata.

Brit. Zool. tab. 88, fig. 144.
Pult. *Hist. Dorset.* tab. 22. fig. 1. 1.
Don. Brit. Shells, tab. 5.

Adheres to rocks; found after storms on the western and southern coasts of England; common in Guernsey, where the animal is used for food.

Genus III. Sigaretus.

Shell ear-shaped, with an obsolete spire, aperture large, inner margin turned inwards; disk without orifices. III. Sigaretus.

1. *Haliotoidea.* Shell thin, pellucid, white, glossy, finely wrinkled across; aperture oval, nearly extended to the apex; inner margin turned inwards, outer margin thin, membranaceous; apex small, and making nearly two volutions; length three-fourths, breadth half an inch. Haliotoidea.

Lin. *Syst. Nat.* p. 1250, No. 713. Helix haliotoidea.
Mont. *Test. Brit.* tab. 7, fig. 6. Bulla haliotoidea.
Pult. *Hutch. Dor.* tab. 22, fig. 5.*

On the coast of Devon and Dorset, by Mr Montagu; at Weymouth, by Mr Bryer; at Portobello sands, Scotland, by Mr Laskey; and we have found it in Zetland.

This shell was placed by Linnæus in the genus Helix, in the family Ovatæ imperforatæ. By Montagu, and the authors of the Descriptive Catalogue, it is placed among the Bullæ. Its form points out at once its relation to the preceding genus, with which it would have been united by Linnæus, had it possessed the row of tubercles on the disk. Its shape and inflated margin forbid its insertion either in the genus Bulla or Helix. Its animal completely envelopes the shell. The present genus was formed by Lamarck, who places it among the naked mollusca, in company with the dorris and chiton.

Family II. TUBULAR.

This family of shells was first pointed out by Langius, under the title *Tubuli marini.* Their form is that of a narrow tube, usually sub-cylindrical, or tapering to a point. The family contains three genera, *Dentalium*, *Cœcum*, and *Serpula.*

Genus IV. Dentalium.

Shell tubular, nearly straight, tapering; apex pervious. IV. Dentalium.

1. *Entalis.* Shell subarcuated, tapering to a small point, often marked with circular wrinkles and bands, colour white; length half an inch, diameter at the largest end about two-tenths. Entalis.

Brit. Zool. tab. 90, fig. 154.
Don. *B. Shells*, tab. 48.

Not uncommon in England and Scotland. It appears to be an inhabitant of deep water.

2. *Dentalis*, Lin. Shell tapering, subarcuated, very small at the point; striated longitudinally; striæ about 20 in number; length half an inch. Dentalis,

Test. Brit. p. 435. D. Striatum.

Found on the shores of Cornwall and Devon by Mr Montagu.

Univalves. Striatulum. 3. *Striatulum.* Shell tapering, subarcuated, with eight ribs or angles, and intermediate striæ.

Don. *Brit. Shells*, tab. 162. D. Octangulatum.

Found on the sandy coast of Cornwall, near Lelund, by Miss Pocock.

Gadus. 4. *Gadus.* Subarcuated, tapering, smooth, white, contracting a little toward the larger end; length about three-eighths of an inch.

Test. Brit. p. 496. tab. 14. fig. 7.

First described by Montagu, who says that it is found in many parts of the British channel, and known to mariners by the name of *Hake's-tooth.*

Genus V. Cæcum.

V. Cæcum. *Shell tubular, subcylindrical, subarcuated, undivided, and closed at the apex.*

Obs. None of the shells of this genus were known to Linnæus. Mr Boys discovered the *C. Imperforatum*, which was inserted by Mr Walker in the genus Dentalium, without sufficient consideration, as one of the characters of that genus, "*utraque extremitate pervia*," forbade its admission. The impervious apex, and cylindrical form of the Imperforatum, and two others lately discovered, point out the propriety of constituting a new genus for their reception.

Imperforatum, 1. *Imperforatum.* Shell cylindric, subarcuated, striated transversely; aperture a little contracted at the margin; apex truncated, and furnished with a small round protuberance; length one-eighth of an inch, breadth one-third of its length.

Walker's *Minute Shells*, fig. 15. Dentalium.

Found by Mr Boys at Sandwich, and by Mr Montagu at Falmouth.

Trachea, 2. *Trachea.* Subcylindric, subarcuated, with regular, strong, transverse striæ; aperture round; apex truncated, and furnished with a small round protuberance; length about one-eighth of an inch, the diameter about one-fifth of its length.

Test. Brit. p. 497. tab. 14. fig. 10. Dentalium Trachea.

Discovered by Mr Montagu in sand from Milton, Devonshire.

Glabrum. 3. *Glabrum.* Shell cylindric, arcuated, smooth, glossy; mouth orbicular; apex rounded and submarginated; length one line.

Test. Brit. p. 497. Dentalium glabrum.

Discovered by Mr Montagu in Biddeford Bay, and at Barnstable, Devonshire; Capt. Laskey has observed it at Dunbar; and we have found it in Zetland

Genus VI. Serpula.

VI. Serpula. *Shell tubular, flexuous, contorted, adhering to other bodies.*

Obs. The inhabitants of this genus of shells belong to the class Annelides of Latreille, and may with propriety be divided into several genera. Their history is still involved in much obscurity.

Vermicularis, 1. *Vermicularis.* Shell round, opake, flexuous, tapering to a fine point, wrinkled transversely, and attached throughout its whole length to other bodies. Diameter sometimes as large as a swan's quill; length from three to four inches.

Brit. Zool tab. 91. fig. 158.

Pult. *Hush. Dorset.* tab. 22. fig. 9.

This is a common shell, adhering to stones, old shells, and corals. It is subject to considerable variation in its shape. The Serpula Intricata of Linnæus may be referred to this species.

The annimal resembles a *Terebella.* It is furnished with branched ciliated tentacula, which are spotted with crimson, and when extended, almost surround a double funnel-shaped proboscis.

Triquetra, 2. *Triquetra.* Shell strong, white, opake, contorted, wrinkled transversely, base spreading, back furnished with a keel or ridge. Diameter one-tenth of an inch.

Brit. Zool. tab. 91. fig. 157. S. Contortuplicata.

Brit. Shells, tab. 95. S. Vermicularis, exclusive of the middle and right hand figures.

This shell is very common, adhering to shells and stones, or twisted round the stalks of fuci. It varies much in shape, being sometimes nearly destitute of any dorsal ridge, and occasionally furnished with two small lateral ridges.

The inhabitant, as described by Mr Montagu, and figured by Ellis, (*Corallines*, tab. 38. fig. 2.), possesses two tentacula, which are plumose, or furnished with numerous ciliated fibres, varying in colour, being barred with blue, yellow, brown, or red. The trumpet-shaped proboscis is finely striated, and the margin crenated.

Mr Montagu likewise found four other animals inhabiting shells of similar form, as the triquetra, yet different from the one which is now described. 1. With a smooth and slightly concave *testaceous* termination or operculum. 2. With a testaceous termination, armed with two or three spines in front. 3. With a testaceous conical termination. 4. With a smooth termination, grooved on each side for the reception of two *cirri* placed at the base of the operculum, which is corneous, and furnished with a bifid stile.

Serrulata, 3. *Serrulata.* Shell transparent, smooth, glossy, triangular, tapering, flexuous, base spreading, adhering; dorsal ridge serrated, and a little produced at the opening. Breadth at the base two-tenths of an inch, length about three inches.

This new species was found in Zetland in 1809, adhering to stones brought from deep water, to which it is attached throughout. Its transparency and lustre, independent of other characters, entitle it to a separate place in the system.

Tubularia, 4. *Tubularia.* Shell white, opake, round, tapering, slightly wrinkled transversely, adhering at the smaller end, and irregularly flexuous. Diameter two-tenths of an inch, length seven inches.

Test. Brit. p. 513.

It was first observed at Torcross, Devonshire, by Mr Montagu. It is found in Zetland, along with the preceding species.

Mr Montagu observes, that the animal is an amphitrite, with between fifty and sixty annulations. The head is long, white, and barred with green, having a loose scalloped dilatable membrane on each side. Tentacula two, beautifully feathered, each originating from a single stalk, and placed near to each other, on the forepart of the head.

Family III. FLASK-SHAPED.

The shells included in this family were unknown to Linnæus. They are furnished with a one-celled cavity, are destitute of a spire, and in shape resemble a bottle or flask. The family contains only one genus, which is denominated Lagena.

Univalves.

Genus VII. Lagena.

VII. Lagena. *Shell Bottle-shaped, not attached to other bodies.*

Obs. We are indebted to Mr Walker for the information which we possess concerning the species of this genus. They were termed by him Lagena, but unaccountably referred to the Linnæan genus of Serpula. In *Testacea Britannica,* they are included in the genus Vermiculum. All those species which are at present known, require the aid of the microscope for their examination.

Striata, 1. *Striata.* Shell pellucid, glossy, white, with opake longitudinal striæ, suboval; mouth produced, tubular, small; length about half a line.

Walker's *Test. Min. Rar.* tab. 1. fig. 6.

Among sand on the English shores, not uncommon.

Globosa, 2. *Globosa.* Shell white, transparent, smooth, subovate; mouth small and round.

Walker's *Test. Min. Rar.* tab. 1. fig. 8.

Found at Sandwich, rare.

Lævis, 3. *Lævis.* Shell bluish white, transparent, smooth, oblong; mouth produced cylindrical.

Walker's *Test. Min. Rar.* tab. 1. fig. 9.

From Sandwich, rare.

Marginata, 4. *Marginata.* Shell white, transparent, glossy, subovate, subcompressed, margin elevated; mouth a little produced.

Walker's *Test. Min. Rar.* tab. 1. fig. 7.

Found at Reculver, Kent, by Mr Walker, and on the coast of Devon by Mr Montagu.

Retorta, 5. *Retorta.* Shell white, opake, suborbicular, margin elevated; mouth produced recurved; diameter not half a line.

Walker's *Test. Min. Rar.* tab. 1. fig. 10.

From Sandwich, rare.

Perlucida, 6. *Perlucida.* Shell white, transparent, glossy, globubular, with six equidistant longitudinal ribs, and a small knob at the base; neck produced, mouth small; length one-tenth of an inch.

Test. Brit. tab. 14. fig. 3.

Found at Sea Salter, Kent, by Mr Boys.

Urnæ, 7. *Urnæ.* Shell white, semitransparent, glossy, smooth, urn-shaped, base furnished with a knob, mouth produced, neck conical; length one line.

Test. Brit. tab. 14. fig. 1.

Found by Mr Boys among sand from Sheppey island.

Squamosa. 8. *Squamosa.* Shell globose, mouth a little produced, striated, the striæ appearing like the scales of a fish.

Test. Brit. tab. 14. fig. 2.

A minute species, found at Sea Salter by Mr Boys.

Family IV. SPIRAL.

In this division of shells, are included such spiral univalves as are destitute of a pillar, and whose whorls or volutions are placed laterally, so that the last whorl is on the outside forming the Margin. The family possesses two genera, Spirorbis and Planorbis.

Genus VIII. Spirorbis.

VIII. Spirorbis. *Shell spiral, aperture orbicular, base adhering to other bodies.*

Obs. The species of this genus live in the sea, and adhere to rocks, old shells, sea-weed, and corals. They were included by Linnæus in his genus Serpula. The inhabitants belong to the class *Annelides* of Latreille. The genus admits of two subdivisions.

A. Mouth Dextral.

Communis, 1. *Communis.* Shell opake, with three or four regular lateral whirls, round on the upper part, and a little wrinkled, with a cavity in the centre, base spreading, diameter one eighth of an inch.

Serpula spirorbis. *Brit. Zool.* tab. 91. fig. 155.

Donov. *Brit. Sh.* tab. 9.

Animal furnished with branched ciliated tentacula, and a clavate or subfunnel shaped proboscis. Common on stones, shells, and algæ.

Spirilium, 2. *Spirilium.* Shell white, glossy, subpellucid, with two or three subcylindrical whorls a little wrinkled, sometimes placed laterally, and often rising one above the other; diameter one line.

Pultney, *Hist. Dor.* tab. 19. fig. 27.

This species usually resides on Algæ; and, although it resembles in appearance the former species, is never found in its company.

Granulatus, 3. *Granulatus.* Shell white, opake, with two volutions deeply grooved longitudinally, and wrinkled transversely, size of the *Spirorbis.*

Donovan, *Brit. Sh.* tab. 100.

Animal of a buff colour, with ten ciliated rays. Found on stones and old shells.

Carinatus, 4. *Carinatus.* Shell white, opake, dull, outer whorl rising into a carinated ridge on the top, middle concave, interior volution inconspicuous, base a little spreading.

Test. Brit. p. 502.

Adheres to old shells. Common to England and Scotland.

Corrugatus, 5. *Corrugatus.* Shell white, glossy, strong, transversely wrinkled, a small portion only of the second volution visible, centre with a cavity; diameter about one-eighth of an inch.

Test. Brit. p. 502.

Animal orange red, with eight greenish ciliated rays, and a subfunnel shaped proboscis of the same colour. Found on slate rocks at Milton, by Mr Montagu.

Corneus, 6. *Corneus.* Shell horn coloured, regular, round, with three whirls.

Lin. trans. v. tab. 1. fig. 33, 34, 35.

Found at Pembroke, by Mr Adams.

B. Mouth Sinistral.

Heterostrophus, 7. *Heterostrophus.* Shell white, dull, strong, with two or three whorls placed laterally, furnished with three longitudinal ridges, wrinkled transversely, base flat; spreading; diameter a line.

Test. Brit. p. 503.

Found on stones, shells, any algæ, common.

Sinistrorsus, 8. *Sinistrorsus.* Shell white, glossy, semipellucid, with two or three lateral whorls frequently coiled upon one another, and slightly wrinkled transversely; diameter a line.

Walker's *Test. Min. Rar.* tab. 1. fig. 13, 14.

Usually found on lobsters; we have observed it on old shells of *Cardium aculeatum.*

Minutus, 9. *Minutus.* Shell dirty white, with two or three lateral whorls, wrinkled transversely, and sometimes furnished with a dorsal carina, base rounded; diameter a quarter of a line.

Test. Brit. p. 505.

Animal with ciliated feelers and a clavate proboscis. Inhabits the branches of *Corallina officinalis.*

Conicus, 10. *Conicus.* Shell dirty white, dull, opake, whirls two, the outer one large, and embracing the other, with a carina along the upper side, conical, mouth towards the top.

In a young state, it resembles the preceding species;

Univalves. when old it becomes conical. Found on old shells in Zetland.

Lucidus, 11. *Lucidus.* Shell white, glossy, pellucid, irregular, whorls two or three, sometimes lateral, and often projecting upwards and unconnected, diameter half a line.

Test. Brit. p. 506.

Animal red, with plumose tentacula of a pale colour, and two brown spots on the head. Frequent on corallines, especially *Sertularia abietina.*

Reversus. 12. *Reversus.* Shell white, rugose, subcylindric, subspiral, tapering to a small point; diameter at the larger end one-tenth of an inch.

Test. Brit. p. 508.

Found on *Pecten opercularis,* on the coast of Devon, by Mr Montague.

Genus IX. Planorbis.

IX. Planorbis. *Shell simple spiral depressed, spires lateral, mouth oblique.*

Obs. The species of this genus were included among the Helices by Linnæus. The continental naturalists have long ago separated them, and constituted the present genus. They possess many characters in common. They are all of a horn colour, subpellucid, and the mouth is placed obliquely to the direction of the whirls. They inhabit fresh water ditches, ponds, and rivers. The base of these shells is known by its being more sunk in than the upper side, and, from the gradual diminution of the whorls towards the centre, forming a funnel-shaped cavity.

Corneus, 1. *Corneus.* Shell brownish coloured, subpellucid, whorls four, rounded, separated by a deep spiral line, apex much depressed, forming a cavity, underside a little concave, wrinkled transversely; mouth sublunated; diameter an inch and quarter.

Brit. Zool. tab. 83. fig. 26. H. corneus.
Brit. Shells, tab. 39. fig. 1.

Common in England, in ditches, and old drains.

Complanatus. 2. *Complanatus.* Shell with five whorls gradually dcereasing to the centre, rounded, separated by a deep spiral line, wrinkled transversely, margin carinated, terminating at the inferior angle of the mouth, diameter five-eighths of an inch.

Test. Brit. tab. 25. fig. 4. Helix complanatus.
Brit. Zool. tab. 82. fig. 123. H. planorbis.

Animal dusky, with two long slender setaceous tentacula of the same colour, opake, dark in the middle. Common in ditches, in England and near Edinburgh.

Carinatus. 3. *Carinatus.* Shell a little glossy, whorls four, wrinkled across, outer one broad, sloping to a carina on both sides, which enters the mouth, the inner whirls decrease suddenly to the centre, where is a small cavity, base nearly flat, diameter about three-fourths of an inch.

Lin. *Syst.* Helix planorbis.
Test. Brit. tab. 25. fig. 1.
Lin. Trans. vol. viii. tab. 5. fig. 14.

The animal differs from the preceding species in the tentacula, being somewhat longer, pellucid, yellow, and not darker in the middle. In ditches and ponds, in England frequent, and near Edinburgh.

Vortex, 4. *Vortex.* Shell with six or seven whirls, above concave, beneath flat, even, marked with a fine separating line, exterior whorl subcarinated at the lower edge, diameter scarcely half an inch.

Test. Brit. tab. 25. fig. 3.
Brit. Zool. tab. 83. fig. 124.
Brit. Shells, tab. 75.

Anima dusky, with two long filiform tentacula, and two black eyes placed at their base. Common in England, in ponds and ditches. Univalves.

Spirorbis, 5. *Spirorbis.* Shell with six whorls exactly lateral, round, both sides flat; diameter three-tenths of an inch.

Test. Brit. tab. 25. fig. 2.

In rivers and ditches, England, and at Livingstone, West-Lothian.

Contortus, 6. *Contortus.* Shell with five or six whorls, the outer one rounded; above even, the whirls divided by a separating line, with a cavity in the centre; beneath with a large central cavity; mouth bent, embracing the body whorl; diameter about one-tenth of an inch.

Test. Brit. tab. 25. fig. 6.
Brit. Shells, tab. 99.

Animal dusky, with two long filiform tentacula, with the eyes placed at their base. In ditches in England, rather a local species, and near Edinburgh and Cupar.

Albus, 7. *Albus.* Shell with four lateral compressed whorls, the outer one subcarinated; above the apex a little depressed; beneath it is furnished with a cavity; striated transversely and longitudinally; mouth clasping the body whorl; diameter a quarter of an inch.

Test. Brit. tab. 25. fig. 7.
Pult. Dorset. tab. 19. fig. 18.

Animal light coloured, with two long filiform tentacula, with two eyes at their base on the top of the head. Frequent in rivers and ponds in England; found also at Dunbar, by Mr Laskey.

Cristatus, 8. *Cristatus.* Shell with three or four rounded whirls striated transversely; above, the apex is little sunk, beneath there is a cavity; aperture orbicular; diameter one-tenth of an inch.

Test. Min. Rar. tab. 1. fig. 18.
Test. Brit. vignette 1. fig. 7, 8.

Animal dusky, with four tentacula, and a plumose appendage, the body lobated in front. In England rare.

Fontanus, 9. *Fontanus.* Shell smooth, glossy, nearly equal on both sides, above, subdepressed, the cavity beneath, large and exhibiting the volutions; whorls four, the outer one subcarinated; diameter two-tenths.

Test. Brit. tab. 6. fig. 6.

Animal light chesnut, with two filiform tentacula, head long. Frequent in England, has been found at Cupar.

Nautileus. 10. *Nautileus.* Shell with four whorls, ribbed across, with a subspinous carina, above flat, beneath with a large cavity; diameter one-eighth of an inch.

Test. Min. Rar. tab. 1. fig. 20, 21.
Test. Brit. tab. 25. fig. 5.

Animal of a pale colour, tentacula, two setaceous; eyes on the head at the base of the tentacula. In ponds and ditches, in England frequent.

SECT. II. STULIDIA.

Stulidia. The shells included in this Section are all of them more or less spiral and revolve round a central pillar, or columella, as it is sometimes called. The genera of this Section admit of distribution into three families, Turreted, Globose, and Convoluted.

Family I. TURRETED.

The shells of this family have their whorls much produced above, and are of a lengthened conical form. The length of the shell usually exceeding greatly the breadth of it. This family includes six genera, Buccinum, Murex, Strombus, Turbo, Odostomia, and Lymnæa. These genera admit of distribution into two tribes,

Univalves.

the Canaliculated and the Entire; the three first belong to the former, and the remaining genera to the latter.

Tribe 1. *Canaliculated.*

In shells of this tribe, the mouth at the base terminates in a grooved beak, more or less produced. The tribe contains three genera, Buccinum, Murex, and Strombus, which, in many respects, are nearly allied to one another.

GENUS X. BUCCINUM.

X. Buccinum. *Shell spiral, gibbous; produced, aperture ovate, ending in a short canal leaning to the right; pillar lip expanding.*

Undatum, 1. *Undatum.* Shell with seven or eight ventricose spires, with waved ribs, striated transversely and longitudinally, strong, sometimes five inches in length.

Brit. Zool. tab. 73, 74.

In its young state, this shell has an obtuse globular apex, and has been described as a distinct species by some authors. Common on all our shores.

Glaciale, 2. *Glaciale.* Shell tapering, livid brown, with about nine spirally striated volutions, the top of each spire furnished with waved ribs; body whorl usually furnished with a small ridge or keel; aperture ovate, outer lip thin, spreading; length about two inches.

Brit. Shells, tab. 154.

Found by Mr Agnew among the Orkney Isles.

Lapillus, 3. *Lapillus.* Shell thick, with five or six strongly striated spires; outer lip waved, or subdenticulated; pillar lip smooth, replicated; length seldom above two inches.

Brit. Zool. tab. 72. fig. 89.
Brit. Shells, tab. 11.

This species varies in appearance in different stages of its growth. It is placed by Lamark in his genus *Purpura.* It is common on the rocks on every part of the coast. The animal yields an unchangeable crimson dye.

Reticulatum, 4. *Reticulatum.* Shell with seven or eight ribbed spires, tapering to a fine point, wrinkled across, decussated; aperture suboval; outer lip even, denticulated within; length about an inch and a half.

Brit. Zool. tab. 72. fig. 92.
Brit. Shells, tab. 76.

Not uncommon in England and Scotland.

Macula, 5. *Macula.* Shell with six or seven ribbed spires, transversely striated; apex pointed; mouth suborbicular; outer lip globose at the back; denticulated within; inner lip replicated, and faintly denticulated; outer edge of the canal purplish; length about half an inch, breadth a quarter.

Test. Brit. tab. 8. fig. 4.

Common on the coasts of England and Scotland.

Ambiguum, 6. *Ambiguum.* Shell subconical, faintly striated transversely, with six to fifteen ribs; mouth suborbicular; outer lip thickened, slightly denticulate; inner lip folded back; length about half an inch.

Test. Brit. tab. 9. fig. 7.

Not frequent; found at Weymouth and Portland.

Hepaticum, 7. *Hepaticum.* Shell brownish, with seven or eight ribbed volutions, a transverse depression near the top of each of the spires, which are tumid, and strongly divided; apex sharp; outer lip thick, turning inwards to an edge; inner lip folded back; about an inch in length.

Test. Brit. tab. 8. fig. 1.

Found at Purbeck and at Weymouth, by Dr Pulteney.

Bilineatum. 8. *Bilineatum.* Shell ovate, smooth, girded with two to four bands of brown spots, the upper part set round with two series of tubercles; mouth large, suboval; outer lip slightly dentated, inner lip rugose and granulated.

Brit. Zool. App. tab. 79. bottom figures.

Found at Weymouth by Mr Pennant.

Perdix, 9. *Perdix.* Shell suboval, with five or six volutions, the first large and tumid, the others small in proportion, marked with small transverse ridges; mouth large oval, outer lip thin plain.

Test. Brit. tab. 8. fig. 5.

Found at Weymouth by Dr Pulteney and Mr Bryer, and on Iona by Mr Laskey.

Lineatum, 10. *Lineatum.* Shell smooth conical, with five or six spires, regularly banded with alternate spiral lines of brown and white; apex pointed; mouth oval; length a quarter of an inch, breadth one-eighth.

Brit. Shells, tab. 15.

On the English shores; rare.

Cinctum, 11. *Cinctum.* Shell white conical, marked with a fine thread-like girdle of a rufous brown colour round the middle of each spire, volutions six or seven, nearly even, finely and closely ribbed, obsoletely striated across; apex sharp; mouth narrow, outer lip thick, toothed within; length scarcely a quarter of an inch.

Test. Brit. tab. 15. fig. 1.

Found by Mr Bryer on the shore near Weymouth.

Minimum, 12. *Minimum.* Shell with fine reticulated taper spires, mouth oval, both lips smooth; length about two-tenths of an inch.

Test. Brit. tab. 8. fig. 2.

Found on the coast of Devon by Mr Montagu, and at Dunbar by Mr Laskey.

Terrestre, 13. *Terrestre.* Shell with six slender smooth white spires, terminating in an obtuse point; mouth oblong suboval, outer lip thin, even, pillar lip thickened; length nearly a quarter of an inch.

Test. Brit. tab. 8. fig. 3.

Found in England, rare; at Dunbar by Mr Laskey.

Obtusulum, 14. *Obtusulum.* Shell with three bellied spires, and an oval aperture, opake, white.

Test. Min. Rar. tab. 2. fig. 59.

A microscopic species found at Feversham creek by Mr Walker.

Breve, 15. *Breve.* Shell white, opake, short, with fine whorls, longitudinally ribbed, and transversely striated.

Lin. Trans. vol. iii. tab. 13. fig. 3. 4.

Minutum, 16. *Minutum.* Shell white, opake, with three longitudinally ribbed whorls.

Lin. Trans. vol. iii. tab. 13. fig. 5. 6.

Læve, 17. *Læve.* Shell white, opake, mouth oval, spires three, smooth, the first ventricose.

Lin. Trans. vol. iii. tab. 13. fig. 7. 8.

Obtusissimum. 18. *Obtusissimum.* Shell white, with three smooth spires, mouth contracted.

Lin. Trans. vol. iii. tab. 13. fig. 9. 10.

The four preceding species were found on the coast of Pembrokeshire by Mr Adams.

GENUS XI. MUREX.

XI. Murex. *Shell spiral, rough, with membranaceous folds; mouth*

Univalves. *oval, ending in an entire straight or slightly ascending canal.*

Obs. This genus is nearly allied to the former, and is principally distinguished from it by the greater length of the canal. We have, for the present, formed this genus into three families.

A. Canal short, spires furnished with foliated tubercles.

Erinaceus, 1. *Erinaceus.* Shell strong angulated, with six or seven spires, terminating in a fine point; each volution is furnished with six or seven rugged prominent longitudinal ribs; canal tubular; length an inch and three quarters, and nearly an inch wide.

Brit. Zool. tab. 76. fig. 95.

Brit. Shells, tab. 35.

Frequent on the English and Scottish shores.

B. Canal short, shell tapering.

Subulatus, 2. *Subulatus.* Shell slender, white, with about fifteen spires a little elevated, defined by a purplish brown line, each wrought with two rows of beads divided by a depressed line; mouth small, canal short, and turning to the left; base smooth; length three-eighths of an inch.

Test. Brit tab. 30. fig. 6.

Found amongst sea-sand in the sound of Mull

Fuscatus, 3. *Fuscatus.* Shell with ten or twelve tuberculated spires, tapering to a fine point; volutions wrought with three or four series of crenulated striæ between the tuberculated spiral ridges; mouth small, oval, ending in a slight canal.

Brit. Zool. tab. 83. fig. 3.

Found by Mr Pennant on the coast of Northumberland, by Mr Bryer at Weymouth, and by Mr Laskey at Jura.

Reticulatus, 4. *Reticulatus.* Shell with eleven or twelve reticulated volutions, strong, slender, tapering, four spiral ridges on each volution, crossed with longitudinal furrows; mouth oval, angulated at the upper part; length five-eighths of an inch.

Pult. *Dorset.* tab. 14. fig. 13.

Not uncommon on the English coast, also on the west coast of Scotland.

Tubercularis, 5. *Tubercularis.* Shell with nine or ten slender, taper, tuberculated spires, separated only by a slight depression, with three series of tubercles of equal size on each volution; length a quarter of an inch.

Test. Brit. p. 270.

Found in Devonshire by Mr Montagu, at Sandwich by Mr Boys, and at Dunbar by Mr Laskey.

Adversus, 6. *Adversus.* Spires sinistral, tuberculated, tapering to a fine point; volutions scarcely defined by the separating line, with three series of tubercles on each; mouth oval; ending in a straight canal; length three-eighths of an inch.

Test. Min. Rar. tab. 2. fig. 48.

Brit. Shells, tab. 15.

Found by Mr Walker at Sandwich, Miss Pocock in Cornwall, Mr Montagu in Devon, and by Mr Laskey at Dunbar.

C. Canal produced.

Gracilis, 7. *Gracilis.* Shell with thirteen ribs, purplish brown at the junction of the spires, with a white band round the middle of the body whorl; volutions with twelve ribs, separated at the juncture of each spire by a flat space, striated across.

Test. Brit. tab. 15. fig. 5.

Found at Biddeford Bay by Mr Montagu, at Portland by Mr Bryer, and at Dunbar by Mr Laskey.

8. *Accinctus.* Shell with six or seven costated volutions; the ribs are slightly angulated; whorls with spiral striæ; canal short; lip entire at the upper angle; length four lines. Accinctus,

Mem. Wernerian Soc. vol. i. tab. 8. fig. 14.

In the Frith of Forth by Mr Laskey.

9. *Attenuatus.* Shell with eight spires, destitute of striæ, and furnished with nine strong equidistant ribs; volutions scarcely raised; mouth narrow; outer lip thickened at the back with a rib, inner lip plain; length half an inch. Attenuatus,

Test. Brit. tab. 9. fig. 6.

Found at Falmouth harbour and Biddeford bay by Mr Montagu.

10. *Nebula.* Shell with eight taper costated spires, terminating in a sharp point, finely reticulated; volutions scarcely separated; mouth narrow, oblong; outer lip sharp, inner lip replicate; upwards of half an inch in length. Nebula.

Test. Brit. tab. 15. fig. 6.

Found by Mr Montagu on the English coast.

11. *Costatus.* Shell with six taper volutions; with eight or nine elevated ribs, without striæ; mouth narrow; outer lip usually thickened by a rib at the back, margin thin; length three-tenths of an inch. Costatus,

Brit. Shells, tab. 91.

On the English coast not common, Mr Laskey has found it at Dunbar, and we have it from Zetland.

12. *Proximus.* Shell thick, white, with six strongly costated spires; apex moderately pointed; mouth ovate, oblong; outer lip broad, reflexed; canal short, and rather spreading at the end; length about half an inch. Proximus,

Test. Brit. tab. 30. fig. 8.

Found by Mr Laskey at Dunbar.

13. *Septangularis.* Shell with eight strong, smooth, taper whorls, with seven longitudinal ridges, that run the whole length of the shell; mouth oblong, oval; outer lip sharp at the edge; length five-eighths of an inch. Septangularis,

Brit. Shells, tab. 179. fig. 4.

Test Brit. tab. 9. fig. 5.

Found at Falmouth and Salcomb bay by Mr Montagu, and at Weymouth by Mr Bryer.

14. *Turricula.* Shell with seven taper ribbed spires terminating in a fine point, and striated transversely; volutions rise perpendicularly above one another, the top of each being almost flat, and the ribs at that part are angulated; mouth narrow; length three quarters of an inch. Turricula.

Test. Brit. tab. 9. fig. 1.

In England and Scotland not uncommon.

15. *Rufus.* Shell with six taper-ribbed spires of a pale rufous brown colour; whorls furnished with about sixteen small ribs striated across; mouth narrow; canal short; pillar lip smooth; outer lip smooth, rarely thickened by a rib; length three-tenths of an inch. Rufus,

Test. Brit. p. 263.

On the English shores by Mr Montagu, at Dunbar by Mr Laskey.

16. *Gyrinus.* Shell strong, short, conic, with four brown whorls regularly covered with dark chesnut coloured tubercles, eight in a row on the body whorl, and three on the succeeding volution; length about a quarter of an inch. Gyrinus,

2

Univalves.

Mem. Wer. Soc. vol. i. tab. 8. fig. 10.

Sinuosus, 17. *Sinuosus.* Shell with six spires and six or seven ribs on each, striated across; volutions little raised; at the upper angle of the mouth a deep sinus; outer lip slightly thickened by a rib; length three quarters of an inch.

Test. Brit. tab. 9. fig. 8.

Found at Weymouth by Mr Bryer, and at Dunbar by Mr Laskey.

Antiquus, 18. *Antiquus.* Shell thick, strong, with eight whorls, ventricose; faintly striated longitudinally and transversely; mouth sub-oval; outer lip plain; inner lip replicated; inside yellowish; length about six inches.

Brit. Zool. tab. 78.

Brit. Shells, tab. 31.

Common on the British shores. It is used in Zetland as a lamp, the canal serves to hold the wick, the cavity contains the oil and the shell is suspended horizontally by a cord.

Subantiquatus, 19. *Subantiquatus.* Shell with eight whorls, striated transversely, and obsoletely ribbed longitudinally, the middle of each volution rising into a strong undulated carniated ridge, sometimes two; mouth oval; canal long; outer lip even; length three inches and a half.

Brit. Shells, tab. 119.

Said to have been found on the Scottish coast.

Carinatus, 20. *Carinatus.* Shell oblong of six spires, with two smooth spiral ridges; first whorl ventricose, aperture semicircular; length nearly four inches.

Brit. Zool. tab. 77.

Brit. Shells, tab. 109.

First figured and described by Mr Pennant, from the Portland cabinet; it has since been found by Mr Laskey at Dunbar.

Corneus, 21. *Corneus.* Shell with eight strong taper spires, transversely striated, and wrinkled longitudinally; whorls round, divided by a strong separating line; mouth oval; canal long, a little reflected; length three inches.

Brit. Zool. tab. 76. fig. 99.

Brit. Shells, tab. 38.

Common on the British shores.

Linearis, 22. *Linearis.* Shell rugose, with eight rounded and strongly ribbed whorls, crossed by elevated striæ, the summits of which are purplish brown; mouth oval; outer lip thickened at the back with a rib, crenated within; pillar lip smooth; length a quarter of an inch.

Test. Brit. tab. 9. fig. 4.

Brit. Shells, tab. 179. fig. 3.

Frequent on the English coast, found also at Dunbar by Mr Laskey.

Purpureus, 23. *Purpureus.* Shell rugose, of a dark purple colour, with spots of white, whorls ten, rounded, tapering, furnished with twenty oblique ribs, crossed by sharp ridges, mouth narrow, columella striated; length five-eighths of an inch.

Test. Brit. tab. 9. fig. 2.

On the coast of Devon by Mr Montague, and in Leith Roads by Mr Laskey.

Muricatus, 24. *Muricatus.* Shell strong, rough, with six or seven ventricose tuberculated volutions, tapering to a fine point; mouth oval, terminating in a long slender canal, outer lip dentated at the edge; length half an inch.

Test. Brit. tab. 9. fig. 2.

Found in Salcomb Bay by Mr Montagu, and at Dunbar by Mr Laskey.

Bamfius, 25. *Bamfius.* Shell ventricose, white, ribbed longitudinally, with acute plaits; mouth ovate; canal turning a little to the left; length about three-quarters of an inch. Univalves.

Brit. Shells, tab. 169, fig. 2.

Frequent on the Scottish coast, where it was first observed by the Rev. Mr Cordiner at Banff.

26. *Minutissimus.* Shell with fine spirally striated whorls, and remote ribs; canal closed. Minutissimus.

Lin. Trans. vol. iii. p. 65.

A minute species, found at Pembroke by Mr Adams.

Genus XII. Strombus.

Shell spiral, aperture much dilated, lip expanding, and produced into a groove, leaning to the left. XII. Strombus.

Obs. Young shells of this genus nearly resemble the species of the genus Murex, being destitute of the expansion of the outer lip.

1. *Pes Pelecani.* Shell pyramidal, with ten tuberculated whorls; outer lip expanded and quadrifid; canal produced; length about two inches. Pes Pelecani,

Brit. Zool. tab. 75.

Brit. Shells, tab. 4.

Common on the British shores.

2. *Costatus.* Shell with eleven dark brown volutions, tapering to a fine point, with close set ribs, and an elevated spiral line; mouth suborbicular, outer lip a little expanded, inner lip smooth, with a subcanal; length scarcely half an inch. Costatus.

Brit. Shells, tab. 94.

Test. Brit. tab. 30, fig. 7.

In England rare; at the Sound of Iona Mr Laskey; and we have found it at St Andrews.

Tribe 2. Entire.

In this tribe, the base of the aperture is entire, and not produced and grooved, as in the former. It contains three genera, *Turbo, Odostomia,* and *Lymnæa.*

Genus XIII. Turbo.

Shell spiral, produced, mouth contracted, orbicular, entire. XIII. Turbo.

A. Imperforate, first whorl ventricose; pillar-margin of the mouth dilated.

1. *Littoreus.* Shell strong with five whorls, first large, others nearly flat; outer lip thin, inner lip thick and strong; length about an inch. Littoreus,

Brit. Shells, tab. 33. fig. 1.

Animal striped with black; tentacula two, setaceous, annulated, with eyes at the base. Common on marine rocks.

2. *Tenebrosus.* Shell conical, with five ventricose spires; apex obtusely pointed; outer lip thin, spreading a little at the lower angle; diameter about a quarter of an inch. Tenebrosus,

Test. Brit. page 303.

Found on the English coast by Mr Montagu.

3. *Rudis.* Shell strong, with five ventricose whorls, well defined by the separating line, and sometimes spirally striated; inner lip thick, a little reflected; colour, yellow or brown; length three quarters of an inch. Rudis.

Brit. Shells, tab. 33. fig. 3.

Animal yellowish, with two setaceous tentacula of the same colour, most commonly marked with a longitudinal dusky streak on the outside. Not uncommon.

4. *Striatulus.* Shell with five volutions, each terminated in a flat top; base wrought with spiral striæ, which, towards the upper part, rise into three elevated Striatulus,

Univalves. membranaceous ridges; mouth angulated at the upper part; length two-tenths of an inch.

Test. Brit. tab. 10, fig. 5.

Found in Cornwall, Falmouth, and the coast of South Devon.

Jugosus, 5. *Jugosus.* Shell with four spirally ridged whorls, the first very large, occupying three-fourths of the shell; outer lip thin, sub-crenated at the edges; pillar lip broad and smooth; diameter scarcely half an inch.

Test. Brit. tab. 20, fig. 2.

Lin. Trans. vol. viii. tab. 4, fig. 7.

Found by Mr Knight in Dorset, by Mr Gibbs in Cornwall, and by Mr Laskey at Dunbar.

Mammillatus, 6. *Mammillatus.* Shell imperforate, subovate, whorls striated with raised dots and slightly angulated by a few of these striæ, the dots of which are larger.

Brit. Shells, tab. 173.

Found by Mr Plat on the Scilly rocks, at the western extremity of Cornwall, and communicated by him to Da Costa.

B. Imperforate, long, tapering.

Terebra, 7. *Terebra.* Shell with about sixteen volutions, terminating in a very fine point; larger whorls, somewhat rounded, and marked with spiral striæ; outer lip thin, fragile and semipellucid; length about two inches; breadth at the base, five-eighths.

Brit. Zool. tab. 81, fig. 113.

Animal yellowish, striped with dusky; tentacula two, short, with the eyes placed at the base. Common.

Cinctus, 8. *Cinctus.* Shell with fourteen raised volutions, separated by a deep depression, wrought with obsolete spiral striæ, with two strong elevated ridges in the middle of each volution, covered with undulated coloured lines; length two inches and a half; breadth, at the base, five-eighths of an inch.

Brit. Shells, tab. 22, fig. 1.

On the English coast, not common.

Nitidissimus, 9. *Nitidissimus.* Shell with nine extremely slender, smooth, pellucid, white spires, terminating in a fine point; the volutions are greatly raised and much rounded, and separated by a deep depression; aperture sub-orbicular; inner lip a little reflected; length one-eighth of an inch.

Test. Brit. tab. 12, fig. 1.

Found at Falmouth harbour by Mr Montagu.

Subtruncatus, 10. *Subtruncatus.* Shell with seven rounded smooth whorls, separated by a deep depressed line; colour pellucid yellowish white; length two tenths of an inch.

Test. Brit. tab. 10, fig. 1.

Found by Mr Montagu at Southampton and Falmouth; by Mr Laskey at Dunbar.

Truncatus, 11. *Truncatus.* Shell cylindric, smooth, glossy, horn-coloured, with four spires, apex abrupt; volutions considerably raised, aperture slightly emarginated; length two-tenths of an inch.

Test. Brit. tab. 10, fig. 7.

On the English coast frequent; has also been taken at Dunbar by Mr Laskey.

C. Furnished with ridges crossing the whorls.

Clathrus, 12. *Clathrus.* Shell with twelve taper spires, volutions rounded, barred the whole length of the shell with from nine to twelve regular distant membranaceous ribs; margin of the mouth thickened by a rib that surrounds it; length an inch and a half; breadth at the base half an inch.

Brit. Zool. tab. 81. fig. 111.

Animal with a long tubular proboscis, slender tentacula, and a white sustentaculum. On the British shores, not uncommon.

Clathratulus, 13. *Clathratulus.* Shell with six volutions, ribbed across with fifteen ridges; nearly resembles the preceding, but is more slender; length about half an inch.

Test. Min. Rar. tab. 2. fig. 45.

On the British shores.

Unicus, 14. *Unicus.* Shell with nine, slender, glossy, pellucid, white spires, terminating in a fine point, longitudinal ridges undulated, transversely striated; length two-tenths of an inch.

Test. Brit. tab. 12. fig. 2.

First noticed at Sandwich by Mr Boys.

Parvus, 15. *Parvus.* Shell strong, conic, with five or six coarsely ribbed volutions; colour various; outer lip thickened by a rib; length one eighth of an inch.

Brit. Shells, tab. 90.

On the English and Scottish coasts, not uncommon.

Costatus, 16. *Costatus.* Shell strong, white, with four or five whorls; ribs strong, and striated transversely; lip a little expanded; length nearly one-eighth of an inch; breadth one-third of its length.

Test. Brit. tab. 10. fig. 6.

On the English shores not uncommon; also at Dunbar.

Striatus, 17. *Striatus.* Shell pellucid, glossy, white, with six volutions, somewhat rounded and separated by a well defined line; upper part of each volution faintly ribbed, the whole shell regularly striated transversely; mouth marginated; length one-eighth of an inch.

Test. Min. Rar. tab. 2, fig. 49.

Common on the British shores from Devonshire to Zetland.

Bryereus, 18. *Bryereus.* Shell conic, glossy, white, with seven smooth spires, finely costated with about eighteen ribs; outer lip strong, pillar lip replicate, smooth.

Test. Brit. tab. 15, fig. 8.

On the English and Scottish coasts, rare.

Coniferus, 19. *Coniferus.* Shell strong, taper, white, with six volutions, furnished with about twelve undulated ribs, the interstices between them at the top of each volution are formed into small cavities, transversely striated: aperture oval, oblique, strongly marginated; length a quarter of an inch.

Test. Brit. tab. 15, fig. 2.

First observed by Mr Bryer at Weymouth.

Denticulatus, 20. *Denticulatus.* Shell of six volutions, with nine or ten coarse ribs that project at the top of each spire; mouth suborbicular, outer lip thickened by a rib, pillar lip with two small tubercles adjoining the ribs.

Test. Brit. p. 315.

Found with the preceding species, to which it bears a close resemblance.

Decussatus, 21. *Decussatus.* Shell glossy white, with five rounded whorls, well defined by the separating line, strongly striated longitudinally, and crossed with extremely fine striæ; mouth sub-oval, contracted at the upper part; outer lip thin, inner lip not spreading on the columella; length one-eighth of an inch.

Test. Brit. tab. 12, fig. 4.

Found by Mr Montagu in sand from Salcomb bay.

Reticulatus, 22. *Reticulatus.* Shell strong, conic, opake, with six rounded and much raised whorls, strongly reticulated; apex pointed; mouth sub-orbicular, margin thick, inner lip spreading on the columella, and forming a groove or sub-umbilicus; length about one-tenth of an inch.

Test. Min. Rar. tab. 2. fig. 32.

Univalves.

From Seasalter by Mr Walker.

Spiralis, 23. *Spiralis.* Shell pellucid, white, conical, with five volutions; the largest marked with transverse spiral ridges, half way from the base, the rest finely ribbed longitudinally; separating line marked with a fine spiral ridge; pillar lip turns inwards, and forms a subdenticle; length a line.

Test. Brit. tab. 12, fig. 9.

Found by Mr Montagu in Salcomb bay.

Semicostatus, 24. *Semicostatus.* Shell short, conic, white, obtusely pointed, with five rounded whorls, well defined by the separating line, and wrought with faint ribs, and five obsolete transverse striæ on the body whorl; the ribs do not extend to the lower part even of the body whorl; pillar lip a little reflected; length half a line.

Test. Brit. tab. 21, fig. 5.

Found on the coast of Devon by Mr Montagu, and at Dunbar by Mr Laskey.

Strigatus, 25. *Strigatus.* Shell with three transverse ribbed whorls, and a suboval mouth; the colour opake, white.

Test. Min. Rar. tab. 2, fig. 38.

From Seasalter by Mr Walker.

Carinatulus, 26. *Carinatulus.* Shell opake, white, with seven taper longitudinally ribbed spires; mouth contracted, marginated.

Test. Min. Rar. tab. 2, fig. 44.

Found at Sandwich by Mr Walker, rare.

Albulus, 27. *Albulus.* Shell opake, with five longitudinal ribbed whorls; aperture roundish, not marginated.

Lin. Trans. vol. iii. tab. 13, fig. 17, 18.

Found on the coast of Pembrokeshire by Mr Adam.

Subelegans, 28. *Subelegans.* Shell with six whorls, striated spirally; the ribs remote; aperture oval.

Lin. *Trans.* vol. iii. tab. 13. fig. 31, 32.

Found with the preceding species.

Subarcuatus, 29. *Subarcuatus.* Shell pellucid, white, with ten longitudinal ribbed whorls, a little curved towards the point.

Lin. *Trans.* vol. iii. tab. 13. fig. 27. 28.

Found with the preceding species.

Marginatus, 30. *Marginatus.* Shell white, subcylindric, strong with six ribbed whorls, finely striated in a spiral direction; pillar lip thickened, outer lip extremely thick and rounded by a rib at the back; length three eighths of an inch.

Mem. Wernerian Soc. vol. i. tab. 8. fig. 13.

Found by Mr Laskey at Dunbar.

Indistinctus, 31. *Indistinctus.* Shell subcylindric, glossy white with six spires, nearly flat, but well defined by the separating line, striated longitudinally and transversely; pillar lip smooth, and a little spread upon the columella; length one-tenth of an inch.

Test. Brit. p. 129.

Described by Mr Montagu from the Boysian cabinet.

Simillimus, 32. *Simillimus.* Shell slender, white, with eight or nine spires furnished with 14 ribs standing in the line of the shell, bare and destitute of striæ; length three-eighths of an inch.

Test. Brit. p. 136.

Found by Mr Laskey on the shores of Jura.

D. Shells furnished with a pillar cavity, or umbilicus.

Elegans, 33. *Elegans.* Shell with five ventricose whorls, marked with strong spiral stria crossed by finer longitudinal ones; mouth orbicular, projecting on the pillar lip; margin faintly marked by the striæ; behind the pillar lip a sub-umbilicus; operculum spirally striated; length five-eighths of an inch; breadth three-eighths.

Brit. Zool. tab. 82. fig. 110.

Found plentifully in England under moss and at the roots of ferns.

Vinctus, 34. *Vinctus.* Shell smooth, conic, with six rounded volutions, of a rufous horn-colour; the lower spire marked with four or five chesnut coloured bands, with a broad space between the three lower and the upper; outer lip very thin, inner lip thick; pillar cavity small; length three-eighths of an inch.

Test. Brit. tab. 20. fig. 3.

Found by Mr Montagu in Salcomb bay.

Auricularis, 35. *Auricularis.* Shell horn-coloured with five rounded volutions deeply divided by the separating line; mouth sub-oval, outer lip thin, inner lip much reflected upon the body; length three-eighths of an inch.

Test. Brit. p. 308.

Found by Mr Montagu on the shore near Southampton. We have likewise observed it at Leith shore.

Canalis, 36. *Canalis.* Shell horn coloured with fine smooth volutions, the lower one large in proportion to the rest, pointed; mouth sub-orbicular, outer lip extremely thin, pillar lip broad, white, with a groove terminating in a pillar cavity or umbilicus; minutely sub-reticulated.

Test. Brit. tab. 12. fig. 11.

On the British shores frequent.

Subumbilicatus, 37. *Subumbilicatus.* Shell smooth, glossy, conic, yellowish white, with five tumid volutions, the first occupying above half the shell, rather obtuse, mouth oval, outer lip even, inner lip a little reflexed, forming a sulcus or sub-umbilicus; length one-eighth of an inch.

Pulteney's *Dorset.* tab. 18. fig. 12.

Found by Mr Bryer on the shore of Weymouth; we have likewise observed it in great plenty at St Andrew's.

Pallidus, 38. *Pallidus.* Shell smooth, white, slender with seven spires, volutions not much raised, but well defined by the separating line; outer lip arcuated; a faint duplicature on the pillar lip, with a small umbilicus formed by its reflexion; length one-eighth of an inch.

Test. Brit. tab. 21. fig. 4.

Found at Salcomb bay by Mr Montagu.

Quadrifasciatus, 39. *Quadrifasciatus.* Shell strong, smooth with four volutions, the first whorl sub-carinated at the lower edge, occupying more than half of the shell; colour white, usually marked with four faint brown bands on the body, and sometimes two on the second spire, minutely sub-reticulated; mouth sub-orbicular, thickened within, but sloped to a sharp edge on the outer lip, pillar lip grooved umbilicated; length about a quarter of an inch.

Test. Brit. tab. 20. fig. 7.

Found on the British shores, from Devonshire to Zetland.

Disjunctus, 40. *Disjunctus.* Shell slender, white, perfectly smooth with six rounded volutions, divided by a broad and deep line of separation, the bottom of which is flat or a little concave; pillar lip reflected, beneath which is a small umbilicus; length scarcely a quarter of an inch.

Mem. Wernerian Soc. vol. i. tab. 8. fig. 3.

Found by Mr Laskey on Belton sands near Dunbar.

Calcar, 41. *Calcar.* Shell somewhat compressed, with four whorls, the superior ones depressed, forming a flat summit; round the larger and part of the second whorls, are large smooth lanceolate spines, radiating in straight lines from the shell, and thirteen in number, base con-

Univalves. vex, umbilicated; colour pale pink, diameter upwards of a quarter of an inch.

Test. Brit. tab. 29. fig. 3.

Found by Mr Laskey on the shore of Iona.

E. Shells imperforated at the base of the columella.

Crassior, 42. *Crassior.* Shell yellowish white, thick, opake, conical, with five rounded whorls, divided by a deep depression, and terminating in a fine point; pillar lip wrinkled; length half an inch.

Test. Brit. tab. 20. fig. 1.
Brit. Shells, tab. 178. fig. 4.

Live shells are covered with a thin light yellowish brown epidermis, which sometimes rises into longitudinal ridges, beneath which a few obsolete spiral striæ are observed on the body whorl; common on the British shores.

Cimex, 43. *Cimex.* Shell with four strong, conical, reticulated, white volutions; apex obtuse; margin of the mouth thick, outer lip crenated on the inside; length one-eighth of an inch.

Brit. Shells, tab. 2. fig. 1.

On the English shores rare, and Mr Laskey has only once met with it near Dunbar.

Calathiscus, 44. *Calathiscus.* Shell conic, with six brown spires, elegantly tuberculated in spiral lines; on the body whorl are eight series of tubercles, on the second four rows, and afterwards one less in each succeeding superior volution till wholly lost at the apex; outer lip denticulated within; length a quarter of an inch.

Test. Brit. tab. 30. fig. 5.

Found by Mr Laskey on the island of Jura.

Ventrosus, 45. *Ventrosus.* Shell smooth, glossy, thin, with six ventricose whorls of a light pellucid horn colour, aperture suborbicular, closed by a thin wrinkled corneus operculum, margin almost entire the whole way round; length one-eighth of an inch.

Test. Brit. tab. 10. fig. 13.

On the coast of Kent frequent.

Ulvæ, 46. *Ulvæ.* Shell with seven smooth volutions, nearly flat, separated by a small line, apex moderately pointed; inner lip reflected on the columella, forming a slight depression behind, but no umbilicus; about three-eighths in length.

Brit. Zool. tab. 86. fig. 120.

On the British shores frequent.

Pullus 47. *Pullus.* Shell with four rounded glossy volutions, the first large, colour various; mouth sub-orbicular, large; length three-eighths of an inch.

Brit. Shells. tab. 2. fig. 2.

On the English shores not uncommon.

Punctura, 48. *Punctura.* Shell with six very glossy rounded volutions, rather taper in shape, and finely reticulated; colour transparent yellowish white; mouth suborbicular; length one-tenth of an inch.

Test. Brit. tab. 12. fig. 5.

On the British shores not uncommon.

Ruber, 49. *Ruber.* Shell with fine, smooth, pellucid, glossy, reddish brown volutions, rounded, and divided by a fine separating; aperture sub-orbicular, a little reflected on the pillar; length one-eighth of an inch.

Lin. Trans. vol. iii. tab. 13. fig. 21, 22.

Found by Mr Adam at Pembroke, and by Mr Montagu in Cornwall; we have observed it in Zetland.

Vitreus, 50. *Vitreus.* Shell with four very rounded, white, smooth, subcylindric volutions; mouth sub-oval, contracted at the upper end; outer lip thin, inner lip a little thickened; length one-eighth of an inch.

Test. Brit. tab. 12. fig. 3.

Found by Mr Montagu at Whitsand bay in Cornwall. Univalves.

51. *Nivosus.* Shell smooth, glossy, white, rather slender, and tapering to an obtuse point, volutions six, much rounded; length nearly a line. Nivosus,

Test. Brit. p. 326.

Found on the coast of Devon by Mr Montagu.

52. *Unifasciatus.* Shell smooth, conic, white, with one, and sometimes two bands of purplish brown on the body, one on the second spire, and sometimes also on the third; whorls five, a little raised; outer lip thin and turning outwards, inner lip spreading on the columella; length one-eighth of an inch. Unifasciatus,

Test. Brit. tab. 20. fig. 6.

On the English coast rare; found also at Dunbar by Mr Laskey.

53. *Cingillus.* Shell conical, pellucid, with six whorls, marked with alternate bands of horn-colour and chesnut brown, three of each on the body, and two on the other spires, which are obscurely striated; apex brown, aperture sub-oval, contracted at the upper part; length one-eighth of an inch. Cingillus,

Test. Brit. tab. 12. fig. 7.

On the English coast common.

54. *Interruptus.* Shell pellucid, glossy white, marked with interrupted longitudinal ochreaceous streaks, most conspicuous on the two larger spires; whorls five, not much raised; mouth sub-orbicular, inner lip reflected; length one-eighth of an inch. Interruptus,

Test. Brit. tab. 20. fig. 8.
British Shells, tab. 178. fig. 2.

Common to the British shores, from Devonshire to Zetland.

55. *Retiformis.* Shell white, opake, with four tumid reticulated spires, with an oval aperture. Retiformis,

Test. Min. Rar. tab. 2. fig. 37.

From Sandwich, Mr Walker.

56. *Fuscus.* Shell brown, opake, spires fine, striated, aperture suboval. Fuscus.

Test. Min. Rar. tab. 2. fig. 42.

From Bysing wood near Faversham, rare, Mr Walker.

57. *Rivulus.* Shell white, opake, striated; whorls four; mouth oval, marginated. Rivulus,

Test. Min. Rar. tab. 2. fig.

From a stream near Faversham. Mr Walker.

58. *Fulgidus.* Shell subconic, pellucid, smooth, variegated with white and bronze, usually in bands; whorls three, the first very large, mouth suborbicular, margin attenuated; length half a line. Fulgidus,

Test. Brit. p. 332.

Found by Mr Montagu in sand from Whitsand-bay, Cornwall.

59. *Scriptus.* Shell smooth, with three whorls, marked with brown lines resembling characters; aperture roundish. Scriptus,

Lin. Trans. vol. 3. tab. 13. fig. 11, 12.

Found by Mr Adams on the coast of Pembroke.

60. *Divisus.* Shell pellucid, white, with four whorls each divided into two parts, the upper one smooth, the lower one spirally striate; aperture suboval. Divisus,

Found along with the last.

61. *Subrufus.* Shell smooth, with fine whorls, somewhat angular above; opake; dull red; the upper part of each whorl marked with a white transverse band. Subrufus,

Lin. Trans. vol. v. tab. 1. fig. 18, 19.

Found with the two preceding species.

64. *Ziczac.* Shell conic, with six substriated, white or purplish white spires, marked with equidistant, longitudinal, undulated, purple lines; apex acute; base Ziczac.

Univalves.

sub-carinated; mouth subovate; length half an inch; breadth a quarter.

Lin. Trans. vol. viii. tab. 4. fig. 14.

Found by Lady Wilson near Sunderland, in the county of Durham.

Semistriatus.

63. *Semistriatus.* Shell thick, conic, white, with six rounded spires; base of the shell, as far as the upper angle of the mouth, finely striated spirally; the same is observable on the upper and lower parts of the other volutions; mouth angulated at the interior end; pillar lip thickened on the columella; length one eighth of an inch.

Test. Brit. Sup. p. 136.

Found by Mr Montagu on the coast of South Devon.

Genus XIV. Odostomia.

XIV. Odostomia.

Shell spiral, produced, mouth contracted, subangular, generally distinct from the body whorl, and furnished with teeth.

Obs. The shells which we have formed into the present genus were included by Linnæus in the turreted division of his genus *turbo.* They were thus associated with species to which they bear no affinity in habit, and from which they differ in character. By far the greater number inhabit the land, and are found under stones, on rocks, and among moss. The genus admits of a twofold sub-division.

A. Spires dextral.

Muscorum,

1. *Muscorum.* Shell smooth, glossy, horn-coloured, sub-cylindric, with six spires; apex obtuse; mouth suborbicular marginated; the margin white, a little reflected; pillar lip, furnished with a single tooth; length about the eighth of an inch.

Test. Brit. tab. 22. fig. 3. T. muscorum.

A very common species at the roots of trees and under stones.

Sexdentata,

2. *Sexdentata.* Shell smooth, brown, horn-coloured, with five spires, somewhat rounded; aperture sub-orbicular; outer lip uneven, sub-angulated, usually furnished with six teeth, four on the outer lip and two on the inner; length a line.

Test. Brit. tab. 12. fig. 8.

In marshes in England on the Iris pseudacorus.

Tridens,

3. *Tridens.* Shell sub-cylindrical, smooth, glossy, of a light brown colour; volutions seven; scarcely raised; apex obtuse; mouth small and curved; outer lip furnished with one tooth on the margin; pillar lip a little reflected, with two long and two short teeth alternately; length a quarter of an inch.

Mem. Wernerian Soc. vol. i. tab. 8. fig. 11.

In England rare. Mr Laskey found it in Caroline park near Edinburgh,

Carychium,

4. *Carychium.* Shell glossy, pellucid, white, with five longitudinally striated whorls, rounded, and well defined by the separating line; mouth suboval, contracted, marginated; outer lip thickened inwards by a knob; pillar lip furnished with two teeth, and sometimes the rudiments of a third above the other two; length about a line.

Test. Brit. tab. 22. fig. 2.

Common in woods and mossy banks in England and Scotland.

Juniperi,

5. *Juniperi.* Shell sub-cylindric, opake, brown, with nine spires striated longitudinally oblique; the four first volutions are cylindrical, the rest taper to an obtuse apex; mouth sub-orbicular, marginated, reflected, white, with three teeth on the outer lip, and four on the columella; a cavity behind the pillar lip; length upwards of a quarter of an inch.

Test. Brit. tab. 12. fig. 12.

Found by Mr Montague and Mr Bryer in England. Mr Laskey has found it at Dunbar. It inhabits the roots of juniper bushes.

Interstincta,

6. *Interstincta.* Shell glossy, white, taper, with five rather flat, but finely ribbed volutions; mouth suboval; pillar lip a little reflected, with a single small tooth; length about a line.

Test. Brit. tab. 12. fig. 10.

A rare shell; found by Mr Montagu in sand from Bigberry-bay in Devonshire.

Unidentata,

7. *Unidentata.* Shell strong, conic, smooth, glossy, subpellucid, volutions six, not much raised; aperture sub-oval; outer lip plain; columella furnished near the middle with one tooth; length two-tenths of an inch.

Test. Brit. p. 324.

Found in Salcomb bay adhering to the *Pecten maximus.*

Plicata,

8. *Plicata.* Shell smooth, glossy, subpellucid, white, with six rather slender spires, terminating in an obtuse apex; volutions nearly flat; aperture contracted a little to an angle on the upper part; outer lip even; inner lip furnished with a single toothlike fold.

Test. Brit. tab. 21. fig. 2.

Found in sand from Salcomb bay by Mr Montagu.

Sandvicensis,

9. *Sandvicensis.* Shell pellucid, white, spires three, elegantly reticulated; aperture oval; one tooth.

Test. Min. Rar. tab. 2. fig. 55.

From Sandwich. Mr Walker.

Insculpta,

10. *Insculpta.* Shell pellucid, white and taper, with five or six moderately convex whorls, striated spirally; apex obtusely pointed; aperture subovate; pillar lip, with a faint duplicature forming a sub-umbilicus, and furnished with a small tooth; length one-eighth of an inch.

Test. Brit. Sup. p. 129.

A rare shell, found on the coast of Devon by Mr Montagu.

B. Spires Sinistral.

Perversa,

11. *Perversa.* Shell with eight or nine regular tapering spires, obsoletely striated; volutions a little rounded and divided by a deep separating line; mouth suborbicular; outer lip a little reflected; pillar lip not detached, edges white, thin, at the upper angle a toothlike knob; length nearly a quarter of an inch.

Test. Brit. tab. 11. fig. 12.

Animal dusky above, light beneath; tentacula four, short, cylindric, clavate, furnished with eyes at the tips of the longest. Found on rocks, trees, and moss, in England and Scotland common.

Nigricans,

12. *Nigricans.* Shell taper, swelling a little in the middle, and marked with fine longitudinal striæ; volutions rather flat, but well defined and twelve in number; mouth compressed on the outer angle near to the body; pillar lip furnished with two teeth, and perfectly detached from the body whorl; at the back of the lower volution, behind the mouth, is a prominent ridge and a depression.

Test. Brit. tab. 11. fig. 7.—Turbo-bidens.

Animal dusky; tentacula four, short, cylindric, clavate; the two longest furnished with eyes at their tips. A very common shell on rocks, trees, and moss in both kingdoms.

Laminata,

13. *Laminata.* Shell smooth, glossy, pellucid, with ten spires; thickest in the middle, tapering from thence to a small round point; volutions a little raised; mouth

Univalves. compressed at the upper outer margin, where it joins the body; lip white; pillar lip furnished with two teeth, and deep within the mouth are three or four prominent ridges; length nearly three quarters of an inch.

Test. Brit. tab. 11. fig. 4.

Animal light brown, paler beneath, tentacula and eyes resembling the preceding species.

Biplicata, 14. *Biplicata.* Shell with twelve or thirteen taper striated spires; mouth compressed at the upper part, and slightly at the extremity; lips thick, white, reflected; margin connected all round; pillar lip prominent and detached, furnished with two white approximating teeth-like laminæ; length three quarters of an inch.

Labiata, 15. *Labiata.* Shell light brown, opake, taper, with nine spires, wrought with strong and regular striæ the whole length of the shell; volutions flat; mouth suborbicular with a sinus at the upper end, and furnished with two teeth-like laminæ on the inner lip; margin very broad, thick, and white; pillar lip a little detached from the body whorl; length five eighths of an inch.

Test. Brit. tab. 11. fig. 6.

Found by Mr Swainson in ozier grounds at Battersea, Surry.

Vertigo. 16. *Vertigo.* Shell oval, opake, brown, with five faintly striated spires; apex obtuse; aperture sub-triangular, sub-marginated, indented, usually furnished with three white teeth, two on the columella, and one on the exterior lip opposite; length half a line.

Test. Brit. tab. 12. fig. 6.

Tentacula two, with eyes at their tips. Found by Mr Boys and Mr Montagu on old ivy walls.

Genus XV. Lymnæa.

XV. Lymnæa. *Shell ovate conical, mouth entire, longitudinally oblong, the right lip joined to the left at the base and folding back on the pillar.*

Obs. The genus Helix of Linnæus is unquestionably a confused one. The discoide species of that genus we have already considered under the genus Planorbis, and the turreted species from the present genus, which was constituted by Lamarck, and of which Latreille gives the following definition: " *Coquille oblongue, presque turriculée; l'ouverture entière, plus longue que large; partie inférieure du bord droit remontant en rentrant dans l'ouverture, et formant sur la columelle un pli très oblique.*"

Stagnalis, 1. *Stagnalis.* Shell thin, translucent, with six or seven spires; the first very large, the others small and tapering to a fine point; slightly wrinkled longitudinally; outer lip thin, pillar lip thickened. Length one inch and three quarters; breadth one inch.

Brit. Zool. tab. 86. fig. 136. Helix.
Test. Brit. tab. 16. fig. 8.

This species is the largest of the British fresh water univalves. It inhabits slow running rivers and stagnant waters.

Fragilis, 2. *Fragilis.* Shell thin, translucent, horn-coloured; slender in the superior volutions; whorls little raised.

Test. Brit. tab. 16. fig. 7.

Found by Mr Montagu in the canal between Chippenham and Laycock in Wiltshire.

Palustris, 3. *Palustris.* Shell horn-coloured, with six spires tapering to a sharp point; whorls slightly wrinkled longitudinally, sometimes marked with irregular transverse ridges; length an inch, breadth three eighths.

Test. Brit. tab. 16. fig. 10.
Brit. Shells. tab. 175. fig. 1, 2.

In ditches and swamps in England. It has been observed in Duddingstone Loch, near Edinburgh, by Dr Leach. Univalves.

4. *Fossaria.* Shell thin, horn-coloured, tapering, with five or six spires; whorls rounded, divided by a well-defined separating line; length three eighths of an inch; breadth about one third of its length. Fossaria,

Test. Brit. tab. 16. fig. 9.

Animal dusky; tentacula two, somewhat compressed, short; eyes on the head at the base of the tentacula. In shallow pools exposed to the sun and in muddy ditches. Common in England and Scotland.

5. *Putris.* Shell with four spires, the first very large, the others small, apex fine pointed; mouth large oval, three fourths of the length of the shell; usually covered with a dusky brown epidermis; length one inch, breadth five-eighths. Putris,

Brit. Zool. tab. 86. fig. 137.
Test. Brit. tab. 16. fig. 3. Helix peregra.

The animal is an aquatic species of a yellowish colour, with two broad flat pyramidal tentacula, eyes at the base of the tentacula beneath. Common in Britain in almost every ditch.

6. *Auricularia.* Shell thin, sub-pellucid, with four spires, the first extremely large occupying almost the whole of the shell; apex pointed; body whorl longitudinally wrinkled; outer lip much extended, thin, and sub-reflected; length about an inch, breadth three quarters of an inch. Auricularia,

Brit. Zool. tab. 86. fig. 138. Helix auricularis.
Brit. Shells. tab. 51. fig. 1.
Test. Brit. tab. 16. fig. 2.

Tentacula of the animal broad, flat, conic, speckled with brighter yellow. Found in stagnant pools in England; common in Scotland. Somewhat rare.

The variety of this shell termed *Helix limosa, Test. Brit.* tab. 16, fig. 1, is only the young of this species. The first volution is less ventricose, and thinner, and the mouth not so patulous; but it has no character to entitle it to be considered as distinct. The *Helix limosa* of Linnæus is essentially different.

7. *Succinea.* Shell very thin, pellucid, glossy, reddish-yellow, with three spires, the first very large, wrinkled longitudinally; mouth oval, occupying two-thirds of the shell; outer lip submembranaceous; pillar lip slightly thickened; length three-quarters of an inch. Succinea,

Test. Brit. tab. 16, fig. 4, *Helix putris.*

The animal of this shell has four tentacula. This species resides upon the leaves and stalks of subaquatic plants. It is a very common species in Britain.

8. *Lutea.* Shell sub-oval, sub-pellucid, with about three whorls, the first very large; mouth oval, expanded; length nearly half an inch; breadth rather more than a quarter. Lutea,

Test. Brit. tab. 16, fig. 6.

It is exceedingly doubtful, whether this is a land or a sea shell. Mr Montagu has found it on the open part of the coast of South Devon.

9. *Detrita.* Shell conic, sub-pellucid, with six whorls, not much elevated, but a little rounded, and separated by a well defined line; colour white, glossy; a little wrinkled longitudinally, and commonly marked with one ferruginous band round the middle of the body; mouth oval; length three quarters of an inch; breadth three-eighths. Detrita,

Test. Brit. tab. 11, fig. 1.

Found by Mr Bryer in a pool near Weymouth, and in a stream near Dorchester.

10. *Vivipara.* Shell with six ventricose spires, separated by a deep depressed line; shape sub-conic, sud- Vivipara,

Univalves.

denly terminating in a small point; colour olive green, with three brownish bands on the body; aperture suborbicular; operculum corneus, pellucid, and wrinkled concentrically; length rarely an inch and a half.

Brit. Zool. tab. 84, fig. 132.

Brit. Shells, tab. 87.

The animal is dusky black, thickly speckled with orange-yellow; the snout is produced. This species is viviparous. Found in the Thames, and streams communicating with that river; also in the Stour, Dorsetshire.

Fontinalis,

11. *Fontinalis.* Shell thin, sub-pellucid; horn-coloured, with four or five much rounded, prominent, smooth whorls; apex obtuse; aperture perfectly orbicular; lips thin; inner lip slightly attached to the body whorl; pillar cavity deep; operculum corneus with a small knob in the centre; length and breadth nearly the same, rarely exceeding a quarter of an inch.

Brit. Shells, tab. 102.

The animal has two tentacula placed as usual, another on the right side, and on the middle of the hind head a pellucid plumose appendage. Common in England and Scotland in deep pools and stagnant waters. This species has changed its place in the system of conchology repeatedly, having, in succession, been placed in the genera *Helix, Nerita, Trochus,* and *Turbo;* thus intimating its remote connection with all of them.

Tentaculata,

12. *Tentaculata.* Shell smooth, conic; horn-coloured, with six rounded spires, divided by a deep separating line; apex pointed; mouth sub-orbicular, contracted at the upper part; outer lip moderately strong; operculum testaceous, concentrically wrinkled; length half an inch; breadth a quarter.

Brit. Zool. tab. 86, fig. 140, *Helix tentaculata,* &c.

Brit. Shells, tab. 93.

Animal pale, with two very long slender setaceous tentacula, which are continually in motion; at the base of these are situated the eyes. It is a common species in England, in most slow rivers and stagnant waters.

Elegantissima,

13. *Elegantissima.* Shell with thirteen flat spires, long, taper; volutions cut into regular equidistant furrows; aperture a little angulated at the upper and lower parts; length about a quarter of an inch.

Test. Brit. tab. 10, fig. 2.

On the English coast not uncommon; also found at Dunbar by Mr Laskey.

Lubrica,

14. *Lubrica.* Shell smooth, glossy, pellucid, horn coloured, with six spires very little rounded, and not much raised; apex rather obtuse; mouth oval; outer lip rather thick; length a quarter of an inch; breadth one-third of its length.

Test. Brit. tab. 22, fig. 6.

Lin. Trans. vol. viii. tab. 5, fig. 11.

This shell is very easily distinguished when alive by its extreme glossiness. It resides in moist woods, among moss, or under decayed wood. It is a very common British shell.

Obscura,

15. *Obscura.* Shell sub-cylindric, opake, brown, with about seven spires, a little rounded, and well defined by the separating line; whorls wrinkled longitudinally; mouth oval, marginated white; length three-eighths of an inch; breadth more than one-third of its length.

Test. Brit. tab. 22, fig. 5.

Lin. Trans. vol. viii. tab. 5, fig. 11.

This animal inhabits the same places with the preceding. We have likewise observed it, particularly on Arthur's Seat near Edinburgh, on the sides of stones, and in the winter under them. A British shell not uncommon.

1

Univalves.

Subcylindrica,

16. *Subcylindrica.* Shell cylindric, imperforated, subpellucid, light chesnut coloured, with four spires, terminating in an obtuse, smooth, button-like whorl, as if truncated; the volutions a little rounded, and well defined by the separating line; furnished with close set rib-like longitudinal striæ; mouth oval; length a quarter of an inch.

Pult. H. Dorset. tab. 19, fig. 8.

According to Dr Pulteney, this shell is found on water plants in rivers and ponds in Dorsetshire. Suspicions are generally entertained, that the Doctor, in respect to this shell, was deceived. We have found his shell in the Frith of Forth, but still not in a situation to enable us to determine with absolute certainty, whether it is a sea or land species. It was found, along with fragments of sea-shells, in the cavity of a dead *Echinus lacunosus.*

Fasciata,

17. *Fasciata.* Shell thin, taper, with nine spires, a little rounded, but not much raised; apex moderately pointed; whorls wrinkled across; colour white, longitudinally striated with brown; length nearly three quarters of an inch; breadth a quarter.

Brit. Zool. tab. 82, fig. 119.

Brit. Shells, tab. 18.

Found in great profusion in some places near the south coast of England, on sandy soil. It has likewise been found in Scotland by Mr Hansen at Iona.

Lackhamensis,

18. *Lackhamensis.* Shell sub-pellucid, of a dull rusty brown colour; wrinkled longitudinally; volutions seven, nearly flat, but well defined by the separating line; the three or four first whorls sub-cylindrical, the rest more suddenly taper to an obtuse point; mouth marginated; length five-eighths of an inch; breadth a quarter.

Test. Brit. tab. 11, fig. 3.

Found by Mr Montagu in a moist wood at Lackham in Wiltshire.

Octona,

19. *Octona.* Shell with eight whorls; mouth nearly orbicular; about the size of a grain of rye, and of a horn-colour.

Pult. H. Dorset. tab. 18, fig. 8.

Lin. Trans. vol. viii. fig. 10.

This species is inserted solely on Dr Pulteney's authority. " He says, " I have only found it dead, and in a bleached state, but otherwise perfect."

Octanfracta,

20. *Octanfracta.* Shell pellucid, horn-coloured, with seven or eight smooth or very finely wrinkled slender spires, gradually tapering to a fine point; the volutions are rather flat, but well defined by the separating line; mouth oval; outer-lip very thin; length about five-eighths, breadth two-tenths of an inch.

Test. Brit. tab. 11. fig. 8. *Helix octanfracta.*

This shell is probably the Helix octana of Pennant. It is rather a rare English shell; and, in Scotland, we have only observed it in ditches, in the upland parts of Linlithgowshire. It occasionally, as we have noticed, climbs up the stalks and leaves of aquatic plants, and, in being thus amphibious, resembles the *L. fossaria.*

Polita,

21. *Polita.* Shell strong white, glossy, smooth; volutions from nine to thirteen, flat and scarcely separated; slender and gradually tapering to a fine point; aperture oval, and forming a contraction at the upper end; outer lip rather thick; length five-eighths of an inch, breadth two-tenths.

Brit. Shells, tab. 177.

Found sparingly on the western coasts of England. Mr Laskey has found it at Dunbar.

Decussata,

22. *Decussata.* Shell slender, white, with eight or nine spires tapering to a fine point; whorls striated

Univalves. strongly in a longitudinal direction; mouth narrow, sub-oval, contracted at both ends; outer lip somewhat expanded, and a little thickened at the back; length three-tenths of an inch, breadth one-tenth.

Test. Brit. tab. 15. fig. 7.

Found by Mr Bryer on the shore between Weymouth and Portland Island.

Labiosa, 22. *Labiosa.* Shell sub-conic, sub-pellucid, with seven or eight flattish spires ending in a fine point, and furnished with from fifteen to eighteen faint ribs on the three largest whorls; the superior volutions smooth; lips thickened, within white; the back of the outer lip a little gibbose; length rather more than a quarter of an inch, breadth nearly one half of its length.

Test. Brit. tab. 13. fig. 7.

A shell not uncommon in England. Has been found in Scotland, on the coast at Dunbar, by Mr Laskey.

Subulata, 23. *Subulata.* Shell subulate, smooth, glossy, with about ten scarcely defined whorls; colour white, marked with two faint yellowish lines, which follow the spiral turn of the shell, but become obsolete towards the apex; mouth narrow, contracted at the interior angle; length about three-quarters of an inch.

Brit. Shells, tab. 172.

First noticed by Da Costa, from Exmouth in Devonshire; Mr Donovan received it from Weymouth; and Mr Laskey found it at Dunbar.

Petræa. 24. *Petræa.* Shell strong, conic, opake, with five spires, occupying nearly two-thirds of the length of the shell, and irregularly wrinkled; mouth lunated; outer lip considerably projecting, operculum corneus; length about a quarter of an inch, breadth two-tenths of an inch.

Test. Brit. p. 403.

Found on the coast of Devon and Dorset by Mr Montagu.

Family II. GLOBOSE.

The shells which this family includes are, in form, somewhat orbicular. The first, or body whorl, is large; the remaining volutions decrease in size to the apex rather suddenly. The apex is seldom much produced. In consequence of this shape of the whorls, the shell is broader than it is long. The mouth is entire, and of a roundish form. The common garden slug (*Helix aspersa*) may be considered as the type of the family. At present we shall consider the British species under the three following genera: Helix, Nerita, and Trochus.

Genus XVI. Helix.

XVI. Helix. *Shell subglobose, with a convex spire; the opening entire, wider than long, and diminished in its upper part by the projection of the last turn but one of the spire.*

Obs. The shells of this genus, with a few exceptions, are inhabitants of the land. They are usually translucent and brittle. The species of the genus admit of distribution into two subdivisions. The first will contain those shells which are furnished with a pillar cavity, or in which the base of the pillar is perforated. The second will include those in which the base of the pillar is closed. The land shells of this subdivision have the base of the pillar perforated in the earlier stages of their growth, and until the margin of the mouth is formed.

A. Base perforated.

Pomatia, 1. *Pomatia.* Shell sub-globose, translucent, yellowish brown with five rounded whorls wrinkled longitudinally; mouth semilunated; margin a little thickened; inner lip much reflected over the pillar cavity; diameter about two inches.

Brit. Zool. tab. 84. fig. 128.

The name of this species is derived, not from any thing relating to an orchard, but from Πωμα, an operculum, it having a very strong one. It is not indigenous, or originally a native of Britain, but is a naturalized species. It was first introduced into England by a Mr Howard about the middle of the 16th century. In the southern counties it is very common. We have likewise observed them in the garden of Patrick Neill, Esq. at Canonmills, near Edinburgh, into which they were lately introduced. They were a favourite dish among the Romans.

Virgata, 2. *Virgata.* Shell with six rounded volutions considerably produced. Colour white tinged with black, with one dark purplish brown band on the middle of the body; mouth lunated, lip thin, pale purplish brown, with a white thread-like elevation round the margin; pillar cavity deep; length generally half an inch.

Test. Brit. tab. 24. fig. 1.

Brit Shells. tab. 65. *H. Zonaria.*

Inhabits dry banks and sandy soils in various parts of England.

Cingenda, 3. *Cingenda.* Shell sub-pellucid, with five whorls; the larger ones are a little angulated at the top, apex dark, obtuse and depressed; colour yellowish white, with several small bands of chesnut running spirally up the shell; the base has generally one circular band; minutely striated longitudinally and transversely; pillar cavity very small; breadth at the base three quarters of an inch; height half an inch.

Brit. Zool. tab. 85. fig. 133. *H. Zonaria.*

Lin. Trans. vol. viii. tab. 5. fig. 6.

Found by Mr Montagu at Lenby in South Wales, and Mr Racket has found it near St Ives in Cornwall. It lives upon maritime plants.

Rufescens, 4. *Rufescens.* Shell rufous with six whorls, well separated, a little rounded wrinkled across; edge of the lower volution sub-carinated; mouth lunated; outer lip thin, and a little reflected at the lower angle; pillar cavity large and deep; diameter at the base half an inch.

Brit. Shells. tab. 57. fig. 1. 1.

Test. Brit. tab. 23. fig. 2.

This shell, when young, is thickly covered with short hairs seated on the epidermis. It inhabits moist woods and under stones. It is very common in England and Scotland.

Cantiana, 5. *Cantiana.* Shell with six volutions, rounded, well defined by the separating line; mouth lunated; margin a little thickened, inner lip reflected; pillar cavity narrow but deep. Diameter at the base above three quarters of an inch; height half an inch.

Brit. Shells. tab. 157. fig. 2. 2. *H. pallida.*

This species somewhat resembles the preceding; it is however larger, of a lighter colour, and has a smaller pillar cavity. It is found in meadows and hedges in Kent, Surry, and Dorset.

Hispida, 6. *Hispida.* Shell sub-globose, thin, fragile, with five rounded volutions of a light horn-colour, covered with fine thick-set short whitish hairs; apex flattened; mouth lunated; inner lip a little reflected; pillar cavity small, round; diameter about a quarter of an inch.

Test. Brit. tab. 23. fig. 3.

Found among moss in England, not uncommon. We have found it frequently in Scotland The shape of

Univalves. the pillar cavity, and the reflection of the pillar lip, distinguish it from the *H. rufescens*, with the young of which it has frequently been confounded.

Lucida, 7. *Lucida.* Shell smooth, glossy, horn-coloured, with five or six volutions, the lower one rounded, the rest almost flat; mouth lunated, margin thin; pillar cavity large and deep. Diameter usually three eighths of an inch.

Test. Brit. tab. 23. fig. 4.

Lin. Trans. vol. viii. tab. 5. fig. 7. *H. nitius.*

A common British shell. It is likewise very common in Zetland. It frequents moss, old walls and stones.

Trochiformis, 8. *Trochiformis.* Shell thin, smooth, glossy, horn-coloured, with six rounded volutions, strongly divided by the separating line; apex considerably produced; base a little rounded; mouth sub-lunated, transversely compressed; lip attenuated; pillar cavity small; diameter about one eighth of an inch.

Test. Brit. tab. 11. fig. 9.

This is a rare shell. Found in Wiltshire and Devonshire by Mr Montagu.

Lacuna, 9. *Lacuna.* Shell thin, sub-globose, of a light horn-colour, with four tumid smooth spires, the first large, the two uppermost very small, and placed somewhat laterally; mouth large, outer lip thin, pillar lip thick, white, grooved, with a long canal which ends in a small but deep pillar cavity. Diameter about a quarter of an inch.

Test. Brit. tab. 13. fig. 6.

Found by Mr Montagu on the shore, about high-water mark, at Southampton, and sparingly on the Devonshire coast. Mr Laskey has likewise found it at Dunbar.

Spinulosa, 10. *Spinulosa.* Shell sub-pellucid, with five rounded volutions well defined by the separating line, furnished with regular membranaceous striæ that rise into fine hair-like spines, particularly round the middle of each volution; apex considerably produced; mouth semilunated; pillar cavity small; diameter about one-tenth of an inch.

Test. Brit. tab. 11. fig. 10.

This shell is rather a local species. It has been found in several places in England. We have found it in Scotland at Tarvet mill near Cupar, Fifeshire, among moss.

Caperata, 11. *Caperata.* Shell sub-pellucid, somewhat compressed, with six whorls, furnished with strong, regular, close-set, longitudinal striæ. On the upper part of the body whorl there is usually a brown belt; mouth lunated; lip thin, not reflected; pillar cavity large and deep; diameter at the base about half an inch.

Test. Brit. tab. 11. fig. 11.

In England among dry short pasture, frequent. Found likewise at Musselburgh by Mr Laskey.

Radiata, 12. *Radiata.* Shell compressed, sub-carinated, rayed with chesnut; whorls six, not much raised, but well defined by the separating line, and strongly marked with close set regular longitudinal striæ from the apex across the volutions; pillar cavity very large; diameter a quarter of an inch.

Pulteney's Dorset. tab. 20, fig. 15, 16.

Test. Brit. tab. 24, fig. 3.

A common British shell, found under stones, old timber, and among moss.

Umbilicata, 13. *Umbilicata.* Shell horn-coloured, with five whorls; much rounded, deeply divided by the separating line, and finely striated across the whorls; apex a little produced; lip attenuated; pillar cavity large and deep; diameter one tenth of an inch.

Test. Brit. tab. 13, fig. 2.

Found by Mr Montagu at several places in England; we have likewise observed it common in Scotland. It is found in the same places with the preceding, to which it bears a resemblance, and with which it may easily be confounded.

14. *Lapicida.* Shell sub-pellucid, compressed, brown variegated with darker shades; whorls five, almost flat, the lowest whorl carinated or brought to a sharp edge; striated transversely; pillar cavity wide and deep; mouth suboval; margin sharp, white, outer lip reflected, inner lip spreading on the body; diameter three quarters of an inch. Lapicida,

Brit. Zool. tab. 83, fig. 121.

Brit. Shells. tab. 39, fig. 2.

Inhabits England in shady woods, as well as rocky exposed situations.

15. *Ericetorum.* Shell sub-pellucid; whorls six; the first remarkably rounded, the superior ones scarcely elevated above the body whorl; wrinkled transversely; on the upper part of the large whorl is a brown band, which continues spirally at the bottom of each of the smaller volutions, and marks their division; pillar cavity large and deep; mouth suborbicular; margin thin; diameter three quarters of an inch. Ericetorum,

Brit. Shells. tab. 151, fig. 2.

Brit. Zool. tab. 85, fig. 122. *H. albella.*

Common in England upon dry sandy heaths; has likewise been found in Iona, by Mr Hanson.

16. *Subcarinata.* Shell white, sub-pellucid with three whorls, the lower one large, the others small, a little produced and placed somewhat laterally; round the base of the body wreath are two fine ridges; pillar cavity deep and large; mouth oval, outer lip projecting considerably; inner lip reflected; diameter one tenth of an inch. Subcarinata,

Test. Brit. tab. 7, fig. 9.

Found by Mr Montagu in sand from Salcomb bay, and other places on the south coast of Devon.

17. *Depressa.* Shell light brown subpellucid; volutions three or four, the superior ones scarcely elevated above the body, lower volution cylindrical; pillar cavity large; mouth round, nearly even, lateral and not clasping the body, but spreading a little on that part. Depressa,

Test. Brit. tab. 13, fig. 5.

Found by Mr Montagu in sand from Whitsand bay, and Falmouth in Cornwall, and at Burrow island Devonshire.

18. *Paludosa.* Shell smooth, white, with four rounded volutions, well defined, apex little elevated; pillar cavity large; mouth round; margin thick, opake, white, reflected; diameter one tenth of an inch. Paludosa,

Lin. Trans. vol. viii. tab. 5, fig. 5.

Test. Brit. tab. 13. fig. 3. *var. H. crenella.*

Found among moss, under decayed leaves, and in marshes, common in England and Scotland. A variety sometimes occurs with the volutions striated across in a strong and regular manner, with a light brown epidermis. This was figured by Lightfoot, *Phil. Trans.* 76. tab. 3, fig. 1, 2, 3, 4.

19. *Unispiralis.* Shell white, opake, glossy; mouth round, with one whorl, with a central cavity on both sides. Unispiralis,

Test. Min. Rar. tab. 1, fig. 27.

Found at Sandwich; not common.

20. *Resupinata.* Shell horn-coloured, semi-pellucid, Resupinata,

Univalves.

glossy; mouth oval, large; spires of the tip turned backwards.

Test. Min. Rar. tab. 1, fig. 24.

From Sandwich; very rare.

Reticulata,

21. *Reticulata.* Shell white, pellucid; with one reticulated whorl; mouth round; central cavity small.

Test. Min. Rar. tab. 1. fig. 26.

From Reculver; extremely rare.

Tubulata,

22. *Tubulata.* Shell with three longitudinally striate whorls; a margined tube at the base, instead of a pillar cavity, extending beyond the surface of the shell.

Lin. Trans. vol. iii. tab. 13, fig. 35, 36.

Found on the coast of Pembrokeshire, by Mr Adam.

Fasciata,

23. *Fasciata.* Shell pellucid, white, the first spire marked with three transverse purple belts, the middle one broad, the lateral ones narrow; whorls three, smooth, the first large; mouth expanded, with a small pillar cavity.

Lin. Trans. vol. v. tab. 1, fig. 20, 21.

Nitidissima,

24. *Nitidissima.* Shell corneus, pellucid, with two whorls very finely striated transversely, extremity glossy; pillar cavity distinct.

Lin. Trans. vol. v. tab. 1, fig. 22—24.

Found with the preceding species.

Bicolor,

25. *Bicolor.* Shell smooth dull, inside of the shell white, pillar cavity small.

Lin. Trans. vol. v. tab. 1, fig. 25—27.

The four preceding species were found by Mr Adam on the coast of Pembrokeshire.

Margarita,

26. *Margarita.* Shell with four strong convex volutions; colour white, pearlaceous, with one faint rufous brown band on the upper part of the body whorl; mouth sublunated; inside nacred; base very convex; pillar cavity large; diameter one eighth of an inch.

Mem. Wer. Soc. vol. i. tab. 8, fig. 5.

First observed on the Scottish coast at Dunbar by Mr Laskey; we have found it on other parts of the same coast, and in Orkney and Zetland where it is plentiful.

Serpuloides,

27. *Serpuloides.* Shell white, glossy, with three cylindrical volutions destitute of striæ, apex depressed scarcely elevated above the other whorls; mouth orbicular, slightly adhering to the body, and turning considerably downwards, forming a large and deep pillar cavity.

Test. Brit. tab. 21, fig. 3.

Found on the coast of Devon by Mr Montagu. A variety very minutely striated occurs in great abundance on the coast of Zetland.

B. Base Imperforated.

Aspersa,

28. *Aspersa.* Shell marked with *fasciæ* of dark brown, sub-globose, with four volutions, the superior ones placed somewhat laterally; mouth semilunar, elongated, margin reflected, white; diameter about an inch and half.

Brit. Zool. tab. 84, fig. 129. *H. hortensis.*

Brit. Shells, tab. 131.

This is a very common species, about old garden walls, hedges and groves.

Nemoralis,

29 *Nemoralis.* Shell sub-globose, with five volutions, most frequently yellowish or reddish, fasciated with dark coloured bands, those with five bands have the two uppermost much smaller than the rest; mouth lunated margined; inner edge of the lip and pillar invariably of a dark colour; diameter scarcely an inch.

Brit. Shells, tab. 13.

A common British shell, in woods, hedges, and shady places.

Hortensis,

30. *Hortensis.* Shell sub-globose with five volutions, resembling the last, but in this the margin of the mouth is black; greatest diameter three quarters of an inch.

Found in similar situations with the preceding, in England and Scotland.

Arbustorum,

31. *Arbustorum.* Shell sub-globose with five volutions, a little rounded, well defined by the separating line, and wrinkled longitudinally with a single band of brown about the middle of the whorl; mouth lunated; margin reflected; the inside bordered with white; diameter about three quarters of an inch.

Brit. Zool. tab. 85, fig. 130.

Brit. Shells, tab. 136.

Delights in black boggy soil among trees; a common species in Britain. It is found likewise in Orkney and Zetland.

Fusca,

32. *Fusca.* Shell thin, pellucid, with five or six smooth whorls; mouth lunated; lip thin, not reflected, except a little at the lower angle, at which part is a small depression, but no pillar cavity; diameter about three eighths of an inch.

Test. Brit. tab. 13, fig. 1.

Found by Mr Montagu in a wood in Devonshire, and by Mr Laskey near Musselburgh, Haddingtonshire.

Lævigata,

33. *Lævigata.* Shell thin, fragile, flesh-coloured with three volutions; the first extremely large, the others very small, scarcely produced and placed laterally; wrinkled transversely, striated longitudinally; epidermis brown, rising into membranaceous ridges; mouth sub-orbicular, large, margin thin; diameter about three quarters of an inch.

Brit. Zool. tab. 86. fig. 139.

Brit. Shells, tab. 105.

Found sparingly upon the English shores; more plentifully on the Scottish coast, and in Orkney and Zetland.

Glutinosa,

34. *Glutinosa.* Shell thin, diaphanous, sub-orbicular; whorls three, the body whorl occupying almost the whole of the shell; mouth oval, large, extending nearly to the apex; length rather more than half an inch, breadth three eighths.

Test. Brit. tab. 16. fig. 5.

Found by Mr Boys in marshes at Deal, and by Mr Montagu in a water course near Reading in Berkshire.

Striata,

35. *Striata.* Shell, greenish white, pellucid; mouth oval, with three spires reflected on the back.

Test. Min. Rar. tab. 1. fig. 29.

From Sandwich; very rare.

Variegata.

36. *Variegata.* Shell sub-pellucid, smooth, with red lines; whorls four, the first ventricose; margin of the aperture very much spread.

Adam's on *Lin. Trans.* vol. iii. page 67.

Found by Mr Adam on the coast of Pembrokeshire.

Genus XVII. Nerita.

XVII. Nerita.

Shell subglobose, depressed beneath; mouth semicircular; pillar nearly transverse and flat.

Obs. In this genus the pillar is obliquely truncated, so that the opening is, in general lunated. Latreille and Lamarck have separated the genus Natica from that of Nerita. The Naticæ are distinguished by having a pillar cavity, and in being destitute of teeth. Those species are retained in the genus Nerita, which have an imperforated base, with the pillar sometimes furnished with teeth. As there are so few true Neritæ British, we will, for the present, retain the Naticæ along with them, and merely subdivide the genus.

A. Base imperforated. Nerita.

Littoralis,

1. *Littoralis.* Shell thick, strong, variously colour-

Univalves. ed; whorls five, the first large, the others small and placed laterally; mouth sub-orbicular; margin thickened within, the edge sharp; length three quarters of an inch.

Brit. Zool. tab. 87. fig. 143.
Brit. Shells, tab. 20. fig. 2.

Extremely common on all the British shores, creeping on stones a little below high water mark.

Fluviatilis, 2. *Fluviatilis.* Shells sub-pellucid, sub-oval, elegantly spotted; whorls three, the first very large, the others small, but well defined and placed laterally; apex minutely small; mouth lunated; outer lip thin; pillar lip broad, flat, and white; length three-eighths of an inch.

Brit. Shells, tab. 16. fig. 2.

Found in England in slow running rivers adhering to stones.

B. Base perforated. NATICA.

Glaucina, 3. *Glaucina.* Shell strong, smooth, glossy, variously coloured; whorls six, the first ventricose; apex pointed; mouth suboval, outer lip thin, even; pillar lip thick, reflected, forming a large and deep pillar cavity; length an inch and a half.

Brit. Zool. tab. 87. fig. 141.
Brit. Shells, tab. 20. fig. 1.

On the British shores, common, from Devonshire to Zetland.

Canrena, 4. *Canrena.* Shell resembling the last, but in this the pillar cavity is furnished with two spiral ridges and two grooves; diameter about half an inch.

British Shells, tab. 167. *N. intricata.*

First noticed as British by Mr Donovan, whose specimens are from Weymouth.

Nitida, 5. *Nitida.* Shell ovate, white, smooth, shining; spire short; mouth oval, gibbous beneath; the pillar cavity half closed; diameter scarcely half an inch.

Brit. Shells, tab. 144.

First ascertained to be British by Mr M'Leay, who found small specimens on the coast of Caithness, and we have observed it at St Andrew's, Fifeshire, and in Zetland.

Pallidula, 6. *Pallidula.* Shell sub-pellucid, light brown, with three whorls, the first very large; epidermis rough, brown; mouth semilunated, outer lip thin, fringed by the epidermis; pillar lip thick, white, concave, and perforated; inside glossy; length scarcely half an inch.

Brit. Shells, tab. 16. fig. 1.

In England rather rare. Common on the Scottish coast, in Orkney and Zetland.

Tuberosissima, 7. *Tuberosissima.* Shell pellucid, white, with four whorls; on the body whorl are four elevations broken into tubercles; pillar cavity large; diameter one eighth of an inch.

Test. Brit. tab. 29. fig. 5.

Found by Mr Laskey in the Frith of Forth.

Rufa, 8. *Rufa.* Shell smooth, glossy, of a livid purplish colour, with a white band round the top of the volutions, and two others on the body whorl; diameter more than half an inch.

Test. Brit. tab. 30. fig. 3.

Found near Dunbar, Haddingtonshire, by Mr Laskey.

Pellucida, 9. *Pellucida.* Shell smooth, pellucid, with three volutions.

Lin. Trans. vol. iii. page 67.

Found by Mr Adams on the Pembrokeshire coast.

Alba, 10. *Alba.* Shell smooth, sub-pellucid, with two volutions.

Lin. Trans. vol. iii. page 67. Univalves.

Found by Mr Adams along with the preceding species. These two species are probably the fry of N. glaucina.

GENUS XVIII. TROCHUS.

XVIII. Trochus. *Shell more or less conical; aperture somewhat angular, transversely contracted, with an oblique axis.*

Obs. Lamarck has separated from this genus those shells which have the pillar cavity crenulated or denticulated at the margin of the windings, and those which have a round opening with the two margins disunited, and a pillar truncated at the base forming a tooth projecting into the opening. The former he terms *Solarium,* the latter *Monodonta.*

A. Base perforated.

1. *Magus.* Shell with five or six tumid, sub-depressed whorls, well divided by the separating line, and wrought with fine spiral ridges; mouth compressed, angulated; pillar cavity large, deep, and grooved; diameter about an inch. Magus,

Brit. Zool. tab. 80. fig. 107.
Brit. Shells, tab. 8. fig. 1.

Not uncommon on the British shores from Devonshire to Zetland.

2. *Cinerarius.* Shell irregularly conical, spirally striated, with four or five volutions not much raised; colour cinererius marked with undulated lines of brown; mouth angulated; pillar cavity small but deep; inner lip a little reflected; diameter about five-eighths of an inch. Cinarerius,

Brit. Shells, tab. 74. the upper and two lower figures.

On the British coast common.

3. *Umbilicatus.* Shell strong, flattish, rounded at the top, not pointed; whorls five, nearly even, with obsolete striæ waved with lines of a light or dark purple; mouth compressed, angulated; pillar cavity large, deep; diameter three quarters of an inch. Umbilicatus,

Brit. Zool. tab. 80. fig. 106.

Found in similar situations with the last, and equally abundant.

4. *Tumidus.* Shell strong, subconic, tumid, with four whorls, wrought with fine close set spiral striæ, interrupted only by a deep separating line; body whorl flattened and subcarinated; pillar cavity small, and in old specimens frequently closed; mouth sub-quadrangular; diameter about a quarter of an inch. Tumidus.

Test. Brit. tab. 10. fig. 4.

On the English shores rare. Plentiful in Orkney and Zetland.

5. *Terrestris.* Shell thin, conic, with six flat longitudinally striated whorls, with a prominent ridge at the base of each; mouth compressed angulated; base flat, perforated, striated from the centre. Terrestris,

Brit. Zool. tab. 80. fig. 108.
Brit. Shells, tab. 111.

Found by Hudson on the mountains of Cumberland, and by Mr Morton in Northamptonshire.

6. *Fuscus.* Shell five spired, marginated, aperture roundish, with a pillar cavity. Fuscus,

Test. Min. Rar. tab. 2. fig. 58.

From Sandwich, common; Mr Walker.

B. Base imperforated.

7. *Crassus.* Shell subconic, with five rounded volutions, closely set with zigzag lines; mouth rounded Crassus,

Univalves. on the outer lip, angulated at bottom, with a toothlike protuberance; pillar lip smooth, white; diameter about an inch.

Brit. Shells, tab. 71. *T. lineatus.*

Frequent on the English coast. Mr Laskey found it at Dunbar.

Tenuis, 8. *Tenuis.* Shell thin, fragile, conical, with fine granulated ridges on each whorl; pillar reflects a little; diameter an inch and a quarter.

Brit. Shells, tab. 127. *T. papillosus.*

First described by Da Costa, who received it from Cornwall. Dr Pulteney has found it at Poole and Weymouth.

Ziziphinus, 9. *Ziziphinus.* Shell conic, pointed, with seven or eight whorls, wrought with several spiral ridges; aperture compressed angulated; inside nacred; base flattish.

Brit. Zool. tab. 80. fig. 103.

Common on the British shores and in Orkney and Zetland.

Exiguus, 10. *Exiguus.* Shell conic, with six volutions, pointed; each whorl wrought with four or five small, spiral crenated ridges, with a larger one at the base; aperture angulated; inside white; length three eighths of an inch; breadth a quarter of an inch.

Brit. Shells, tab. 8. fig. 2. *T. conulus.*

Not uncommon on the English coast.

Striatus. 11. *Striatus.* Shell conic, pointed, with six flat volutions, scarcely defined by any separating line, each wrought with eight or nine spiral ridges, intersected by very small longitudinal striæ.

Brit. Shells, tab. 155, fig. 1. *T. conicus.*

Found on the English coast, not frequent.

The claims of *T. cinereus* to admission among British shells are too feeble to warrant its insertion in the present list.

Family III. CONVOLUTED.

The shells of this family have a lengthened mouth, parallel with the length of the shell. The whorls, which are small segments of large circles, are wrapt round the pillar, and do not rise one above another, but embrace or inclose one another. Three genera are included, *Cyprea*, *Voluta*, and *Bulla*.

Genus XIX. Cypræa.

XIX. Cypræa. *Shell ovate, convex; margin involuted; spire small, and nearly covered over; mouth linear, extending the whole length of the shell, and toothed on both sides.*

Europæa, 1. *Europæa.* Shell oval, glossy, tumid, surrounded transversely with elevated striæ, which terminate within the lips, giving them a crenated appearance; colour pale purple, with generally three dark spots on the back; lips white.

Brit. Zool. tab. 70, fig. 82. *C. pediculus.*

Brit. Shells, tab. 43.

This species, which is common on our coast, is subject to great variations in different stages of its growth. In its youngest state, it is pellucid white, with three very small volutions; mouth suboval, outer lip attenuated, inner lip plain. This is the *Bulla diaphana* of *Test. Brit.* and *Voluta Ionensis* of *Brit. Zool.* In another stage of its growth, the back is still smooth, the edges of the lips crenated, and the apex a little produced. This has been termed *C. bullata.* Those species in which the dorsal striæ are distinct, but in which the spots are wanting, have been called *C. arctica.*

Voluta. 2. *Voluta.* Shell conoid, of a pale greenish colour, smooth, glossy, with the outer lip white; extreme volutions two, very small; mouth linear, terminated by a groove; both lips denticulated, the inner one faintly; pillar subplicated; length about half an inch.

Test. Brit. tab. 6, fig. 77.

Found by Mr Montagu in Salcomb Bay, and by Mr Laskey near Dunbar.

Genus XX. Voluta.

Shell ecaudated; mouth extending nearly the whole length of the shell; pillar twisted or plaited, without an interior lip or perforation. XX. Voluta.

1. *Tornatilis.* Shell with eight spires, the first large, the others small, pointed, of a pale purplish red, striated spirally, with two white bands on the body whorl; mouth long and narrow; pillar with one fold; length three quarters of an inch. Tornatilis,

Brit. Zool. tab. 71, fig. 86.

On the English and Scottish coasts not uncommon.

2. *Pallida.* Shell smooth, glossy, white, cylindrical; upper volution small; apex obtuse; mouth narrow, spreading a little at the base; pillar with four folds; length half an inch; breadth a quarter. Pallida,

Brit. Shells, tab. 66.

First noticed by Da Costa, who received it from the western coast.

3. *Denticulata.* Shell with seven or eight volutions, pointed, the lower one large; mouth oblong, oval, half the length of the shell; outer lip furnished with two or three tubercles near the margin; pillar plaited with three or four folds; length half an inch; breadth a quarter. Denticulata,

Test. Brit. tab. 20, fig. 5.

Found by Mr Montagu in Devonshire, at Weymouth by Mr Bryer, and at Dunbar by Mr Laskey.

4. *Alba.* Shell oval, white, with four finely striated volutions; mouth long and narrow, with four plications on the pillar; length one-tenth of an inch. Alba,

Test. Min. Ra. tab. 3, fig. 61.

From Sandwich and Sheppy island, Mr Walker; and Dunbar, Mr Laskey.

5. *Catenata.* Shell oblong, strong, pellucid, white, glossy, with four bands of opaque, white, oblong spots; upper volution scarcely defined; mouth the whole length of the shell, linear; outer lip thick; pillar quadruplicated; length a quarter of an inch; breadth at the top one-eighth. Catenata,

Test. Brit. tab. 6, fig. 2.

Found by Mr Swainson in St Austle Bay, near Fowey, Cornwall; and by Mr Laskey at Dunbar.

6. *Triplicata.* Shell ovate, smooth, chesnut brown, with six spires, the first very large; mouth contracted; pillar triplicated; spires very flat; length scarcely half an inch. Triplicata,

Brit. Shells, tab. 137.

Inserted as British, on the authority of a manuscript note of Da Costa's.

7. *Bidentata.* Shell strong, thick, pure white, with six or seven moderately smooth and somewhat glossy volutions, wrought with a few distant longitudinal wrinkles; mouth narrow, contracted at the upper angle; pillar much thickened, and folding back forms a cavity, and is furnished with teeth-like plications; length a quarter of an inch. Bidentata,

Test. Brit. tab. 29, fig. 3.

Found by Mr Laskey at Dunbar, Haddingtonshire.

8. *Hyalina.* Shell pellucid, white, tapering to an obtuse point; mouth contracted, base truncated and Hyalina,

Univalves.

canaliculated; outer lip smooth; pillar plain, with seven or eight thread-like striæ; length a quarter of an inch.

Test. Brit. tab. 29. fig. 5.

Found by Mr Laskey near Dunbar.

Heteroclita.

9. *Heteroclita.* Shell glossy, white, veined like ivory in a longitudinal direction, and furnished with eight or nine reversed whorls obtusely pointed; pillar with one plication; length a quarter of an inch; breadth one-third of its length.

Mem. Wer. Soc. vol. i. tab. 8, fig. 12.

Found by Mr Laskey near Dunbar.

We consider the *V. bullaoides* as scarcely entitled to a place among British shells.

XXI. Bulla.

Genus XXI. Bulla.

Shell convoluted; spires usually concealed; mouth longitudinal, somewhat contracted; the base entire; pillar smooth; lip acute.

A. Dextral.

Lignaria,

1. *Lignaria.* Shell oval, thin, brittle, yellowish brown, with numerous spiral striæ; mouth extending the whole length of the shell, contracted a little at the upper part; apex depressed; pillar visible to the end; length sometimes nearly two inches.

Brit. Zool. tab. 70, fig. 83.

Brit. Shells, tab. 27.

Found at Weymouth, Dorset, and in Cornwall and Devonshire; rare. It is common in Scotland, at St Andrew's, in the Frith of Forth, and has likewise been observed in Orkney.

Ampulla,

2. *Ampulla.* Shell oblong, smooth, glossy, mottled with light chesnut; no external volution, but the apex is sunk into a considerable cavity; mouth moderately wide; on the lower end of the pillar lip the shell is thickened, and of an opake white colour; pillar not visible to the end; length three-eighths of an inch.

Test. Brit. tab. 7, fig. 1.

Found by Mr Montagu in sand from Falmouth harbour; but rare.

Patula,

3. *Patula.* Shell smooth, glossy, white, oblong, the upper end extending beyond the body; base more extended; mouth large, terminating in a short canal at each end; pillar twisted, forming a furrow on its lip; outer lip plain and very thin; length one inch; breadth half an inch.

Brit. Zool. tab. 70, fig. 85, A.

Brit. Shells, tab. 143.

Found at Weymouth, according to Mr Pennant and Dr Pulteney. Mr Laskey has likewise found it on Portobello sands, near Edinburgh.

Aperta,

4. *Aperta.* Shell sub-orbicular, thin, pellucid, white, without any external convolution or pillar cavity, inner ip very small, slightly involuted, visible to the end; he mouth occupies nearly the whole of the shell. Length about half an inch.

Brit. Shells, tab. 120. fig. 1.

Test. Brit. vig. 2. fig. 1.

First noticed as British by Da Costa. Found in several places on the English shores; and at Dunbar by Mr Laskey.

Plumula,

5. *Plumula.* Shell ovate, oblong, depressed, pellucid; the convolution makes one turn; it is strongly wrinkled, and possesses two or three ray-like indentations running from the margin towards the apex; mouth extends the whole length of the shell; length half an inch.

Test. Brit. tab. 15. fig. 9.

Found by Mr Montagu at Milton sands, South Devon.

Catena,

6. *Catena.* Shell pellucid, white, glossy, transversely striated; apex obtuse without any visible whorl; mouth very large, occupying almost the whole of the shell except a small part at the top; diameter rarely exceeding one-tenth of an inch.

Test. Brit. tab. 7. fig. 7.

Found by Mr Montagu among sand in Bigberry bay Devon; at Tenby South Wales by Mr Adams, and at Dunbar by Mr Laskey.

Emarginata,

7. *Emarginata.* Shell pellucid, smooth; lip subarcuated.

Lin. Trans. vol. v. tab. 1. fig. 9—11.

Found by Mr Adams near Pembroke.

Denticulata,

8. *Denticulata.* Shell white, pellucid, oblong, nearly equal, obtuse, smooth, the mouth at top ending in a very acute tooth.

Lin. Trans. vol. v. tab. 1. fig. 3, 4, 5.

Found near Pembroke by Mr Adams.

Hydatis,

9. *Hydatis.* Shell oval, sub-pellucid, thin; epidermis ferruginous; body tumid, minutely striated transversely; no external volution, apex with a cavity; mouth large at the base, contracting a little at the top and extending rather beyond it; outer lip very thin, pillar lip a little thickened and whitish; pillar not visible to the end: length one inch.

Brit. Shells, tab. 88.

Not uncommon on the western coast of England; it has likewise been observed at Dunbar by Mr Laskey.

Akera,

10. *Akera.* Shell thin, elastic, horn-coloured, oval, somewhat wrinkled longitudinally; apex obtusely canaliculated; mouth large at the base, much contracted at the top; outer lip very thin; pillar lip a little thickened, white; inside white; pillar visible to the end; length about three quarters of an inch; breadth nearly half an inch.

Brit. Shells. tab. 79. *B. resiliens.*

First observed as British by the Rev. Mr Cordiner at Banff; has since been found on several parts of the British coast.

Cylindracea,

11. *Cylindracea.* Shell slender, cylindrical, smooth, glossy, white; aperture the whole length of the shell, narrow and dilated a little at the base; apex depressed, with a cavity; outer lip thin, acute, straight; inner lip thickened, opake, white; pillar a little indented. Length five-eighths of an inch.

Test. Brit. tab. 7. fig. 2.

Brit. Shells. tab. 120. fig. 2. 2.

Not uncommon on the English and Scottish shores.

Umbilicata,

12. *Umbilicata.* Shell oblong, oval, smooth, white; apex rounded with a cavity; mouth narrow, the whole length of the shell, dilating a little at the base; length one-eighth of an inch; breadth one half of its length.

Test. Brit. tab. 7. fig. 4.

Discovered by Mr Montagu amongst sand from Falmouth harbour sparingly.

Truncata,

13. *Truncata.* Shell subcylindric, opake, white, the upper part longitudinally striated, the lower plain; apex truncated with a cavity shewing the involutions; mouth the whole length of the shell, narrow, dilated a little at the base, and contracted in the middle. Size of the last.

Test. Brit. tab. 7. fig. 5.

Common to the shores of Cornwall and Zetland.

Obtusa,

14. *Obtusa.* Shell moderately strong, sub-cylindric, opake, wrinkled longitudinally; apex convoluted, obtuse; whorls four or five, very little produced; mouth

Univalves.

nearly the whole length of the shell, dilated at the base; inner lip thickened, smooth, white; length two-tenths.

Test. Brit. tab. 7. fig. 3.

On the English coast frequent. Very common in the Forth about Bo-ness.

Flexilis,

15. *Flexilis.* Shell pellucid, horn-coloured; apex white and opake, with a one-turned spire. Length half an inch.

Mem. Wer. Soc. vol. 1. tab. 8. fig. 6.

Found by Mr Laskey at Dunbar. Probably belongs to the genus Sigaretus.

B. Sinistral.

Fontinalis,

16. *Fontinalis.* Shell glossy, pellucid, horn-coloured, the body whorl large, the others very small; apex blunt; mouth oblong; length half an inch, breadth a quarter.

Lin. Trans. vol. 8. tab. 4. fig. 1.

In stagnant pools in England and Scotland common.

Rivalis,

17. *Rivalis.* Shell ovate, pellucid, with five spires, with an acute apex; mouth ovate oblong; length half an inch.

Lin. Trans. vol. viii. tab. 4. fig. 2.

First discovered by Mr James Hay in Hampshire. It has been found by Dr Leach in Duddingstone Loch near Edinburgh.

Hypnorum.

18. *Hypnorum.* Shell with five or six taper, smooth, glossy spires; the body whorl half the length of the shell; mouth narrow at the top, spreading a little at the base; outer lip extremely thin; pillar lip a little thickened; length five-eighths of an inch.

Lin. Trans. vol. viii. tab. 4. fig. 3.

Found in ponds and ditches in England.

DIVISION II. MULTILOCULAR.

The shells included in this Division are more complicated in their structure than those of the preceding species. They possess a cavity divided into compartments with a pipe of communication. All the British species are minute, and require the aid of the microscope for their examination. Although the species which are found in a recent state on our shores are very small, many species of a large size occur in the mineral strata, and indicate that the testacea of a former period of the earth's existence differed materially from the species which now exist. To this division of shells only four genera belong, the Nautilus, Orthoceres, Spirolina, and Miliola.

Genus XXII. Nautilus.

XXII. Nautilus.

Shell spiral, discoid; cavity divided into compartments by means of transverse septa or partitions, concave outward, and perforated by a tube.

Obs. This genus will, for the present, include several species belonging to other genera in the system of Lamarck. In a general system, the Gallican genera are unexceptionable, but in a limited description of species, its application would be attended with considerable inconvenience.

Beccarii,

1. *Beccarii.* Shell white, pellucid, with four or five volutions, with deep sulcated joints, ten in the first spire; above convex, beneath flat, and the markings less distinct; mouth turned upwards, not clasping the body whorl; syphon situated at the anterior side close to the second whorl.

Test. Min. Rar. tab. 3. fig. 63.

Test. Brit. tab. 18. fig. 4.

Frequent on the British shores, residing in *algæ* and shells.

Beccarii perversus,

2. *Beccarii perversus.* In every respect resembling the last, with the exception that the spires in this are reversed, or the shell is sinistral.

Test. Min. Rar. tab. 3. fig. 64.

More frequent than the preceding species.

Crispus,

3. *Crispus.* Shell with lateral whorls, furnished with about twenty flexuous crenated joints in the exterior whorl, marked by elevated striæ; outer edge carinated; inner whorl concealed; mouth clasping the body, semicordate, and furnished with a small perforation or syphon.

Test. Brit. tab. 18. fig. 5.

Test. Min. Rar. tab. 3. fig. 65.

Frequent on the English shores.

Lævigatulus,

4. *Lævigatulus.* Shell pale, ferruginous, opake, smooth, with about ten visible flexuous rays of a deeper colour which mark the septa; both sides convex declining to a marginal edge; mouth surrounded with a margin forming a triangle; syphon near the exterior angle.

Test. Min. Rar. tab. 3. fig. 67.

Test. Brit. tab. 18. fig. 7. 8.

Found by Mr Walker at Sandwich and Sea Salter, but not common.

Calcar,

5. *Calcar.* Shell smooth, with six joints on the body whorl, marked by as many flexuous elevated striæ radiating from the centre; back strongly carinated; both sides equally convex; interior volutions lost after entering the aperture, which is semicordate, clasping the body equally on both sides, and furnished with a small perforation.

Test. Brit. tab. 15. fig. 4.

Found by Mr Montagu on the English coast.

Lobatulus,

6. *Lobatulus.* Shell roundish or oblong; above convex, with six or seven lobes, beneath flat; the interior volution only marked by one or two small elevations, and frequently not visible; aperture minutely small; diameter about a line.

Test. Min. Rar. tab. 3. fig. 71.

Found in Kent and Devonshire. Sessile adhering to Algæ.

Concameratus,

7. *Concameratus.* Shell sub-orbicular, compressed, flat beneath, slightly convex above, with three irregular volutions and numerous dissimilar concamerations; the exterior whorl has about nine glossy tumid cells of unequal size; diameter half a line.

Test. Brit. sup. page 168.

Found by Mr Montagu in similar situations with the former.

Depressulus,

8. *Depressulus.* Shell semi-pellucid, glossy, white, depressed, with about nine visible septa, radiating from the centre in curved lines marked by their opacity; sides similar; the mouth is somewhat like N. calcar, but does not clasp the body so much.

Test. Min. Rar. tab. 3. fig. 68.

Test. Brit. tab. 18. fig. 9.

Found at Reculver, very rare, Mr Walker.

Umbilicatulus,

9. *Umbilicatulus.* Shell compressed, sub-pellucid, white, with nine or ten raised joints; the anterior end or mouth clasping the body; whorl nearly equal, within which any interior volution is lost.

Test. Brit. tab. 18. fig. 1.

Found at Sandwich by Mr Walker, and at Kingsbridge by Mr Montagu.

Crassulus,

10. *Crassulus.* Shell spiral, strong, opake, pale brown, with numerous close-set elevated joints; sides compressed, similar, with a central cavity, shewing part

Univalves.

of the interior volution; mouth oblique, scarcely clasping the body.

Test. Min. Rar. tab. 3. fig. 70.
Test. Brit. tab. 18. fig. 2.

On the English coast, rare.

Lacustris,

11. *Lacustris.* Shell compressed, subcarinated, spiral, smooth, glossy; horn-coloured; above convex; apex depressed with three visible volutions; these are bordered on their outer edge with an opake whitish line; under side flat with a deep cavity; chambers distant; mouth narrow, subcordate, clasping the body whorl; diameter nearly a quarter of an inch.

Phil. Trans. vol. xvi. tab. fig. 1—7.
Test. Min. Rar. tab. 1. fig. 28.
Test. Brit. tab. 6. fig. 3.

In marshes and ditches in England not uncommon.

Carinatulus,

12. *Carinatulus.* Shell oblong, carinated, with a narrow oval aperture; colour whitish, transparent like glass.

Test. Min. Rar. tab. 3. fig. 72.

From Seasalter and Sandwich, very rare; Mr Walker.

Inflatus,

13. *Inflatus.* Shell opake, brown, with three lobated whorls; in the first whorl are five extremely ventricose articulations; anterior end sub-globose; syphon placed as in N. beccarii.

Test. Brit. tab. 18. fig. 3.

Found amongst sand on the coast of Devon by Mr Montagu.

XXIII. ORTHOCERA.

Genus XXIII. Orthocera.

Shell straight, or slightly bent, rather conical, the chambers separated by transverse septa, which are pierced by a tube.

Recta,

1. *Recta.* Shell straight, or a little arcuated, with smooth joints; smaller at the posterior extremity than at the mouth.

Test. Min. Rar. tab. 3, fig. 74.
Test. Brit. tab. 19, fig. 4 and 7. Nautilus.

Found at Sandwich by Mr Boys; very rare.

Radicula,

2. *Radicula.* Shell sub-conic, elongated, with eight or nine sub-globose articulations; smooth, opake, brown; aperture a small syphon.

Test. Brit. tab. 6. fig. 4, and tab. 14, Fig. 6. Nautilus.

This species varies much in shape. Found at Sandwich by Mr Boys.

Subarcuata,

3. *Subarcuata.* Shell sub-cylindric, sub-arcuated, with three conspicuous globose articulations at the larger end, the remaining joints being scarcely visible; mouth a small produced syphon; colour pellucid, glossy, white; length a tenth of an inch.

Test. Brit. tab. 6. fig. 5. Nautilus.

Found at Sandwich by Mr Boys.

Jugosa,

4. *Jugosa.* Shell sub-arcuated, sub-cylindric, a little tapering, with nine ridged globose articulations; mouth extended to a small conical syphon; the extreme joint at the smaller end longer than the others near it; length about the eighth of an inch.

Test. Brit. tab. 14, fig. 4. Nautilus.

Found by Mr Boys on the Kentish coast.

Costata,

5. *Costata.* Shell straight, sub-cylindric, a little tapering, with twelve raised articulations, furnished with four equidistant, strong longitudinal ribs running the whole length of the shell; mouth extended in a conical syphon; length a quarter of an inch.

Test. Brit. tab. 14, fig. 5. Nautilus.

Found on the Kentish coast by Mr Boys.

Legumen,

6. *Legumen.* Shell sub-arcuated, smooth, glossy, compressed, and nearly of equal size throughout; the ends are rounded, and a little contracted; the anterior end surrounded with an oblique margin above, which rises into an obtuse syphon; chambers eight or nine in number, with oblique septa; length an eighth of an inch.

Test. Min. Rar. tab. 3, fig. 74.
Test. Brit. tab. 19, fig. 6.

Found in sand on the coast of Kent and South Devon, by Mr Montagu.

Spinulosa,

7. *Spinulosa.* Shell with three extremely globose articulations of a pale chesnut colour, covered with spines; the superior bulb a little elongated, to form the syphon; the spires all incline to the posterior end; length one-tenth of an inch.

Test. Brit. tab. 19, fig. 5. Nautilus.

Found by Mr Boys.

Bicarinata,

8. *Bicarinata.* Shell sub-cylindric, arcuated, with eleven sub-globose bi-carinated articulations; the joints gradually decrease a little to the posterior end, which is rounded; length one eighth of an inch.

Test. Brit. Sup. page 86. Nautilus.

Found by Mr Boys at Sandwich. It resembles in shape the O. subarcuata.

Linearis.

9. *Linearis.* Shell straight, linear, a little compressed, and nearly of equal size throughout; furnished with faint ribs at the lesser end, which take an oblique direction, and scarcely extend half the length of the shell; chambers about fourteen in number; anterior end smooth, with a produced syphon, posterior end rounded; length a quarter of an inch.

Test. Brit. tab. 30, fig. 9. Nautilus.

Discovered by Mr Montagu amongst a parcel of minute shells sent to him from Dunbar by Mr Laskey.

XXIV. SPIROLINA.

Genus XXIV. Spirolina.

Shell in part spirally convoluted; the turns contiguous; the last whorl produced, and straight at the end; chambers divided by transverse perforated septa.

Semilitua,

1. *Semilitua.* Shell elongated, sub-arcuated, with elevated joints; apex incurvated; mouth with a small produced syphon; colour opake, brown.

Test. Brit. tab. 19, fig. 3. Nautilus.

On the English coast.

Subarcuatula.

2. *Subarcuatula.* Shell sub-arcuated; anterior part of the shell with about four chambers, posterior half convoluted; back carinated, and slightly indented at the division of the cells; front margin obtusely rounded; length one-eighth of an inch.

Test. Brit. tab. 19, fig. 1.
Test. Min. Rar. tab. 3, fig. 73. Nautilus.

From Shippy island, very rare, Mr Walker.

XXV. MILIOLA.

Genus XXV. Miliola.

Shell transverse, ovate-globose or elongated, with transverse chambers involving the axis, and in three directions; the opening small at the base of the last chamber.

Obs. The species which we have included in this genus, belong to the genus Vermiculum of Mr Montagu. He separated them from the genus Serpula of Linnæus, from the circumstance of their being independent, or not attached to other bodies. Their multilocular cavity point out their connection with the shells we have been just now treating of, so that we have willingly adopted the genus which Lamarck formed for their reception.

Bicornis,

1. *Bicornis.* Shell white, opake, with three chambers, the middle one small, the outer ones rounded and

Univalves. larger; suboval, compressed, and striated longitudinally on the longer side from the aperture; mouth small, orbicular; length one line.

Test Min. Rar. tab. 1, fig. 2.

Found by Mr Boys at Sandwich and Reculver.

Perforata, 2. *Perforata.* Shell semilunar, perforated; colour white, opake, glossy.

Test. Min. Rar. tab. 1, fig. 3.

Found at Sandwich and Cornwall. Probably a mutilated specimen of the preceding.

Intorta, 3. *Intorta.* Shell oval, compressed, opake, glossy, composed of three and sometimes four compartments, inner ones small; wrinkled transversely; aperture compressed semilunar; diameter one-tenth of an inch.

Test. Min. Rar. tab. 1, fig. 1.

On the British shores frequent.

Subrotunda, 4. *Subrotunda.* Shell sub-orbicular, sub-compressed, smooth, glossy, opake; chambers three, the middle one elevated above the others on the upper side, but not visible beneath; mouth small, angulated; margin in live shells yellow; diameter about half a line.

Test. Min. Rar. tab. 1, fig. 4.

Found among small sand, on the English shores common.

Oblonga. 5. *Oblonga.* Shell oblong, compressed, opake, glossy, white; on one side, the shell is divided into two parts by a single longitudinal suture; on the other side, the middle compartment is surrounded with a faint depression, that separates it from the exterior one, and is more elevated; mouth a little produced, oval, margin yellow; length not half a line.

Test. Brit. tab. 14, fig. 9.

In sand from Salcomb Bay, Devonshire.

ORDER II. BIVALVES.

Bivalves. This order of testaceous bodies was invented by Aristotle, and has been adopted by succeeding conchologists. It consists of an assemblage of shells which are composed of two concave plates, united laterally to each other by means of a hinge. The genera may be conveniently arranged in two divisions, depending on the form of the hinge. Other characters might be employed in the formation of subsidiary Sections and Families. For instance, the circumstance of the valves being closed or gaping; the shells equilateral or inequilateral, equivalved or inequivalved. The internal or external insertion of the cartilage of the hinge ought to be closely attended to in a general arrangement; but at present we choose to employ such characters as helps merely, in the distribution of species.

DIVISION I. DENTATED.

Dentated. This Division comprehends such shells as are furnished with teeth at the hinge. These teeth vary in number, form, and position, in the different species, and are employed as marks in the construction of the genera.

Genus XXVI. Mya.

XXVI. Mya. *Shell generally gaping at one end, and furnished with strong, broad, thick teeth at the hinge, not inserted into the opposite valve.*

A. Valves Gaping.

Glycymeris, 1. *Glycymeris.* Shell oblong, thick, transversely wrinkled, and gaping at both ends; hinge furnished with a thick primary tooth, and a smaller one, besides a series of wrinkles. Length five inches, breadth nine or ten.

Brit. Shells, tab. 142.

This species is scarcely admissible into a list of British shells. It was introduced by Mr Donovan, merely from the circumstance of its occurring in deep water between the Dogger-bank and the eastern coast of England, and likewise from its being acknowledged as British by some English collectors.

Pholadia, 2. *Pholadia.* Shell thin, opake, of an oval shape, marked with fine concentric striæ; beak small, prominent, and placed at one end; valves, when shut, have a large oval gape in front; hinge furnished with a small plate projecting inwards.

Brit. Zool. tab. 44. fig. 19.

First noticed from Weymouth by Pennant. Found on the Dorset coast by Dr Pulteney also, and on the Devonshire coast by Mr Montagu.

Arenaria, 3. *Arenaria.* Shell oval, moderately concave, rough, with concentric striæ; beaks prominent; hinge with one valve, furnished with a broad, thick, erect tooth, by which it is joined to the toothless valve; the smaller end gapes, and is reflected. Length two inches and an half, breadth nearly four inches.

Brit. Zool. tab. 42. fig. 16.

At the mouth of rivers on the English and Scottish shores, frequent.

Truncata, 4. *Truncata.* Shell truncated at the smaller end where it gapes, and concentrically wrinkled; valves concave and reflected at the smaller end; tooth broad and erect. Length two inches or more, breadth about three.

Brit. Zool. tab. 41. fig. 14.

This species is found lodged under gravel at low water mark, on various parts of the British shores. It is the shell which Pennant should have referred to as the one eaten by the Hebridians. In Orkney and Zetland it is used as a supper dish when boiled, and is called *Smurslin.*

B. Valves Closed.

Margaritifera, 5. *Margaritifera.* Shell ovate-oblong, sub-arcuated opposite the hinge, covered with a black epidermis, usually worn off at the beaks; a single tooth in one valve locks into a bifurcated tooth in the other. Length two inches and a half, breadth five inches.

Brit. Zool. tab. 43. fig. 18.

This shell is found in several rivers of Britain. It lives in those which are rapid, and which flow in mountainous countries. It often produces pearls of a considerable size, and of a good colour.

Ovalis, 6. *Ovalis.* Shell strong, oval, of a dusky green colour, almost black at the smaller end; beaks near the larger end; hinge furnished with one tooth, which locks into a bifurcated tooth in the opposite valve, these are strong and crenated; there are likewise two lateral laminæ in one valve, and one in another. Length two inches, breadth four inches.

Brit. Shells, tab. 101. M. depressa.

——— tab. 121. M. ovata.

Found in England in slow running rivers.

Bivalves.

Pictorum, 7. *Pictorum.* Shell sub-arcuated, olive green, concentrically wrinkled; beak near to one side; hinge nearly straight, from which it declines alike to both ends; a single broad crenated tooth, with two lateral laminæ in one valve, and one in the opposite, lock into each other. Length one inch, breadth an inch and three quarters.

Brit. Shells, tab. 174.

Found by Mr Montagu in the river Kennet, above the town of Newbury, in Berkshire.

Suborbicularis, 9. *Suborbicularis.* Shell sub-pellucid, sub-orbicular, faintly striated transversely; margin opposite the hinge nearly straight; hinge central, with a single tooth immediately under the beak, locking into a double one in the opposite valve, with a laminated tooth behind the beak in each, somewhat remote. Length three-eighths of an inch, breadth half an inch.

Test. Brit. tab. 26. fig. 6.

Discovered by Mr Montagu in limestone at Plymouth, and detached from any other substance in Salcomb Bay. Mr Laskey found it at Dunbar, and we have found it in the Murray Frith, and in Zetland.

Bidentata, 10. *Bidentata.* Shell sub-oval, thin, compressed, dirty white; beak small, placed near to one end, and a little reclined; hinge with two broad erect laminated teeth in one valve. Length one-eighth of an inch, rather more in breadth.

Test. Brit. tab. 26. fig. 5.

Found by Mr Montagu in Salcomb Bay, Devonshire, burrowed in old oyster shells.

Decussata, 11. *Decussata.* Shell ovate, white, with concentric ridges, decussated by regular longitudinal striæ, forming tubercles at the anterior end; margin waved; beak obtuse, recurved, and placed nearest to one end; hinge with a broad erect tooth in one valve, and a projecting indented lamina on the other for its reception. Length nearly half an inch, breadth rather more.

Test. Brit. tab. 28. fig. 1.

Found near Dunbar, where it is rare.

Purpurea, 12. *Purpurea.* Shell ovate, slightly wrinkled transversely, and of a purple colour about the beak, shaded to a white towards the margin; beak placed considerably to one side, and turning towards the shorter end; hinge with a single erect tooth in each valve, slightly bifid. Diameter about a line.

Found by Mr Montagu amongst coralline in deep water on the coast of Devon; very rare.

Ferruginosa, 13. *Ferruginosa.* Shell subovate, moderately convex, white, with obsolete wrinkles; beak obtuse, placed nearest to one end; front margin nearly straight; hinge furnished with two projecting teeth, one of which is erect, the other turns inwards, and slopes downwards; the teeth are separated by a large triangular notch. Length about a quarter of an inch, breadth half an inch.

Test. Brit. tab. 26. fig. 2.

Found by Mr Laskey on the shore near Dunbar. It is probably a native of Weymouth.

Nitens. 14. *Nitens.* Shell ovate, of a pink colour, shaded to white at the shorter end, and regularly striated concentrically; beak prominent, but scarcely central; hinge furnished with a single tooth in one valve, which shuts into a deep cleft between two slight elevations in the other. Diameter about three-eighths of an inch.

Mem Wernerian Soc. vol. i. tab. 8. fig. 4.

Found by Mr Laskey at Dunbar; extremely scarce.

XXVII. Ligula.

Genus XXVII. Ligula.

Shell equivalve; hinge with a broad erect tooth in each valve, projecting inwards, furnished with a pit or cavity for the reception of the connecting cartilage; in some species a minute erect tooth.

Obs. This genus was formed by Mr Montagu for the reception of a few species, which are included by some conchologists in the genera Mya and Mactra.

Prætenuis, 1. *Prætenuis.* Shell oval, thin, brittle, flat, marked with a few concentric striæ; beak small, pointed, turned to one side; valves a little gaping at the smaller end; hinge with a broad tooth in each valve, hollowed in the middle, projecting horizontally inwards; length above half an inch, breadth one inch.

Test. Brit. tab. 1, fig. 2.

Brit. Shells, tab. 176.

Found in several places on the English coast. Mr Laskey found it at Portobello sands, and we have seen it in Zetland.

Pubescens 2. *Pubescens.* Shell thin, brittle, oval, white, truncated at the smaller end; behind the cartilage slope, one valve turns up and embraces the other valve; beak nearly central; hinge, with one broad tooth projecting inwards; length two inches long, and three inches wide.

Brit. Shells, tab. 82.

Brit. Zool. tab. 47, fig. 26. Young.

Found on the Cornwall and Devonshire coast. The young shells are frequent on the Scottish coast as far north as Zetland.

Distorta, 3. *Distorta.* Shell subpellucid, thin, fragile, rugged, and distorted; valves convex; beak small, nearly central; hinge, with a broad subtriangular tooth; length an inch and three quarters, breadth two inches and a half.

Test. Brit. tab. 1, fig. 1.

Found on the coast of Cornwall and Devon by Mr Montagu. It sometimes burrows in limestone.

Compressa, 4. *Compressa.* Shell flat, thin, sub-oval, sub-triangular, concentrically wrinkled; beak small, central; hinge without lateral teeth; primary teeth small, a single one locking into a bifid tooth in the opposite valve; length an inch and a half, breadth two inches.

Pult. *Hutch. Dorset.* tab. 17, fig. 1. Mactra compressa.

Brit. Shells, tab. 64, fig. 1. Tellina plana.

Found in abundance at the mouths of rivers, but never beyond the flux of the tide.

Tenuis, 5. *Tenuis.* Shell equilateral, compressed, subtriangular, semipellucid, thin, concentrically wrinkled; beak small, central, much produced; hinge furnished with a bifurcated tooth in one valve, and a plain tooth in the other, with a remote lateral tooth in each valve; length a quarter of an inch, breadth little more.

Test. Brit. tab. 17, fig. 7.

Found by Mr Montagu at Southampton, by Mr Bryer at Weymouth, and by Mr Laskey at Musselburgh.

Boysii, 6. *Boysii.* Shell oval, flat, thin, pellucid, almost smooth; beak placed near the small end, and a little turned at the apex; hinge, with small primary teeth; cartilage cavity broad; lateral teeth in one valve only, broad, elevated; length half an inch, breadth three quarters.

Test. Brit. tab. 3, fig. 7.

First discovered at Sandwich by Mr Boys. Mr Montagu has likewise found it on the coast of Devon and Dorset. It is likewise common on the Portobello sands near Edinburgh.

Prismatica 7. *Prismatica.* Shell oblong, flat, thin, glossy, white, attenuated at one end, and obsoletely striated concen-

Bivalves. trically; beak small, and placed nearest to the smaller end, to which it turns; hinge furnished with a horizontal tooth, and a minute erect tooth; length three-eighths of an inch, breadth six-eighths.

Test. Brit. tab. 26, fig. 3.

Found by Mr Laskey on the shore at Dunbar. Mr Montagu has likewise found a single valve on the coast of Devon.

Substriata. 8. *Substriata.* Shell sub-ovate, white, sub-pellucid, wrought with distant, obsolete, elevated, longitudinal striæ; beak prominent; hinge furnished with a slight projection inwards, margined so as to form a cavity.

Taken by deep dredging among *Corallines,* on the coast of Devon, by Mr Montagu.

Genus XXVIII. Solen.

XXVIII. Solen. *Shell equivalved, transversely elongated, gaping on each side; the hinge teeth single in each valve, or double in one valve; beaks very small; the ligament external, and most frequently near to the extremity of the shell.*

Siliqua, 1. *Siliqua.* Shell straight, sub-cylindric, truncated at one end, rounded at the other; striated transversely and then longitudinally towards the back; a diagonal line from the hinge to the opposite end marks the turn of the longitudinal striæ; teeth in one valve single, with a remote lateral lamina; in the other valve two teeth, and a lateral inclined one; length an inch, breadth eight inches.

Brit. Zool. tab. 45, fig. 20.

Common on the sandy shores buried to the depth of a foot or more near low water mark. It is an article of food in many places.

Novacula, 2. *Novacula.* Shell resembling the last, except the hinge, in which it differs; the teeth are two in number, one on each valve, strong, blunt, and curved, and hook into each other when the shell is closed; no lateral laminæ; length one inch, breadth eight inches.

Test. Brit. page 47.

Found near Laugharne, Caermarthenshire, by Mr Montagu.

Ensis, 3. *Ensis.* Shell sub-cylindrical, arcuated; hinge, with a single tooth and a lateral lamina in one valve, which lock into two teeth and double laminæ in the opposite valve; length three quarters of an inch, breadth between five and six inches.

Brit. Zool. tab. 45, fig. 22.

Common in similar situations, as the S. siliqua.

Vagina, 4. *Vagina.* Shell cylindric, straight, rather truncated at both ends; the end next the hinge a little reflected; striated transversely, each stria running longitudinally across the shell, but not marked with a diagonal line; hinge close to one end, furnished with a single small compressed tooth in each valve, which lie by the side of each other when closed; length one inch, breadth five inches.

Brit. Zool. tab. 46, fig. 21.

Brit. Shells, tab. 110. S. marginatus.

This shell was first noticed by Pennant from Anglesea. Found at Weymouth by Dr Pulteney, and near Laugharne, Caermarthenshire, and at Kingsbridge, Devonshire, by Mr Montagu.

Pellucidus, 5. *Pellucidus.* Shell oblong, sub-arcuated, pellucid, fragile, compressed, and rounded at each end; hinge near to one end, furnished with a single small tooth in one valve, locking into two in the opposite, with a lateral process in each; length a quarter of an inch, breadth an inch and a quarter.

Brit. Zool. tab. 46, fig. 23.

First described by Pennant from Anglesea. Found in Cornwall, Kent, and Devon, by Mr Montagu. It is common on Portobello sands near Edinburgh. Bivalves.

6. *Legumen.* Shell straight, oblong, pellucid, thin, of a white colour; hinge near the middle, and furnished with two small teeth in one valve, receiving a single one from the opposite; length an inch, breadth four inches. Legumen,

Brit. Zool. tab. 46, fig. 24.

Brit. Shells, tab. 53.

On the English shores, but not common.

7. *Fragilis.* Shell thin, pellucid, fragile, glossy, white, somewhat depressed in the middle from the hinge to the opposite margin, oblong, rounded at both ends; hinge near the middle, furnished with a small subulate tooth in one valve, in the other two, one of which is subulate, the other broad. Fragilis,

Pult. *Dorset.* tab. 5, fig. 5.

Found on Studland beach by Dr Pulteney, at Weymouth by Mr Bryer, and at Dunbar by Mr Laskey.

8. *Antiquatus.* Shell thin, subpellucid, wrought with fine concentric striæ, ends rounded, and gaping; hinge placed near the centre, with a single tooth in one valve, locking in between two in the opposite; these are erect, and project beyond the margin; length one inch, breadth two inches. Antiquatus,

Brit. Shells, tab. 114.

Brit. Zool. tab. 46, fig. 25. S. cultellus.

Mr Pennant first gave this species as a British shell from Weymouth. It has occurred to us in Zetland.

9. *Minutus.* Shell opake, whitish, rugose or wrinkled transversely, sub-oval, truncated at one end near the hinge; valves dissimilar, each furnished with two rows of spines from the beak to the larger end; hinge teeth two in one valve, and one in another, with a small cavity, minute; length half an inch, breadth upwards of an inch. Minutus,

Test. Brit. tab. 1, fig. 4.

This species was observed by Cordiner in the Murray Frith. Mr Montagu has found it burrowed in limestone at Plymouth. In Scotland, it is common among the roots of fuci.

10. *Vespertinus.* Shell ovate, depressed, marked with concentric striæ; beak nearly central, small; teeth two in one valve, and one in another, erect, and likewise a strong projecting lamina in each; length an inch and quarter, breadth two inches and a half. Vespertinus,

Brit. Zool. tab. 47, fig. 27. Tellina depressa.

Brit. Shells, tab. 41, fig. 2.

First figured by Pennant. Found on the Dorset and Devon coasts. Mr Laskey found it at Dunbar.

11. *Squamosus.* Shell flat, pellucid, thin, white, of a sub-orbicular shape, minutely punctured; beak small, pointed, central; teeth two in each valve, double; length three-eighths of an inch, breadth half an inch. Squamosus.

Test. Brit. page 565.

This species has been found only by Mr Montagu in sand, from Salcomb bay, Devonshire.

Genus XXIX. Tellina.

Shell equivalved, orbicular or transverse, with an irregular fold on the anterior part; hinge with one or two teeth, and remote lateral teeth. XXIX. Tellina.

Obs. This genus in the Linnæan system, is in great confusion. The French conchologists, with much propriety, have removed the *Tellina cornea* of Lin. and its congeners into a new genus, which they denominate Cyclas. Mr Montagu has likewise separated these shells

Bivalves.

from the genus Tellina, and inserted them among the *Cardia*. The T. inequivalvis forms another new genus termed Pandora.

Ferroensis,

1. *Ferroensis.* Shell flat, oblong, oval, transversely striated; beak very small, nearly central; hinge furnished with two teeth in each valve; from the beak an oblique elevated ridge runs to one end; length three quarters of an inch, breadth an inch and a half.

Brit. Zool. tab. 47, fig. 31. T. incarnata.

Brit. Shells, tab. 60. T. trifasciata.

Common on the shores of Britain from Cornwall to Zetland.

Squalida,

2. *Squalida.* Shell thin, flat, sub-oval, faintly striated concentrically, the anterior end running into a beak; hinge with two teeth in one valve and three in the other, one of which is a little remote; the small end of one valve reflects a little outwards, and forms a depression on the surface, the other turns inwards to correspond; length an inch, breadth three quarters.

Pult. *Hutch. Dor.* tab. 5. fig. 2.

Brit Shells, tab. 63. T. Depressa.

First noticed as British by Dr Pulteney, who found it near Poole, and at Weymouth, Dorsetshire; Mr Montagu has found it in Cornwall and Devon; Mr Donovan in Pembroke; and Mr Laskey at Dunbar.

Læta,

3. *Læta.* Shell ovate, oblong, flat, and moderately strong, marked with regular concentric striæ; beak small, pointed, nearly central; hinge furnished with three teeth, the outer one on the anterior side bifid, the other exterior one broad; in each valve one remote lateral lamina; length three quarters of an inch, breadth an inch and three-eighths.

Brit. Shells, tab. 23. T. inæquistriata.

On the English shores rare. Found at Dunbar by Mr Laskey.

Donacina,

4. *Donacina.* Shell thin, sub-oval, compressed, semi-pellucid, faintly marked with yellowish concentric striæ, and radiated with red; beak small, and placed near to one end; the cartilage end short and sub-truncated; the hinge is furnished with two teeth in one valve, and a single tooth in the other; length about half an inch, breadth three quarters.

Lin. Trans. vol. viii. tab. 1. fig. 7.

Found on several parts of the English coast, and in Scotland at Dunbar.

Tenuis,

5. *Tenuis.* Shell thin, brittle, flat, sub-pellucid, suboval, with a few concentric wrinkles; beak small, placed nearly central; cartilage end somewhat pointed; variously coloured; length half an inch, breadth three quarters.

Brit. Zool. tab. 48, fig. 49. T. planata.

Brit. Shells, tab. 19, fig. 2.

Common on all the sandy shores of Britain.

Striata,

6. *Striata.* Shell sub-oval, flat, thin, sub-pellucid, of a rosy white colour, darkest towards the beaks, marked with fine concentric striæ; beaks small, pointed, not quite central; cartilage slope indented; primary teeth two, with strong remote laminated ones on each side; length one inch, breadth five-eighths of an inch.

Test. Brit. tab. 27, fig. 2.

Found by Mr Bryer on the beach between Weymouth and Portland.

Fabula,

7. *Fabula.* Shell thin, pellucid, compressed, oval, white; beaks nearly central, small, pointed, and turning a little to one side; anterior side slopes to an obtuse point; the opposite end is much larger and rounded; left valve finely striated in a diagonal direction; hinge with three teeth in one valve, and two in the other; length five-eighths of an inch, breadth an inch.

Brit. Shells, tab. 97.

Not uncommon on sandy shores.

Bivalves.

Similis,

8. *Similis.* Shell ovate, compressed, with both valves diagonally striated five sixths over the surface; beaks not curved; breadth about half an inch.

Brit. Miscel. page 29, tab. 75.

First described by Mr Sowerby. It inhabits the shores of Brighton, in company with T. fabula.

Solidula,

9. *Solidula.* Shell strong, convex sub-orbicular; colour various; beaks near the middle; hinge with two small teeth in each valve; length three quarters of an inch, breadth rather more.

Brit. Zool. tab. 49, fig. 32. T. carnaria.

A common littoral shell. It is often found at the mouths of large rivers, but not beyond the influence of the tide. Thus it occurs in the Tay as far up as Flisk.

Fausta,

10. *Fausta.* Shell sub-orbicular, somewhat compressed, white, with numerous fine concentric striæ; at the posterior end a fissure from the beak to the margin; beak central; hinge furnished with strong lateral teeth; one of the primary teeth in each valve bifid; diameter an inch and three quarters.

Lin. Trans. vol. viii. tab. 1, fig. 8.

Brit. Shells, tab. 98.

Found in Dorsetshire by Dr Pulteney, in Devonshire by Mr Montagu, and in Pembrokeshire by Mr Donovan.

Crassa,

11. *Crassa.* Shell strong, thick, sub-orbicular, with fine close set concentric striæ, interrupted by a few courser ridges; left valve convex, the other more compressed; beak placed a little to one side; hinge with two teeth in each valve, one of which is bifid; in the left valve two lateral teeth, one more remote than the other.

Brit. Zool. tab. 48, fig. 28.

Brit. Shells, tab. 103. T. rigida.

Found on the south coast of England; and at Aberlady bay by Mr Laskey.

Proficua,

12. *Proficua.* Shell sub-orbicular, sub-diaphanous, beset with numerous fine regular elevated ridges, the furrows crossed with minute striæ; beak small, prominent, nearly central; hinge, with two small central teeth, and broad laminated lateral ones projecting above the margin; inside smooth, glossy, yellow, margin plain, beneath which is a punctured line; length an inch and a quarter, breadth somewhat more.

Lin. Trans. vol. viii. tab. 1, fig. 9.

First described as British by Dr Pulteney, who found it at the north shore at Poole, and at Weymouth, Dorsetshire.

Radula,

13. *Radula.* Shell convex, sub-orbicular, white, beset with numerous fine sharp-edged concentric striæ; beak central, small, the apex turned to one side; hinge with two small teeth in each valve, standing a little oblique; breadth about an inch and a half, and nearly the same in length.

Brit. Shells, tab. 130. T. Venus Borealis.

Test. Brit. tab. 2. fig. 12.

On the south coast of England, not common. In Scotland, frequent at Leith, Arran, and Zetland.

Bimaculata,

14. *Bimaculata.* Shell roundish, sub-triangular, faintly striated transversely; beak nearly central, the apex turned a little to one side; primary teeth large, lateral ones strong, remote; length half an inch, breadth five-eighths.

Brit. Shells, tab. 19, fig. 1. 1.

First noticed by Da Costa from the coasts of Hampshire and Lancashire. Dr Pulteny and Mr Bryer procured it at Weymouth.

Lactea,

15. *Lactea.* Shell thin, orbicular, convex, with fine concentric irregular wrinkles; beaks small, central, turn-

Bivalves. ing a little to one side; hinge furnished with two teeth in the one valve, and one in the other; by the side of the teeth in each valve a deep groove, into which the connecting cartilage is fixed; diameter three quarters of an inch.

Test. Brit. tab. 2, fig. 4.

Found on various parts of the English coast.

Rotundata, 16. *Rotundata.* Shell thin, sub-pellucid, orbicular, white, rather convex, wrought with fine concentric striæ; beak nearly central, small, turned to one side; teeth two in each valve, one of which is bifid, the other a little diverging; inside smooth, glossy; diameter about an inch.

Test. Brit. tab. 2. fig. 3.

Found on the shores of Dorset, Devon, and Cornwall.

Flexuosa, 17. *Flexuosa.* Shell thin, pellucid, fragile, convex, sub-orbicular; from behind the beak to the lower angle of the margin, a sulcus runs parallel with the cartilage slope, and forms a flexure at the edge; beak nearly central, much produced, turning to one side; hinge with an obsolete tooth; diameter about three-eighths of an inch.

Brit. Shells. tab. 42. fig. 2. Venus sinuosa.

Found in Cornwall and Devon by Mr Montagu; and at Portobello sands by Mr Laskey.

Carnaria, 18. *Carnaria.* Shell sub-orbicular, flattish, with one side rather longer than the other; striated in three directions; beak small, nearly central, and turning a little to one side; hinge in one valve furnished with two small teeth, one of which is bifid, in the other with one tooth; lateral teeth laminated, remote; length three quarters of an inch; breadth seven eighths.

Brit. Shells, tab. 47.

First noticed by Da Costa, from Yorkshire, Devonshire, and Cornwall. Dr Pulteney found it sparingly at Poole and Weymouth.

Maculata, 19. *Maculata.* Shell sub-ovate, strong, striated longitudinally and transversely; irregularly spotted.

Lin. Trans. vol. iii. p. 252.

Found at Tenbigh by Mr Adams.

Polygona, 20. *Polygona.* Shell sub-ovate, sub-orbicular, wrought with fine concentric striæ which are crossed with very fine lines; beak small, the shorter end is a little truncated and angulated; the larger end is rounded; inside smooth, margin uneven; teeth, in one valve, two large and distant, in the other, one, very large, triangular, bifid tooth, with an approximate small one.

Test. Brit. tab. 28, fig. 4.

Dredged up by Mr Laskey off Cramond Island, in the Frith of Forth.

Laskeyi. 21. *Laskeyi.* Shell ovate, oblong, smooth; beak scarcely central, obtuse; one of the sides rounded, the other obtuse; inside white round the margin, and smooth; in one valve there are two approximate sub-bifid teeth, and the margin channeled from the teeth almost to the end of the longest side, and on the other side of the teeth the margin is replicated; the other valve has only a single tooth; length half an inch; breadth three quarters.

Test. Brit. tab. 28, fig. 3.

Found by Mr Laskey in Aberlady bay and Musselburgh sands, in the Frith of Forth.

Genus XXX. Pandora.

XXX. Pandora. *Shell regular, inequivalved and inequilateral, with two oblong, unequal, and diverging hinge-teeth in the superior valve, and two oblong corresponding pits in the other valve; the cartilage interior; two muscular impressions.*

3

Obs. This genus was formed by Lamarck, for the purpose of separating the Linnæan *Tellina inæquivalvis* from a family of shells with which it is very remotely connected. Bivalves.

1. *Inæquivalvis.* Shell oblong, sub-pellucid, white; left valve nearly flat, the other convex, sub-arcuated along the cartilage slope, and extending into a considerable obtuse beak at that end; the other end round; in the flat valve two diverging teeth, the anterior one small; from the beak to the longest side, a longitudinal depression; length half an inch; breadth one inch. Inæquivalvis.

Brit. Shells, tab. 41, fig. 1, *Tellina inæquivalvis.*

First described as British by Mr Donovan. According to Dr Maton and Mr Rackett, small ones are found on the Kentish coast.

Genus XXXI. Corbula.

Shell transverse, inequilateral, inequivalved, with prominent incurved beaks; hinge with a single conical recurved tooth in each valve; ligament internal; two lateral impressions. XXXI. Corbula.

1. *Inæquivalvis.* Shell subtriangular, strong; under valve deep, and larger than the upper valve; beak prominent, standing high above the hinge; outside covered with a brown epidermis; inside smooth, the margin appearing as if ground to an edge; length three-eighths of an inch. Inæquivalvis.

Test. Brit. tab. 26. fig. 7. *Mya inæquivalvis.*

This shell we have ventured to remove from the *Myæ*, and to place in the genus *Corbula* of Lamarck, with the characters of which it seems most exactly to correspond. It is a very common shell on the English and Scottish shores.

Genus XXXII. Cardium.

Shell equivalved, convex, longitudinally ribbed, with a toothed margin; hinge with two teeth near the beak, and a larger remote lateral one on each side, locking into the opposite valve. XXXII. Cardium.

1. *Edule.* Shell with about twenty-six antiquated ribs, of a yellowish-white colour; the anterior end a little elongated, and generally of a darker colour; greatest diameter about an inch and three quarters. Edule,

Brit. Zool. tab. 50, fig. 41.

Brit. Shells, tab. 124.

This is the common cockle, and is found in great plenty on the British shores, in the sandy bays and inlets.

2. *Aculeatum.* Shell convex, posterior side rounded, the other nearly straight, and more elongated at the front marginal angle; ribs about twenty-one, with a depressed line down the middle; the round end beset with large compressed tubercles, the other part towards the margin with spines; length about four inches. Aculeatum,

Brit. Shells, tab. 6.

Common in various parts of the English and Scottish shores. The young of this species have been long known as *Cardium ciliare.* They are destitute of spines.

3. *Echinatum.* Shell very convex, having about eighteen ribs furnished with numerous close set convex spines; diameter about two inches and a half. Echinatum,

Brit. Shells, tab. 107, fig. 1.

Common on our shores.

4. *Lævigatum.* Shell sub-oval, striated longitudinally, with a few concentric wrinkles; anterior side a lit- Lævigatum,

Bivalves.

tle produced; epidermis yellowish-brown; young shells are finely polished; length two inches and a half; breadth two inches.

Brit. Zool. tab. 51, fig. 40.

Found in several places on the coast.

Nodosum, 5. *Nodosum.* Shell rufous white, flat, sub-orbicular, with twenty-four close set obtuse tubercles; inside white, glossy; diameter three quarters of an inch.

Test. Brit. p. 91.

Discovered in Falmouth, in Cornwall, by Mr Montagu.

Elongatum, 6. *Elongatum.* Shell compressed, suboval, subangulated, with twenty-one ribs faintly wrinkled and rounded; posterior side somewhat elongated and angulated; diameter a quarter of an inch.

Test. Brit. page 82.

Found by Mr Montagu by dredging in Salcomb-bay.

Exiguum, 7. *Exiguum.* Shell convex, sub-triangular, with twenty tuberculated ribs, the interstices strongly striated transversely; length about half an inch.

Brit. Shells, tab. 82, fig. 3.

Found by Mr Montagu in Cornwall and Devon; Mr Boys has found it at Sandwich; Mr Laskey found it at Dunbar; and we have it from Zetland.

Medium 8. *Medium.* Shell sub-triangular, sub-cordated, with about thirty-six smooth ribs; truncated on one side, and running into an angle at the front margin; the other side is shorter, and rounded; primary teeth one in each valve, which, with the lateral ones, are strong and elevated; length about an inch.

Brit. Shells, tab. 32, fig. 1.

First described as British by Mr Montagu, whose specimen was found at Hartlepool, on the coast of Durham.

Rubrum, 9. *Rubrum.* Shell smooth, red, glossy, pellucid, convex; hinge not quite central; rounded at both ends; beak prominent; hinge with nearly obsolete primary teeth, lateral ones very conspicuous; diameter about the eighth of an inch.

Test. Brit. tab. 27, fig. 4.

Found by Mr Montagu on the coast of Devon, and at Dunbar by Mr Laskey.

Discors, 10. *Discors.* Shell convex, sub-orbicular, glossy, white, finely striated in an oblique direction, the striæ curved at the anterior side, the posterior end in a contrary direction, forming an acute angle with the others; beak small, central, turning a little to one side; size of a pea.

Test. Brit. page 84.

Found by Mr Montagu at Falmouth.

Muricatulum, 11. *Muricatulum.* Shell white, opake, heart-shaped, with a muricated margin; minute.

Test. Min. Rar. fig. 84.

Found at Sheppy island.

Arcuatum, 12. *Arcuatum.* Shell thin, fragile, semi-pellucid, orbicular, white, finely striated transversely in an arcuated manner, with a few concentric wrinkles; beak central, pointed at the apex, and turned to one side; hinge, with one primary tooth in each valve; laminated teeth remote; diameter about half an inch.

Test. Brit. tab. 3, fig. 2.

Dredged up in Falmouth harbour by Mr Montagu.

Edentula, 13. *Edentula.* Shell sub-ovate, thin, rounded at one end, and sub-angulated at the other, with a few broad, distant, concentric elevations and longitudinal striæ; beak small pointed; hinge destitute of any primary tooth; length two inches and a half; breadth three inches.

Brit. Shells, tab. 161, *Mactra radiata.*

Found by Mr Laskey at Portsmouth after a storm.

Fasciatum. 14. *Fasciatum.* Shell sub-orbicular, sub-pellucid, with about twenty seven smooth, glossy, flattened ribs, slightly tuberculated at the shorter side; coloured with three or four brown bands; length three-eighths of an inch.

Test. Brit. tab. 27, fig. 6.

Found on the shores of Cornwall, Devon, Leith, and Zetland.

Genus XXXIII. Cyclas.

XXXIII. Cyclas. *Shell almost orbicular, or a little transverse, not inflected on the fore part; the hinge with two or three teeth, and two lateral ones, compressed and rather remote.*

Obs. This genus of Lamarck contains species which chiefly inhabit rivers and pools. The British species have been referred to the genus *Cardium* or *Tellina.* Their smooth surface and uneven margin forbid their insertion in the former, and the want of the fold in the anterior part of the shell, forbid their insertion in the latter genus. The inhabitant bears a close resemblance to the molluscous genus *Tethys.* The three species are viviparous.

Cornea, 1. *Cornea.* Shell thin, pellucid, sub-orbicular, convex, marked with fine concentric striæ; epidermis horn-coloured; beak central, obtuse; hinge with the central teeth very small; the lateral laminated ones remote and prominent; sometimes half an inch long, and three quarters broad.

Brit. Zool. tab. 49, fig. 36, *Tellina cornea.*
Brit. Shells, tab. 96.
Test. Brit. p. 86, *Cardium corneum.*

A common British shell, found in slow rivers and stagnant pools.

Amnica, 2. *Amnica.* Shell thin, sub-pellucid, oblique, suboval, convex, sulcated transversely, and striated longitudinally towards the front; umbo placed nearest to one side; hinge furnished with one central tooth, and two lateral teeth on each side, in one valve, standing parallel one within the other, the outer of which is very small; in the other valve two approximating primary teeth stand oblique, with one lateral tooth on each side; epidermis horn-coloured; length three-eighths of an inch; breadth half an inch.

Brit. Shells, tab. 63. fig. 2, *Tellina rivalis.*

First distinguished as British by Dr Maton. It is a common British shell, inhabiting the same places as the preceding, resembling the above in shape.

Lacustris. 3. *Lacustris.* Shell sub-rhomboidal, thin, pellucid, smooth, of a pale horn-colour, rather compressed round the margin; umbo central, small, but extremely prominent, giving a cordiform appearance to the lateral aspect of the shell; in each valve a primary tooth, one of which is plain, the other bifid; length three-tenths of an inch.

Test. Brit. page 89, *Cardium lacustre.*

First observed as British by Mr Swainson, in a river near Bulstrode; and since, in several places in England by Mr Montagu.

Genus XXXIV. Mactra.

XXXIV. Mactra. *Shell equivalve, inequilateral, transverse, a little gaping at the sides; the hinge tooth complicated, with an adjacent little pit; the lateral teeth remote, compressed, and inserted; ligament internal, inserted in the pit of the hinge.*

Bivalves.

Solida,

1. *Solida.* Shell strong, sub-triangular, of a yellowish-white colour, with a few concentric ridges; sides nearly equal; lateral teeth large, prominent, crenated within; length an inch and a half, breadth an inch and three quarters.

Brit. Zool. tab. 52. fig. 43.
Brit. Shells. tab. 61.

A common shell on all the coasts.

Truncata,

2. *Truncata.* Shell triangular, strong, thick, and nearly smooth; umbo central, large, and very prominent; sides equal, much flattened, and truncated; the front margin rounded; length an inch and a half, breadth an inch and three quarters.

Brit. Shells, tab. 126. M. subtruncata.

Common on all the coasts.

Subtruncata,

3. *Subtruncata.* Shell strong, sub-triangular, transversely striated, rounded on one side, the other more pointed and longer; umbo large and prominent, the sides near the beak much turned inwards, especially the anterior, which is depressed into a cordiform shape when the whole shell is viewed sidewise; length three quarters of an inch, breadth an inch.

Test. Brit. tab. 27. fig. 1.
Brit. Zool. tab. 52. fig. 42. M. stultorum.

Equally common with the preceding species.

Stultorum,

4. *Stultorum.* Shell thin, sub-triangular, semi-pellucid, faintly striated transversely, irregularly rayed longitudinally with broad and narrow whitish lines; umbo central, prominent, sides nearly equal; length an inch and three quarters, breadth two inches and a quarter.

Brit. Zool. tab. 49. fig. 30. Tellina radiata.

Common on all the British shores.

Cinerea,

5. *Cinerea.* Shell thin, sub-triangular, truncated, and of a cinereous colour; beak large and very prominent, slightly turned to one side, beneath which there is a depression; opposite side much compressed laterally; inside pale, with a tinge of blush.

Test. Brit. p. 35.

Found by Mr Bryer on the coast at Weymouth.

Dealbata,

6. *Dealbata.* Shell thin, fragile, pellucid, oval, white, very finely striated, with a few coarser concentric wrinkles; the smaller end gaping a little; umbo nearest the larger end; middle tooth in one valve broad, bifurcated, angulated close to the beak; lateral teeth not very remote; inside glossy white, moderately concave; margin plain, with a sharp edge; length an inch, breadth an inch and a half.

Test. Brit. tab. 5. fig. 1.

First noticed as British by Dr Pulteney, who received it from Mr Bryer at Weymouth.

Triangularis,

7. *Triangularis.* Shell white, opake, strong, sub-triangular; beak prominent, obtuse; sides a little unequal; hinge strong, primary teeth in one valve large bifid, in the other two small teeth, with a triangular cavity between; lateral teeth depressed; margin strongly crenated; length one-eighth of an inch, breadth rather less.

Test. Brit. tab. 3. fig. 5.

Found by Mr Montagu in Falmouth harbour, and on the coast of Devon.

Minutissima,

8. *Minutissima.* Shell white, nearly smooth, sub-triangular; umbo prominent; inside smooth, margin plain; hinge strong; primary teeth in one valve two, separated by a cavity for the reception of a single large tooth in the opposite valve.

Test. Brit. p. 37.

Found by Mr Montagu on a new species of coralline, in company with *Pecten fragilis.*

Glauca.

9. *Glauca.* Shell oval, of a dirty white colour, very finely striated transversely, and marked with broad and narrow glaucous rays; the anterior end wrinkled; the beaks reflect backwards, with a narrow gape between them; length two inches and a half, breadth three inches and a half.

Brit. Shells, tab. 125.

Found by Miss Pocock on Hale sands, under Lelant, Cornwall.

Genus XXXV. Lutraria.

XXXV. Lutraria.

Shell transverse, inequivalved, gaping at the extremities; two oblique diverging hinge teeth accompany a large pit for the reception of the ligament; no lateral teeth.

Vulgaris,

1. *Vulgaris.* Shell oblong-oval, gaping a little at both ends, yellowish-white, with irregular concentric striæ; umbo small, placed near to one side, from which the shell slopes a little; tooth in one valve triangular; length two inches and a half, breadth five inches.

Brit. Shells, tab. 58. Mactra lutraria.

Common on many parts of the coast, especially at the influx of rivers.

Hians,

2. *Hians.* Shell strong, rugose, oblong, with concentric wrinkles; umbo small, margin next to the hinge sub-arcuated; inside white, with a strong elevated ridge along the upper side of the cicatrix; the longer end with a considerable gape; length two inches and a quarter, breadth five inches.

Brit. Shells, tab. 140. *Mactra hians.*

Frequent on the English coast.

Genus XXXVI. Donax.

XXXVI. Donax.

Shell equivalved, inequilateral, anterior margin obtuse; the hinge teeth two, either in one or both valves; the lateral teeth one or two, rather distant.

Trunculus,

1. *Trunculus.* Shell oblong, smooth, glossy, finely striated longitudinally, covered with a thin epidermis; umbo small, placed nearest to the lesser end; margin crenated; length five-eighths of an inch, breadth an inch and a half.

Brit. Zool. tab. 55. fig. 45.
Brit. Shells, tab. 29. fig. 1.

On most of the sandy British shores.

Denticulata,

2. *Denticulata.* Shell strong, thick, sub-cuneiform, striated longitudinally; the interstices punctated; large end much sloped and truncated, with a prominent ridge upon the angle of the slope; hinge with strong teeth; margin denticulated; length about six-eighths of an inch, breadth an inch.

Brit. Zool. tab. 55. fig. 46.
Brit. Shells, tab. 24. D. crenulata.

A rare British species, said to be found by Dr Pulteney and by Mr Breyer at Weymouth.

Complanata,

3. *Complanata.* Shell oblong, smooth, and glossy, of a light yellow or faint purplish colour, with spots or streaks of white, and one broad ray from the beak to the margin; umbo placed nearest to one end; teeth small, margin plain; length five-eighths of an inch, breadth an inch and a quarter.

Test. Brit. tab. 5. fig. 4.

Found by Mr Montagu on the coast of Devon. It likewise inhabits the Cornwall and Dorset coasts.

Plebeia,

4. *Plebeia.* Shell thick, strong, oblong, sub-oval, of a dull horn colour, smooth and glossy, generally marked with two brown stripes longitudinally from the beak, which is placed nearest to one side; margin plain; length about half an inch, breadth three quarters.

Test. Brit. tab. 5. fig. 2.

First found at Weymouth by the Duchess of Portland, and since at the same place by Mr Bryer. Also at Dunbar by Mr Laskey.

Bivalves.

Irus,

5. *Irus.* Shell sub-oval, opake, rugose, with high concentric membranaceous ridges, reflecting upwards, broken or undulated; interstices finely striated; umbo small, placed near one side; apex much turned; teeth small, bifid; margin plain; length half an inch, breadth three quarters.

Brit. Shells, tab. 29. fig. 2.

Found frequently on the western coast of England burrowed in limestone.

Castanea,

6. *Castanea.* Shell strong, glossy, chesnut-coloured, furnished with a few irregular transverse wrinkles; a ray of chesnut runs from the beak to the opposite margin, in a curved direction; beak obtuse, inclining to the anterior side; one large and one small tooth in each valve; no lateral teeth; margin plain; length a quarter of an inch, breadth three-eighths.

Test. Brit. tab. 17. fig. 2.

Discovered by Mr Montagu in St Austle's bay, Cornwall; and found by Mr Laskey at Dunbar.

Rubra,

7. *Rubra.* Shell smooth, of a reddish colour, cuneiform, truncated at one end; beak obtuse; inside of the same colour; margin plain; hinge with two teeth in each valve, placed angularly, and approximating at the beak; very minute, not a line in length.

Test. Brit. Sup. p. 38.

Discovered by Mr Montagu among *Corallines*, in deep water.

XXXVII. Venus.

Genus XXXVII. Venus.

Shell equivalve, the frontal margin flattened with incumbent lips; hinge with three approximate and diverging teeth.

Paphia,

1. *Paphia.* Shell strong, flattened, sub-orbicular, with several elevated broad concentric ridges variously coloured; beak central, much turned to one side, beneath which is a cordiform depression; hinge with strong teeth; margin crenulated; length and breadth about an inch.

Brit. Shells, tab. 170.

Found on the British shores from Cornwall to Zetland.

Verrucosa,

2. *Verrucosa.* Shell strong, thick, heavy, sub-orbicular, convex, with numerous strong elevated ridges, somewhat recurved and broken at the ends; umbo turned much to one side, beneath which is a cordiform depression; cartilage slope of the right valve turns inwards, slightly striated longitudinally and marked transversely with brown streaks; margin crenated; diameter about two inches and a quarter.

Brit. Shells, tab. 44.

Brit. Zool. tab. 54. fig. 48. *Venus Erycina.*

Common on many of the British shores.

Laminosa,

3. *Laminosa.* Shell ovate, with concentric thin laminal ridges, very little reflected; striated in a longitudinal direction between the ridges at the umbonal region; beak pointed inclining to one side with a cordiform depression; hinge with four teeth in each valve; margin finely crenated; length about an inch, breadth an inch and a quarter.

Brit. Shells, tab. 115.

Mem. Wer. Soc. vol. i. tab. 8. fig. 16.

Found on the coast of Devonshire by Mr Montagu, and in the Frith of Forth by Mr Laskey.

Striatula,

4. *Striatula.* Shell strong sub-cordated with numerous fine prominent recurved concentric striæ; yellowish, rayed with rufous brown, and frequently marked with fine zigzag streaks of the same colour; umbo turns to one side, beneath which is a cordiform depression; cartilage slope much depressed, faintly striated; margin crenated; length an inch, breadth an inch and a quarter.

Brit. Zool. tab. 56. fig. 50.

Brit. Shells, tab. 68.

In sandy bays frequent in company with the common cockle.

Islandica,

5. *Islandica.* Shell strong, thick, sub-orbicular, convex, white, with a dark brown epidermis; wrought with fine irregular concentric striæ; beak pointed, turned inwards, and curved to one side; no depression; margin plain; length three inches and three quarters; breadth four inches and a quarter.

Brit. Zool. tab. 53. fig. 47. *V. mercenaria.*

Brit. Shells, tab. 77.

Common on the British shores. From the Frith of Forth, we have seen one which was 13 inches in circumference, and weighed nine ounces and a half. At St Andrews' they are called *Dakies*, and in Zetland *Cuvies*.

Chione,

6. *Chione.* Shell strong, sub-cordated, wrinkled concentrically, covered with a very smooth glossy chesnut coloured epidermis more or less radiated with a darker shade; umbo placed nearest to one end, with the apex turned sidewise, beneath which is a strong cordiform depression; margin plain; length three inches, breadth three inches and three quarters.

Brit. Shells, tab. 17.

Not uncommon on the Cornish coast, where they are called *Queens*, more rare on the Dorset and Cheshire coasts.

Exoleta,

7. *Exoleta.* Shell strong, orbicular, with fine close-set, thread-like, concentric striæ, with a few obsolete ridges; umbo much turned to one side, beneath which is a short much depressed cordiform depression; margin plain; diameter two inches.

Brit. Zool. tab. 54. fig. 49.

Brit. Shells, tab. 42. fig. 1.

Not uncommon on the British shores.

Undata,

8. *Undata.* Shell orbicular, thin, white with fine concentric irregular striæ, which sometimes run into uneven wrinkles; umbo prominent, apex pointed and turning to one side; no depression; inside smooth, concave; margin plain; edge acute, and somewhat undulated; length an inch and a quarter, breadth an inch and a half.

Brit. Zool. tab. 55. fig. 51.

Not unfrequent on the British shores.

Tigerina,

9. *Tigerina.* Shell suborbicular, flat, lenticular, thin, white, striated longitudinally and minutely striated transversely; beak small, pointed and turning a little to one side; margin plain; diameter about three quarters of an inch.

Test. Brit. tab. 4. fig. 1.

First ascertained to be English by Dr Maton, who found it on Studland beach, Dorsetshire, on the North shore, Poole, and at Weymouth.

Sinuosa,

10. *Sinuosa.* Shell thin, convex, with a very deep obtuse sinus, or bending, on the front.

Brit. Zool. tab. 55. fig. 51. A.

Figured by Pennant from the Portland Cabinet. An uncertain species.

Ovata,

11. *Ovata.* Shell sub-oval, opake, somewhat compressed, with strong longitudinal ribs, transversely striated; umbo nearly central, apex turning a little to one side, beneath which is a subcordiform depression turning a little to one side; margin finely crenated; length three-eighths of an inch, breadth half an inch.

Brit. Zool. tab. 56. fig. 56.

Pult. Dorset. tab. 1. fig. 15.

Bivalves.

First figured by Pennant. Found in England on the British and Devonshire coasts, and at Falmouth in Cornwall. In Scotland in the Frith of Forth, Cromarty and Zetland.

Minima,

12. *Minima.* Shell sub-orbicular a little compressed, flesh coloured, and glossy with broad concentric striæ; from the beak two white lines, in shape like the letter V, run half way down the shell; umbo prominent, pointed, and a little turned to one side; inside glossy white; margin plain; length a quarter of an inch; breadth rather more.

Test. Brit. tab. 3. fig. 3.

Dredged up at Falmouth harbour by Mr Montagu.

Subcordata,

13. *Subcordata.* Shell white, cordate, with strong longitudinal costated striæ, with remote transverse ridges, making the depressions between in the shape of a long square; beak nearest one end, incurvated; anterior side almost straight and much sloping from the beak; margin subcrenated; diameter a quarter of an inch.

Test. Brit. tab. 3. fig. 1.

Found by Mr Montagu in sand from Falmouth harbour.

Granulata,

14. *Granulata.* Shell thick, sub-orbicular, strongly reticulated, of a white colour, with spots and streaks of a brown colour; umbo much turned to one side, beneath which is a cordiform depression; margin crenated; length seven-eighths of an inch, breadth one inch.

Brit. Shells, tab. 83.

Found at Cornwall; Mr Donovan. At Falmouth harbour by Mr Montagu.

Deflorata,

15. *Deflorata.* Shell oblong, sub-oval, thin, tinged with purple, with undulated longitudinal striæ and a few transverse wrinkles; beak placed a little to one side, not very pointed; hinge with two teeth in each valve; length an inch, breadth an inch and three quarters.

Brit. Zool. tab. 57. fig. 54.
Test. Brit. tab. 3. fig. 4.

First described as British by Pennant. Found at Falmouth by Mr Montagu.

Decussata,

16. *Decussata.* Shell sub-rhomboidal; strongly reticulated; cut off diagonally at the anterior end, at which part it is most strongly reticulated; umbo nearest to one end, apex turned to one side, beneath which is a slight lanceolate cordiform depression; hinge with three teeth in each valve, one of which is small, and in one valve is almost obsolete; length two inches, breadth three inches.

Brit. Zool. tab. 57. fig. 53.
Brit. Shells, tab. 67.
Lin. Trans. vol. viii. tab. 2. fig. 6.

Common on many parts of the coast.

Pullastra,

17. *Pullastra.* Shell resembles the last in shape, longitudinal striæ fine with concentric wrinkles; cicatrix broad and divided from the border; length about an inch and a quarter, breadth two inches.

Lin. Trans. vol. viii. tab. 2. fig. 7.
Lin. Trans. vol. vi. tab. 17. fig. 13, 14. (Wood.)

First separated from the preceding by Mr Wood. Common on the English and Scottish coasts. In Devonshire it is called *pullit*, and in Zetland *cullcock*.

Perforans,

18. *Perforans.* Shell sub-rhomboidal, concentrically striated; running into strong wrinkles at the anterior side; umbo near one end, and turned a little sidewise; hinge with three teeth in each valve, one of which is small, the others long slender, and curve outwards; length three eighths of an inch, breadth five eighths.

Test. Brit. tab. 3. fig. 6.

Discovered by Mr Montagu burrowed in limestone at Plymouth. It is likewise found in several places on the Scottish coast.

Virginea,

19. *Virginea.* Shell strong sub-oval, transversely striated, interrupted in a few places by a deeper furrow; umbo placed much to one side, beneath which is a lanceolate cordiform depression; hinge with three teeth in each valve, the outer ones diverging, middle ones bifid; margin plain, edge obtuse; length an inch and a half, breadth two inches.

Brit. Zool. tab. 55. fig. without number. V. rhomboides.
Lin. Trans. vol. viii. tab. ii. fig. 8.

Common on the English coasts. The specimen from which the above dimensions were taken we found in Zetland.

Aurea,

20. *Aurea.* Shell subcordated, moderately strong, rounded at both ends like the last, striated transversely, and marked with faint longitudinal striæ; umbo placed near to one end, small pointed, turned to one side, with a cordiform depression; valves concave; hinge furnished with three teeth in each valve, the middle one bifid; length commonly about an inch, breadth an inch and three eighths.

Brit. Zool. tab. 67. fig. 34, *Tellina rugosa.*
Lin. Trans. vol. viii. tab. 2. fig. 9.
Pult. *Dorset.* tab. 13. fig. 3, *V. Nebulosa.*

On the English shores frequent; found likewise by Mr Laskey in the Frith of Forth.

Sulcata,

21. *Sulcata.* Shell sub-triangular, smooth, obsolete wrinkles; umbo very prominent and large, turning a little to one side, beneath which is a lanceolate cordiform depression; cartilage slope depressed; margin crenated; hinge in one valve of three teeth, the middle one much larger than the others; length seven-eighths of an inch.

Lin. Trans. vol. viii. tab. 2. fig. 2.

From the north of Scotland. (Mr Swainson.)

Triangularis,

22. *Triangularis.* Shell strong, sub-triangular, yellowish-white, with a few obsolete concentric ridges; umbo central, prominent, and turned a little to one side; each side slopes nearly equal; a lanceolate cordiform depression; hinge in one valve furnished with two strong teeth, one running backwards parallel with the cartilage slope, bifid; margin plain; length half an inch, breadth nearly the same.

Test. Brit. tab. 17. fig. 3.

Found by Mr Montagu on the coast of Devon.

Spinifera,

23. *Spinifera.* Shell sub-triangular, with numerous concentric equidistant ridges at the anterior end, becoming confluent, and forming short obtuse reflected spires; beak central, and turned a little to one side; hinge with a single primary tooth, and a small cavity on each side receiving two teeth from the opposite valve; margins plain; length half an inch, breadth a little more.

Test. Brit. tab. 17. fig. 1.

Discovered by Mr Montagu in a heap of sand from Salcomb-bay, Devonshire.

Reflexa,

24. *Reflexa.* Shell sub-orbicular, with thin laminal reflected ridges, and fine longitudinal striæ; hinge furnished with three strong teeth in each valve, the middle one of which is sub-bifid; margin finely crenulated; diameter about an inch.

Mem. Wer. Soc. vol. i. tab. 8. fig. 1.

Discovered in the Frith of Forth by Mr Laskey. Mr Montagu has found it on the coast of Devon.

Orbiculata,

25. *Orbiculata.* Shell white, depressed, orbicular,

Bivalves.

cancellated; beak very small, with a minute cordiform depression; inside white; margin plain; teeth, two, primary, approximate, and one remote, standing transverse; the margin where the lateral tooth is placed projects into an angle; diameter five-eighths of an inch.

Test. Brit. tab. 29. fig. 7.

Found on the shore near Dunbar by Mr Laskey.

Dysera,

26. *Dysera.* Shell sub-ovate, sub-cordate, with distant concentric, elevated, and reflected ridges, the interstices coarsely striated in a longitudinal direction; beak small and much reclined; hinge furnished with three teeth in each valve; margin crenulated; diameter not quite three quarters of an inch.

Lister's *Conch.* tab. 277, 278.

Found in the Frith of Forth by Mr Laskey.

Compressa,

27. *Compressa.* Shell strong, thick, sub-orbicular, compressed, and slightly sulcated; epidermis yellowish-brown; beak prominent, turned to one side, with a small lanceolate cordiform depression; margin flat; diameter rarely an inch.

Test. Brit. tab. 26. fig. 1. 1. 1.

Found by Mr Laskey at Dunbar. We have observed it in the Murray Frith and in Zetland.

Scotica,

28. *Scotica.* Shell thick, sub-cordated, sub-compressed, with many regular, parallel, transverse ridges; epidermis brown; beak reclined; depression lanceolate; inside white, glossy; teeth strong, oblique; margin plain; length nearly three quarters of an inch, breadth nearly an inch.

Lin. Trans. vol. viii. tab. 2. fig. 3.

Found by Mr M'Leay on the coast of Caithness: we have found it in Zetland, the Murray Frith, and the island of Arran.

Danmonia,

29. *Danmonia.* Shell thick, transversely ovate, sub-compressed, and furrowed with many equidistant strong concentric ridges, which, with the intermediate sulci, are quite smooth; epidermis brown; beak nearly central and somewhat reclined; cartilage slope linear; depression cordiform; margin crenulated; length an inch, breadth an inch and a quarter.

Test. Brit. tab. 29. fig. 4.

Found by Mr Montagu in deep water off the coast of Devon, and by Mr Laskey in the Frith of Forth. Nearly allied to the preceding species.

Lactea,

30. *Lactea.* Shell thick, heavy, lentiform, somewhat compressed, with thick, elevated, obtuse concentric striæ, and slightly truncated anteriorly.

Brit. Shells, tab. 149.

On the western coast of England, (Mr Donovan,) and on Tyningham sands, near Dunbar, by Mr Laskey.

Cassina,

31. *Cassina.* Shell thick, with brown lines, furnished with numerous transverse, recurved, acute laminæ; the posterior margin crenulated and grooved behind the beak; umbo reddish; depression brown; diameter an inch and a half.

Lin. Trans. vol. viii. tab. 2. fig. 1.

Found by Mr M'Leay on the coast of Caithness, and by Mr Neill in Orkney.

Guincensis,

32. *Guincensis.* Shell sub-cordate, with numerous close regular sharp ridges; colour cinereous, with two or three rays of purplish-brown running from the umbo; the cordiform and cartilage depression purple; margin plain; length an inch and a quarter, breadth one inch and a half.

Test. Brit. page 48. *Sup.*

Found by Mr Laskey off St Abb's Head, and by Mr Bryer at Weymouth.

Substriata,

33. *Substriata.* Shell transversely ovate, sub-pellucid, white, concentrically wrinkled, and obsoletely wrought with undulated longitudinal striæ; beak near one end small, turning towards the shortest side; margin plain; length half an inch.

Test. Brit. tab. 29. fig. 6.

Found by Mr Laskey off the isle of May in the Forth.

Subrhomboidea.

34. *Subrhomboidea.* Shell sub-rhomboidal, rounded at one end, and truncated at the other, and irregularly wrinkled concentrically, especially towards the margin, where the ridges are prominent but obtuse; margin plain behind the teeth, projecting inwards; length half an inch, breadth three quarters.

Test. Brit. tab. 28. fig. 2.

Found by the same gentleman with the preceding species.

Genus XXXVIII. Isocardia.

XXXVIII. Isocardia.

Shell heartshaped, with separated, involuted, and diverging beaks; the hinge formed by two flattened cardinal inserted teeth, and an isolated lateral tooth under the cartilage slope.

Cor.

1. *Cor.* Shell sub-globose, thick, strong, nearly smooth, or slightly wrinkled transversely, covered with a yellowish-brown epidermis; beaks large, prominent, incurvated, not touching when the valves are closed; hinge strong; teeth flattish; inside smooth, white; margin plain; diameter three inches.

Brit. Shells, tab. 134. *Chama Cor.*

Mem. Wer. Soc. vol. i. tab. 8. fig. 7.

Found near the North Foreland by Mr Swainson, on the shores of the Hebrides by Mr Agnew, and alive off St Abb's Head by Mr Laskey.

Genus XXXIX. Terebratula.

XXXIX. Terebratula.

Shell convex, equilateral, inequivalved, the largest valve produced into an incumbent beak, pierced with a hole, through which a ligament passes by which the shell is affixed; hinge with two cardinal teeth.

Vitrea.

1. *Vitrea.* Shell ventricose, hyaline; front margin a little truncated, concentrically striated or wrinkled, and minutely punctured all over; lower valve with two lateral teeth, from which proceed two horizontal bony spicula with a small tooth towards the base of each, running three-fourths across the shell; upper valve with two lateral bifid teeth, with the beak perforated; length an inch and a tenth, breadth two tenths less.

Found in a fishing boat in Zetland; taken in deep water.

Genus XL. Nucula.

XL. Nucula.

Shell inequilateral, equivalved, sub-triangular, hinge on a bent line, with numerous transverse parallel teeth, and a cardinal tooth in each valve at the angle, not inserted, beaks approximating and turned backwards.

Obs. The genus Arca of Linnæus has been divided into three genera by Lamarck, which, in our opinion, are perfectly distinct and well characterised. The angular hinge of the Nucula, the straight hinge of the Arca, and the arched hinge of the Pectunculus, are marks of distinction too striking and obvious to admit of their union under one genus. They might form a very good section of the dentated divison of bivalves.

Nuclea.

1. *Nuclea.* Shell sub-triangular white, with an olivaceous epidermis, concentrically wrinkled and crossed with numerous minute stria; umbo placed a little to one side, beneath which is a cordiform depression; inside glossy silvery white; hinge angular, beset with

Bivalves.

numerous fine regular pectinated teeth; margin finely crenated; length three-eighths of an inch; breadth somewhat more.

Brit. Shells, tab. 63. Arca nucleus.

Found on the British shores from Zetland to Cornwall.

Minuta, 2. *Minuta.* Shell somewhat oblong, the anterior side running into an angulated beak cut off at the point; finely striated transversely interrupted by three or four strong concentric ridges; umbo very small, beneath, which is a smooth depression; teeth numerous, angulated; a cavity under the apex destitute of teeth; margin plain; length three-eighths of an inch; breadth about half an inch.

Brit. Shells, tab. 78. Arca caudata.

Found by Mr Boys at Sandwich, and at Dunbar by Mr Laskey; it likewise occurs in Zetland.

Rostrata, 3. *Rostrata.* Shell sub-ovate, the smaller end produced into a lip, which is reflected or arcuated, the opposite end rounded; beak small, nearly central, a little reclined; pellucid, horn-coloured, glossy, wrought with very fine regularly transverse striæ; margin plain; length half an inch; breadth three quarters.

Test. Brit. tab. 27. fig. 7.

Found by Mr Laskey in the Frith of Forth.

Tenuis. 4. *Tenuis.* Shell sub-cordate, smooth, white, covered with an olivaceous epidermis; umbo very small; beaks slightly inflected and placed near one end; inside smooth, white, and somewhat nacred; margin thin and entire, hinge pectinated with about fifteen elevated teeth, six on one side and nine on the other, divided by a small concave plate that projects inwards; diameter about a quarter of an inch.

Genus XLI. Arca.

XLI. Arca. *Shell transverse, inequilateral, beaks distant; hinge in a straight line, plain at the ends, and furnished with a row of transverse parallel mutually inserted teeth; ligament exterior.*

Lactea, 1. *Lactea.* Shell rhomboidal, yellowish white, covered with a brown pilous epidermis, under which it is furnished with numerous fine close-set rib-like longitudinal striæ, with a few concentric wrinkles, giving the shell a reticulated appearance; umbo turned to one side; margin crenulated.

Brit. Zool. tab. 58. fig. 59.
Brit. Shells, tab. 135.

On the shores of England and Scotland; not common.

Noæ, 2. *Noæ.* Shell sub-rhomboidal, the smaller end of each valve turning inwards, forming a sharp angle, giving the smaller end of the shell a sub-cordated appearance; umbo placed nearest to one side; apex prominent, shell striated, reticulated; colour rufous brown, inside whitish, or tinged with brown; breadth about half an inch.

Test. Brit. tab. 4. fig. 3. 3.

Found on the British shores, but not frequent.

Fusca, 3. *Fusca.* Shell finely reticulated, of a purplish brown colour, destitute of any markings.

Brit. Shells, tab. 158. fig. 34.

Found on the shores of Cornwall by Mr Donovan, in Devonshire by Mr Montagu, and at Dunbar by Mr Laskey.

Genus XLII. Pectunculus.

XLII. Pectunculus. *Shell orbicular, sub-equilateral, hinge arched, and furnished with a row of oblique, mutually inserted teeth; ligament external.*

Pilosus, 1. *Pilosus.* Shell strong, orbicular, covered with a dark brown pilous epidermis, particularly about the margin; beneath this the shell is coloured with zig-zag lines of chesnut; faintly striated longitudinally, and obsoletely wrinkled transversely; inside white, margin crenated; diameter two inches and a half or more.

Brit. Zool. tab. 58, fig. 68. Arca glycymeris.
Brit. Shells, tab. 37.
Lin. Trans. vol. viii. tab. 3. fig. 3. 4.

Common to Cornwall and Zetland. In Orkney we have observed vast quantities of them thrown ashore, of a very large size.

DIVISION II. TOOTHLESS.

In this division a simple ligament connects the valves, and the hinge is destitute of teeth which lock into one another. It admits of a division into two Sections.

SECTION I. INEQUIVALVE.

The inequivalve shells are in general somewhat irregular in their growth, and have one of the valves larger and more convex than the other.

Genus XLIII. Pecten.

XLIII. Pecten. *Shell eared; beaks contiguous; hinge without teeth; ligament internal, fixed to a triangular cardinal cavity.*

Maximus, 1. *Maximus.* Shell with fourteen or fifteen ribs, longitudinally grooved, and wrought with very fine striæ; upper valve flat, with a depression at the umbo; lower valve convex; auricles striated, equal, rectangular; length five inches, breadth six.

Brit. Zool. tab. 59. fig. 61.
Brit. Shells, tab. 49.

Found on various parts of the British shores.

Jacobæus, 2. *Jacobæus.* Shell with seventeen or eighteen very convex ribs, rounded and striated transversely; a smooth whitish depression at the umbo; lower valve pure white; auricles equal, rectangular, striated; length four inches, breadth five.

Brit. Zool. tab. 60. fig. 62.

First noticed as British by Pennant; found in Dorset, Cornwall, and Yorkshire.

Opercularis, 3. *Opercularis.* Shell sub-orbicular, with about twenty round transversely striated ribs; colour reddish; auricles nearly similar; diameter about two inches and a half.

Brit. Shells, tab. 12. Ostrea subrufus.
Brit. Zool. tab. 60. fig. 63. P. subrufus.

Common on the British shores.

Varius, 4. *Varius.* Shell with twenty-eight echinated ribs; colour various, clouded; upper valve less convex than the other; auricles very unequal; the longest ear on the superior valve much wrinkled, the other striated sidewise; beneath the long ear of the superior valve, a few teeth like laminæ; length two inches and a quarter.

Brit. Zool. tab. 61. fig. 64.
Brit. Shells, tab. 1. fig. 1.

On the English shores frequent; found in Orkney by Mr Neil, and in the Frith of Forth by Mr Sime.

Lineatus, 5. *Lineatus.* Shell sub-orbicular, with eighteen narrow ribs with a red line upon the ridge of each on the upper valve; lower valve white; auricles nearly

Bivalves. equal; length an inch and a half, breadth not quite so much.

Brit. Shells, tab. 116.

Found on several places on the English coast.

Distortus, 6. *Distortus.* Shell distorted, with numerous rib-like striæ; upper valve flattened, the under valve irregular; young shells with concave short spines on the ribs; length two inches, breadth two inches and a half.

Brit. Zool. tab. 61. fig. 65.

Brit. Shells, tab. 34.

Wallace's *Orkney*, p. 44. tab. 1.

Found on several places on the English coast; it likewise occurs in Orkney and Zetland.

Obsoletus, 7. *Obsoletus.* Shell with numerous fine longitudinal striæ; eight or ten of these more prominent than others, at irregular distances; sometimes smooth; valves equal, rather flat; auricles unequal, one very large, striated, the other extremely small; white shell, with minute decussating striæ, giving the shell a shagreen appearance.

Lin. Trans. vol. viii. tab. 3. fig. 5.

On the English and Scottish shores frequent.

Glaber, 8. *Glaber.* Shell with seven rounded rays, not much elevated, with longitudinal striæ; and ears nearly equal and large, one of them reticulated, the other striated; inside marked with twenty-one slender rays, middle ones in fours; length three quarters of an inch.

Test. Brit. tab. 28, fig. 6.

Found in Anglesea by Mr Pennant, and on the Scottish coast.

Lævis, 9. *Lævis.* Shell smooth glossy, slightly wrinkled concentrically; colour whitish; one ear very large, the other small and slightly striated longitudinally; diameter about half an inch.

Test. Brit. p 61. Sup.

Found by Mr Montagu in Falmouth harbour. Pennant marks his shell from Anglesea.

Similis, 10. *Similis.* Shell thin, semitransparent, smooth, beautifully clouded with brown, of a compressed globose form, with unequal ears.

Mem. Wer. Soc vol. i. tab. 8. fig. 8.

Found by Mr Laskey in the Frith of Forth.

Fragilis, 11. *Fragilis.* Shell subovate, oblong, convex, fragile, sub-pellucid, white, wrought with numerous slightly undulated longitudinal striæ, with two or three minutely fine intermediate ones; valves equal inequilateral, one side straight, the other arcuated; auricles equal small; hinge a little oblique; length three quarters of an inch, breadth scarcely half an inch.

Test. Brit. p. 62. Sup.

Found by Mr Montagu on the coast of Devon, intermixed with *sertulariæ*.

Subauriculata. 12. *Subauriculata.* Shell ovate, oblong, pellucid, white, equilateral, equivalve, with small equal angular projections or auricles, wrought with numerous longitudinal striæ that slightly crenate the margin; along the middle are two striæ, that appear more conspicuous than the rest, by being opake, and are equally evident on the inside; length a quarter of an inch, breadth half its length.

Test. Brit. tab. 29. fig. 2.

Found by Mr Montagu with the preceding species, and we have found it in Zetland.

Genus XLIV. Ostrea.

XLIV. Ostrea. *Shell adhering, inequivalve; hinge toothless, with a cardinal oblong transversely striated cavity, to which the ligament is attached; one muscular impression in each valve*

Bivalves. Edulis. 1. *Edulis.* Shell sub-orbicular, rugged, with imbricated membranaceous folds.

Brit. Zool. tab. 62. fig. 70. inf.

The common oyster. Found on many of the British shores. A variety occurs in Salcomb Bay, Devonshire, very thin, with membranaceous plates wrinkled into irregular interrupted ribs; upper valve flat, or rather concave on the top, with a corneus margin, half an inch broad. It is called by the fishermen *Rock Oyster.*

Genus XLV. Anomia.

Shell irregular, one valve flattened, with a perforation near the hinge, through which the animal is immoveably fixed by a testaceous operculum to some other body; hinge a transverse linear prominence on the flat valve, connected under the beak of the opposite valve by a strong cartilage. XLV. Anomia.

1. *Ephippium.* Shell sub-orbicular, irregularly wrinkled, waved, and sinuous; one valve convex, the other flat and perforated, adhering to oysters and other bodies, and taking the impression of their form; inside pearlaceous, glossed with green; diameter sometimes three inches and a half. Ephippium,

Brit Zool. tab. 62. sup. fig.

Brit. Shells, tab. 26.

Test. Min. Rar. tab. 3. fig. 20. young.

This shell is common, adhering to marine bodies. In its young state, it is more thin and membranaceous, and has been termed *A. squamula.*

2. *Aculeata.* Shell thin, compressed, muricated, with interrupted longitudinal striæ, furnished with small concave spines; beak small, turning a little downwards; under valve flat, generally plain, sometimes a little echinated towards the margin, and perforated near the hinge; length nearly half an inch. Aculeata,

Test. Brit. tab. 4. fig. 5.

Common on the roots of *algæ*, from the Zetland Islands to Cornwall.

3. *Undulata.* Shell sub-orbicular, marked with fine, irregular, undulated, longitudinal, rib-like striæ; beak very small, placed near the top, a little surrounded by the margin; under valve flat, perforated; diameter an inch and a half. Undulata,

Brit. Shells, tab. 45. *Ostrea striata.*

Common in the same situations as the *A. ephippium.*

4. *Cymbiformis.* Shell sub-ovate, lengthened, subpellucid, white; the upper valve considerably convex, contracting at the umbo, with a beak incurved upon the other valve; slightly wrinkled transversely; lower valve conforms to the shape of the body, to which it is attached; length about three-tenths, breadth two-tenths. Cymbiformis.

Lin. Trans. vol. viii. tab. 4. fig. 6.

Found by Mr M'Leay on the coast of Caithness. Mr Montagu has found it in Devonshire; and Mr Laskey in the Frith of Forth. We have observed it on the spines of Echinus Cidaris from the coast of Zetland.

A shell occurs frequently at Newhaven, near Edinburgh, in the oyster boats, which we suspect will constitute a new species of this genus, which may be termed *fusca.* Only the convex valves have occurred. These are nearly orbicular, moderately convex, closely covered with small tubercles, or plain, with a few transverse waved lines; opake, of a light brown colour, and glossy within; diameter four-tenths.

SECT. II. EQUIVALVE.

The shells of this Section are more regular in their

Bivalves. shape and form than those of the preceding. The British species divide themselves into two genera, Mytilus and Pinna.

Genus XLVII. Mytilus.

XLVII. Mytilus. *Shell with a hinge marked by a longitudinal furrow; beak towards the shortest end; usually affixed by means of a byssus.*

Edulis, 1. *Edulis.* Shell oblong, somewhat pointed at the beak, sides sloped; anterior side a little angulated; posterior side rather indented; inside blue about the margin, whitish in the middle; teeth like crenulations beneath the beak; length three inches, breadth an inch and a half.

Brit. Shells, tab. 128. fig. 1. 1.
Brit. Zool. tab. 63. fig. 73.

Found in vast beds, fixed by the byssus. The common Mussel.

Ungulatus, 2. *Ungulatus.* Shell smooth, somewhat curved; posterior margin inflected, hinge terminal, bidentated; length four or five inches.

Brit. Shells, tab. 128. fig. 2. 2.

Found on the coast of Cornwall by Miss Pocock, and on Gullon Links, near Haddington.

Incurvatus, 3. *Incurvatus.* Shell resembling *M. edulis,* but broader in proportion to its length; posterior side much incurvated; length an inch and a half, breadth an inch.

Brit. Zool. tab. 64. fig. 74.

Inhabits crevices of rocks on the shore, and the roots of *algæ.* We have taken half a dozen of specimens from the root of one fucus, all of them similar in form, though differing in size. This occurrence supports the opinion, that it is distinct from *M. edulis.*

Pellucidus, 4. *Pellucidus.* Shell thin, pellucid, of a whitish colour, tinged with blue, more or less radiated with deep blue, covered with a yellow epidermis; crenulations beneath the beak small; length about two inches, breadth one inch.

Brit. Zool. tab. 63. fig. 75.
Brit. Shells, tab. 81.

Frequent on the British shores.

Modiolus, 5. *Modiolus.* Shell oblong, sub-oval; posterior side towards the beak extends outwards a little; umbo large and prominent; length six inches, breadth three inches.

Brit. Zool. tab. 66. fig. 77.
Brit. Shells, tab. 23.

A variety occurs with a deep depression under the beak, and which has been termed *M. umbilicatus.* The young of the shell is known by the name of *M. barbatus.* Like the common Mussel, this species is abundant, and is gregarious. It is considered as an excellent bait for the haddock. In Zetland it is called Yogue.

Rugosus, 6. *Rugosus.* Shell oblong, sub-oval, with rugged concentric wrinkles; side next the hinge always rounded, the opposite side sometimes truncated; umbo small, placed near to one end; it usually gapes at one end, and opposite to the hinge; length an inch and a quarter, breadth about half its length.

Brit. Zool. tab. 63. fig. 72.
Brit. Shells, tab. 141.

Found burrowed in limestone, and in the roots of fuci.

Precisus, 7. *Precisus.* Shell oblong, irregular, rugose; hinge close to one end of the shell, which is truncated; beak large and prominent, projecting more in one valve than in the other; length a quarter of an inch, breadth half an inch.

Test. Brit. tab. 4. fig. 2.

Not uncommon among the roots of fuci.

Crista-galli. 8. *Crista-galli.* Shell rude, rugged, compressed, varying much in shape, colour, opake, ferruginous; margin scolloped, or cut into deep irregular notches in both valves, corresponding and mutually inserted; diameter two inches and a half.

Chimn. Conch. tab. 75. fig. 683.

Mr Montagu states, that it is found adhering to the bottoms of ships.

Discors, 9. *Discors.* Shell convex, sub-cordated, pellucid; the posterior and anterior sides ribbed; the middle area plain, or faintly wrinkled transversely; umbo large, prominent, apex much turned to one side; margin crenated on the part where striated; length three eighths, breadth half an inch.

Brit. Shells, tab. 25.

Frequent on the English coast, adhering to the *Ascidia mentula.* In Scotland, where it is common, it is principally found among the roots of *Fucus digitatus* and *Polyscides.*

Discrepans, 10. *Discrepans.* Shell sub-oval, compressed, pellucid, covered with a black epidermis; both sides rounded, the anterior one largest, divided into three compartments, like the preceding species; sometimes an inch and a half in breadth.

Test. Brit. tab. 26. fig. 4.

Found in Wales and Devonshire by Mr Montagu. Not uncommon in the Frith of Forth.

Cygneus, 11. *Cygneus.* Shell thin, fragile, semi-pellucid, oval, wrinkled concentrically, and covered with an olivaceous green epidermis; umbo very small, placed nearest one end; inside glossy, pearlaceous; length two inches and a half, breadth nearly six inches.

Brit. Zool. tab. 67. fig. 78.
Brit. Shells, tab. 55.

Found in England in ponds and stagnant waters.

Anatinus, 12. *Anatinus.* Shell thin, semi-pellucid, oval, of a greener colour than the last, less convex, and the margin at the hinge more prominent, rising into a sort of angulated wing; length two inches, breadth three inches and a half.

Brit. Zool. tab. 68. fig. 79.
Brit. Shells, tab. 113.

Frequent in rivers in England and Scotland.

Avonensis, 13. *Avonensis.* Shell suboval, olivaceous, with concentric wrinkles; size of the preceding, but broader in proportion to its length, and not so much produced at the hinge; posterior side more obtuse; front margin nearly straight, or frequently subarcuated.

Lin. Trans. vol. viii. tab. 3. A. fig. 4.

Found by Mr Montagu in the River Avon, about Lackham in Wiltshire.

Plicatus, 14. *Plicatus.* Shell oblong, truncated on one side, close to the umbo; thin, pellucid, uneven, slightly plicated, beaks small, incurvated, and placed at one end, the opposite end broadest; inside glossy; length half an inch, breadth one inch.

Chimn. Conch. tab. 82. fig. 733. a. b.

Found alive off the Isle of Sky by Mr Laskey.

Decussatus, 15. *Decussatus.* Shell longitudinally ovate, sides equal, finely striated longitudinally, crossed by more minute striæ in a transverse direction, giving it a decussated appearance, when examined under a microscope; inside smooth, nacred; near the front margin a reflected transverse ridge; length one eighth of an inch, breadth not so much.

Test. Brit. p. 69. Sup.

Found by Mr Laskey in sand near Dunbar.

Bivalves.

XLVII. PINNA.

GENUS XLVII. PINNA.

Shell longitudinal, cuneiform, with an acute base; valve gaping in the upper part; hinge without teeth, extending nearly the whole length of the shell; affixed by a byssus.

Pectinata, 1. *Pectinata.* Shell pellucid, thin, brittle, marked with about eleven longitudinal striæ or ribs from the apex to the opposite margin, furnished with concave spines; about one-third of the shell opposite the hinge without ribs; breadth three inches at the gaping end, length six inches and a half, tapering to the apex.

Brit. Shells, tab. 10. *P. muricata.*

Found on the English coast, but not common.

Ingens, 2. *Ingens.* Shell rugged, with irregular concentric wrinkles running lengthwise from the beak to the open side, sometimes breaking into laminæ; hinge straight, turning a little inwards at the apex; on the under side, opposite the beak, concave; length about a foot, breadth seven inches.

Brit. Shells, tab. 152.

Found in Shetland, where they are frequently fished up on the hook by the cod-fihers. Mr Montagu has likewise found them in Salcomb bay, Devonshire.

3. *Muricata.* Shell thin, brittle, semi-pellucid, flesh-coloured, darkest at the smaller end, with ten or twelve broad ribs running longitudinally the whole length, and a few intermediate smaller ones at the narrow end; beset sparingly with concave prickles towards the larger end, principally towards the extremity; length five inches, breadth three inches. Muricata.

Test. Brit. tab. 5. fig. 3.

Found near Weymouth, Dorset, by Dr Pulteney.

ORDER III. MULTIVALVES.

Multivalves.

This order of shells was proposed by Major, under the title Pluvalvia. It includes such testaceous bodies as are composed of more pieces than two. It is by no means a natural division; and hence will only be employed in an artificial system. This order admits of two divisions.

DIVISION I. DENTATED.

In this division we include two genera, which differ widely from each other in external aspect, although they have many points of resemblanee in structure and economy.

XLVIII. PHOLAS.

GENUS XLVIII. PHOLAS.

Shell transverse, composed of two principal valves, open at each end, with small accessory pieces placed on the ligament, or at the hinge; hinge recurved, united by a cartilage, beneath which is an uncurved tooth.

Dactylus, 1. *Dactylus.* Shell striated transversely, and slightly longitudinally; the interior end strongly muricated, extending into a beak and forming a large gape; teeth, one in each valve, projecting inwards, long, curved, flat; the smaller valves are four in number; length an inch and a quarter, breadth four inches.

Brit. Zool. tab. 39. fig. 10.

Brit. Shells, tab. 118.

This shell is very common on the British shores, being found in marl, clay, and wood.

Parvus, 2. *Parvus.* Shell white, rough, longitudinally and transversely striated except at the smaller end; the larger end declines into a kind of muricated beak; hinge reflected, without cells; one plate at the back connected by a membrane to the valves; teeth one in each valve, slender, curved, with a knob at the base; length half an inch, breadth one inch.

Brit. Zool. tab. 4. fig. 13.

Test. Brit. tab. 1. fig. 7, 8.

This shell was first described by Pennant. It has been found also by Mr Montagu at Salcomb on the coast of South Devon.

Crispatus, 3. *Crispatus.* Shell opake, strong, gibbous, suboval, obtuse, and open at both ends; transversely striated; half the shell reticulated, and separated from the plain side by a broad furrow down the middle, extending from the beak to the opposite margin; hinge reflected, smooth, forming a cavity at the anterior end, which is obliquely truncated to the front margin; teeth two, long, flat, curved; length about two inches, breadth three.

Brit. Zool. tab. 40. fig. 12.

Brit. Shells, tab. 62.

On the English and Scottish shores frequent.

4. *Candidus.* Shell thin, whitish, rounded at both ends, and closed at the larger end; striated transversely, and crossed by finer striæ radiating from the beak; a few of the radii at the larger end muricated; tooth in each valve slender incurvated, above which, on the margin of one valve, is an erect toothlike process; length seven-eighths of an inch, breadth two inches and a half. Candidus,

Brit. Zool. tab. 39. fig. 11.

Brit. Shells, tab. 132.

Found on the British shores, but not common.

5. *Striatus.* Shell white, conoid, the larger end strongly reticulated, the rest irregularly striated; at the front margin the lip seems to fold back, and forms a smooth surface on the reticulated part; hinge plate large and suboval; teeth long, slender, and much curved; length half an inch, breadth three quarters. Striatus.

Brit. Shells, tab. 117.

Frequent in the bottoms of ships. It is not ascertained whether it breeds in our seas.

GENUS XLIX. TEREDO.

Shell with two principal hemispheric valves, truncated and open at the end, and two small lanceolate accessory valves remote; hinge with a long incurvated tooth in each valve; tube testaceous, sub-cylindric, flexuous, in which the animal resides but to which it is not attached. XLIX. TEREDO.

Obs. This genus was placed in the order Multivalves by Adanson. It was removed by Linnæus into the order Univalves. Its title to its former situation is now placed beyond a doubt, by the interesting observations of Mr Montagu and Mr Home.

1. *Navalis.* Tube thin, brittle, flexuous, of a whitish colour, lodged in wood; valves white, each furnished with a long flat curved tooth, projecting inwards under the hinge, and a short lateral tooth at the extremity of the hinge. Navalis,

Brit. Shells, tab. 145.

Phil. Trans. part. 2. tab. 12, 13.

This shell, called by Linnæus *calamitas navium*, is found in planks and stakes which have lain in the sea. It often pierces the planks of ships, particularly in warm climates, and soon effectually destroys them.

Multivalves.

DIVISION II. TOOTHLESS.

Toothless Shells.

The shells included in this division are not furnished with teeth at the joints. The valves are either simply united, or are furnished with a connecting ligament. This division will admit of distribution into three Sections.

SECT. I. OPERCULATED.

Operculated.

This Section includes shells which are somewhat conical, and have their opening protected by a testaceous lid or operculum, composed of four plates.

Genus L. Balanus.

L. Balanus.

Shell conical, fixed by its base, and composed of six articulated valves; the opening closed by an operculum formed of four valves.

Communis, 1. *Communis.* Shell strong, rugged, with unequal compartments longitudinally costated; valves of the lid pointed, transversely striated, with a longitudinal groove on the two longest; diameter at the base sometimes an inch, height nearly three quarters.

Brit. Zool. tab. 37, fig. 4. 6.

Brit. Shells, tab. 30, fig. 1.

Common on the British shores, adhering to rocks, stones, and old shells.

Balanoides, 2. *Balanoides.* Shell with six compartments, divided by a deep longitudinal furrow; mouth large; lid obtuse; the upper valves slightly striated transversely, the others smooth; diameter about a quarter of an inch.

Brit. Shells, tab. 36, fig. 2, 3.

Common on shells and rocks.

Punctatus, 3. *Punctatus.* Shell with indistinct compartments frequently punctured over; lid of four valves, with a few striæ, the edges of the superior and inferior valves closely united at the top, and indented; diameter about a quarter of an inch.

Test. Brit. tab. 1. fig. 5.

Common on rocks and stones.

Rugosus, *Rugosus.* Shell cylindric, usually divided into six compartments, which become broad towards the top; mouth large; inside margin ridged transversely; lid composed of four rough angulated pointed valves, not striated; diameter about three quarters of an inch.

Lin. Trans. vol. viii. tab. 1, fig. 5.

Not unfrequent on the British shores.

Clavatus, 5. *Clavatus.* Shell long, clavated, slender at the base, dilated at the top, and usually cloven into six divisions; compartments six, three wide, and three narrow, wrinkled longitudinally, and faintly striated transversely; length two inches, diameter at the base three-eighths of an inch.

Ellis's *Zoophytes,* tab. 15, fig. 7, 8.

Found at Weymouth, Dr Pulteney.

Tintinnabulum, 6. *Tintinnabulum.* Shell strong, divided into six raised and six depressed compartments; the former running to a point upwards, and striated longitudinally; the latter contracting to a point downwards, and transversely striated; mouth nearly as large as the base; length an inch and a half.

Brit. Shells, tab. 148.

Pult. Dorset. tab. 1, fig. 5.

This species was first given by Da Costa, but is probably a native of warmer climates, being brought to us on the bottoms of ships.

Costatus, 7. *Costatus.* Shell somewhat conic, ribs equidistant, and diverging from the aperture; operculum sharp pointed.

Brit. Shells. tab. 30. fig. 2.

Discovered by Mr Adams on the coast of Pembroke, and first described by Mr Donovan.

8. *Conoides.* Shell conic, valves smooth, pointed at the apex; aperture very small. Conoides,

Brit. Shells, tab. 30, fig. 3.

Found by Mr Bryer of Weymouth, and first described by Mr Montagu.

9. *Striatus.* Shell compressed; compartments strongly ribbed in an oblique direction to each other, and finely striated across the ribs; margin of the base irregularly serrated; aperture oblique, closed by a lid, and so obscured, that it is scarcely discernible; diameter a quarter of an inch. Striatus,

Brit. Zool. tab. 38, fig. 7.

Brit. Shells, tab. 36, fig. 1.

Common on the British shores, adhering to shells and to the roots of algæ.

10. *Spongeosus.* Shell ovate, with six angulated wrinkled compartments, terminating in much elevated points, and furnished with numerous spines; base concentrically wrinkled, beneath which is a cup rounded at the bottom, whose margin corresponds with the circumference of the base; lid of four valves, the posterior pair long and hooked forward, the anterior pair rough, with decussated striæ; length about half an inch. Spongeosus,

Test. Brit. tab. 17. fig. 4, 5, 6.

Found by Mr Bryer of Weymouth imbedded in a particular species of sponge resembling *Spongia tubulosa.*

In a piece of the same species of sponge from the coast of Devon, Mr Montagu found another species allied to the preceding. It was mutilated, but enough remained to point out some of its peculiar characters. The cup or base was in the form of an inverted cone, perforated at the smaller end, thick, margin of the cup bevelled off to an edge, which is striated; inside furnished with annular ridges, and lined with a membrane; outside rough, with tubercles and broad projecting plates.

In our opinion, the *Balanus spongeosus* ought to form a new genus, as it differs in character and economy from all the other species of the genus Balanus.

Genus LI. Coronula.

Shell regular, sub-rotund, sub-conical, divided into twelve areæ, with an opening both in the inferior and superior part; superior opening closed by a four-valved lid.

Obs. The shells of this genus, together with their inhabitants, are found imbedded in the fat of the whale, so as to leave only the superior aperture uncovered.

1. *Diadema.* Shell with six depressed, flat, transversely striated compartments, and six prominent ones, with elevated longitudinal ridges open at top; cavity funnel shaped, hexagonal; height an inch, diameter at the base about three inches. Diadema.

Brit. Shells, tab. 56. fig. 1. 2, *Lepas Diadema.*

Found in whales, which occasionally visit the British shores.

SECT. II. PEDUNCULATED.

The shells of this Section are furnished at their base with a cartilaginous flexible tube, by which they are immoveably fixed. These tubes are capable of being

Multivalves.

elongated or contracted at the will of the animal. The section contains at present only one genus.

LII. Lepas.

Genus LII. Lepas.

Shell wedge-shaped, composed of several unequal valves, five or more, united at the base to a cartilaginous tube.

A. Shell composed of five pieces.

Anatifera, 1. *Anatifera.* Shell compressed, the two lower valves large and subtriangular, longitudinally wrinkled and obsoletely striated in a radiated manner from the lower anterior angle; the two superior valves long and tapering downwards to an obtuse point; the upper part angulated on each side, top rounded; dorsal valve long, slender, and rounded; length an inch and a half; pedicle and connecting ligaments reddish.

Brit. Zool. tab. 39. fig. 9.
Brit. Shells, tab. 7.

Found adhering to floating wood. This was the shell which, in the ages of superstition and ignorance, was supposed to produce the Bernacle goose.

Anserifera, 2. *Anserifera.* Shell compressed, tumid at the base, larger valves striated from the lower anterior margin; the smaller valves striated from the upper posterior margin; dorsal valve compressed, slender, and brought to a fine carinated edge; length an inch.

Brit. Shells, tab. 166. fig. 2.

Found adhering to floating wood.

Sulcata, 3. *Sulcata.* Shell compressed sub-triangular; inferior valves wrought with fifteen strong diverging ribs from the lower anterior angle; the front rib forms a margin; the two superior valves form a pointed apex, become narrow downwards to a point, and are furnished with seven or eight ribs, with smaller intermediate ones; dorsal valve compressed, strongly striated longitudinally, with a smooth subcarinated edge; length about a quarter of an inch.

Test. Brit. tab. 1. fig. 6.

Found by Mr Montagu on the Dorset coast, adhering to Gorgonia flabellum.

Fascicularis, 4. *Fascicularis.* Shell bluish-white, glossy; large valves obtusely triangular, concentrically wrinkled, and divergingly striated from the exterior angle at the base, which is dilated; upper valves wrinkled parallel with the inner margin; dorsal valve narrow at the top, increasing to about two-thirds of its length, where it is bent suddenly inwards at the base, which is dilated; apex reflected; connecting ligaments transparent; peduncle short, thin, pellucid, smooth, and of a dusky colour when the animal is alive.

Ellis's *Zoophytes,* tab. 15. fig. 6.

First described by Ellis; afterwards found by Mr Bryer at Weymouth, and by Mr Montagu on the coast of Devon. We have found it in Zetland. It is usually found in clusters, attached to a white gelatinous spherical substance, which surrounds the stalks of Fuci, and even dead feathers and floating wood. The Lepas dilata of *Brit. Shells,* tab. 164, is essentially distinct from the shell we are now speaking of, although it has been hastily concluded to be the same.

Membranacea, 5. *Membranacea.* Shell with the valves connected by broad membranes, and furnished with a short peduncle; superior valves linear, projecting, and bent downwards; inferior valves narrow, and bent backwards; dorsal valve slender, about one-third of the length of the shell; length about half an inch.

Test. Brit. page 164. *Sup.*

Said to have been found on the Welch coast.

B. Valves Numerous.

Scalpellum, 6. *Scalpellum.* Shell with thirteen valves of a light brown colour, a little rough, without striæ, faintly wrinkled in some parts, and covered with short hairs; peduncle large, cylindric, annulated; length five eighths of an inch.

Test. Brit. tab. 1. fig. 3.
Brit. Shells, tab. 166. fig. 1.

First observed as British by Mr Boys of Sandwich; and afterwards by Mr Montagu from Plymouth.

Polliceps. 7. *Polliceps.* Shell of numerous valves, five of which are larger than the rest; smooth and glossy; anterior valve on each side ovate and convex; dorsal valve subovate, thick, convex, and rounded; peduncle long, with imbricated scales; length about two inches including the footstalk.

Test. Brit. tab. 28. fig. 5.

Found by Mr Laskey on the shores of Iona.

SECT. III. IMBRICATED.

Imbricated. The imbricated shells are all included in one genus. They bear a near resemblance to one another in form and habit.

Genus LIII. Chiton.

LIII. Chiton.

Shell oblong, elliptical, convex, constructed of many plates placed transversely on the back of the animal, and lying upon one another at the anterior edge.

Marginatus, 1. *Marginatus.* Shell oblong-ovate, dusky, with eight valves projecting over each other in a point or beak, at the dorsal elevation; valves like shagreen; border rough, with a ciliated edge; length five eighths of an inch, breadth three eighths.

Lin. Trans. vol. viii. tab. 1. fig. 2.

Frequent upon stones covered with sea-weed about low water. One variety occurs with seven valves, and we have found another with only six valves.

Lævis, 2. *Lævis.* Shell oblong, reddish, marbled, with eight valves, elevated in the middle and minutely shagreened; the middle valves divided on each side into two compartments from the anterior base to the beak, the anterior division striated transversely, the posterior division striated longitudinally; border broad, striated transversely and diagonally, resembling fine hair-cloth; length rarely half an inch, breadth about a quarter.

Brit. Zool. tab. 36. fig. 3.

This is a rare shell. It was first noticed by Pennant at Loch Broom in Ross-shire; Mr Montagu afterwards found it in Salcomb-bay, Devonshire; Mr Laskey met with it at Dunbar, and we have taken it in Zetland. It inhabits deeper water than the preceding species.

Ruber, 3. *Ruber.* Shell oblong, elevated on the back, reddish, variegated, with eight valves, divided on each side, from the anterior margin to the beak, into two compartments, the anterior transversely striated, the striæ bending and crossing the posterior compartment; spaces between the stria broad; border rough; size of the last.

Lin. Syst. Nat. 1107. 7.

Common in Scotland on rocks at low water.

Cinereus. 4. *Cinereus.* Shell oblong, ovate, rounded on the back; greyish, with dusky stripes; valves eight, narrow; anterior compartment striated longitudinally, the posterior diagonally; the striæ are rough, so that the shell is shagreened; border narrow, rough; length nearly half an inch, breadth upwards of a quarter.

Multivalves.

Lin. Trans. vol. viii. tab. 1. fig. 3.

Found with the preceding species. Not common.

Albus,

5. *Albus.* Shell oblong, white, with eight valves a little pointed at the dorsal elevation; minutely shagreened; striated longitudinally at the sides, and obsoletely transversely in the middle; anterior valve large; border finely but distinctly shagreened; length a quarter of an inch; breadth one eighth.

Lin. Trans. vol. viii. tab. 1, fig. 4.

Found by Dr Pulteney at Poole in Dorsetshire. We have taken it in Zetland, adhering to stones from deep water. The Linnæan character, *valvula prima postice emarginata*, does not occur in our specimens.

Lævigatus,

6. *Lævigatus.* Shell with eight valves, elevated on the back, oblong, reddish, with white stripes; valves regularly shagreened; anterior compartment striated transversely; border smooth, scarcely ciliated; length four tenths; breadth two tenths.

A new species found in Zetland along with Chiton albus.

Fascicularis,

7. *Fascicularis.* Shell oblong, ovate; valves eight; striated longitudinally on the back, and roughly shagreened on the sides; border rough, surrounded with tufts of white hairs, one at the junction of each valve, six on the margin at the front, and two at the posterior end, making twenty in number; length five eighths of an inch; breadth above two eighths.

Test. Brit. tab. 27. fig. 5.

Lin. Trans. vol. viii. tab. 1, fig. 1.

Found in several places in England. It occurs likewise in the Frith of Forth, and in Zetland.

Crinitus.

8. *Crinitus.* Shell with seven valves, thick set with short hairs. Length five eighths of an inch.

Brit. Zool. tab. 36, fig. 1.

Inhabits the sea near Aberdeen, according to Mr Pennant. Mr Boys is said to have found it at Sandwich. It is a species involved in much obscurity.

The Sabellæ are usually described along with shells in systems of Conchology. They possess cases which are composed of sand or small shells agglutinated together, and hence do not resemble the true Testacea, whose shells are secreted from the body of the inhabitant. For a description of the different species of Sabellæ, see the article Mollusca.

Tabular view of the genera and species.

Having thus given a short description of the shells of Britain, we shall now exhibit a tabular view of the genera and species which have been mentioned, and conclude with a few directions to the young conchologist, for collecting and preserving shells.

Formation of a collection of shells.

The formation of a collection of shells, is absolutely necessary to the successful prosecution of the science of Conchology. To accomplish this, much care and attention are requisite. Shells must be sought for in their natural situations, and obtained, if possible, with the animal alive. After the animal has remained dead in the shell for any length of time, it loses its lustre and transparency, and becomes less valuable, either as an object of beauty or curiosity. Hence the collector must explore the sea-coast, the land, and the fresh water, in search of the testaceous animals which they support, for the purpose of obtaining in a perfect state their calcareous coverings.

The sea contains more species of shells than either the land or the fresh waters, and presents to the conchologist an extensive field for observation. Many species of marine shells frequent the sea shore, adhere to rocks, stones, and sea-weed, or lodge in the clay or sand. These are termed *Littoral* shells, and are seldom found in deep water. The littoral shells are easily collected at ebb tide. Those which burrow in the mud or sand, may be detected by a small depression which they leave on the surface, as they retire below it. Other shells live in deeper water. To collect these, the dredge must be employed; and if the shells be put into sea water after they are brought up, the animals may afterwards be examined with ease. Such collectors as have not the advantage of a dredge, should examine the refuse of fishing boats, and traverse the sea shore, and search the rejectamenta especially after a storm of wind. The roots of the larger *Fuci*, especially F. digitatus which grows sometimes in four or five fathoms water, frequently contain a treasure of the rarer shells.

When vessels which have been long at sea come into dock to be cleaned, their bottoms are often covered

Formation of a collection of shells.

with shells, and with sea-weed, containing numerous rare vermes. To such situations the conchologist should resort; and in these he will often be successful in finding the objects of his pursuit. In illustration of this remark, we may mention the circumstance of the vessel employed at the Bell Rock as a floating light, having had her bottom covered with mussels three inches and a half in length, and upwards of one inch in breadth, although she had only been afloat three years and seven months. She was moored the 11th July 1807, and removed the 11th Feb. 1811. Previous to being moored, she was completely caulked and pitched. The sand on the shore likewise yields many of the smaller species of shells, and should be carefully examined with the microscope.

When sea shells are obtained, they should be plunged into boiling water, to facilitate the extraction of the animal, and afterwards soaked in it for some time to remove the salt. They should then be cleaned with a brush, and all extraneous matter removed. When the shells are not soaked in water, the salt soon attracts moisture, which speedily destroys the ligaments and epidermis.

The land shells are more within the reach of the scientific collector. To obtain these, he has only to examine the crevices of rocks, the trunks of trees, decayed wood, moss, and brushwood. In summer, after a shower, the land shells are most easily procured. The animals come forth to feed on the moistened blade, and at that time, from their motion, may be very readily perceived.

The land shells are very easily preserved. Almost all that is required is the extraction of the animal.

The fresh water shells, though less difficult to procure than the sea shells, require more trouble than the land shells. A piece of gauze spread over a ring attached to the end of a staff, forms a very convenient net for fishing fresh water shells. By means of this net in the drought of summer, almost all the different species of fresh water shells may be obtained with ease.

Distribution of shells in a cabinet.

The fresh water shells are frequently covered over with slime or mud, which must be removed by a brush; and the animal may be extracted after the shell has been plunged in boiling water.

The mode of distribution of shells in a cabinet, must depend on the views of the collector. The method of keeping them is more obvious. The Bivalves and Multivalves should be disposed of in a similar manner. Each species should be placed in a box or paper case, by itself, with a label containing its name, habitat, and locality. The Univalves may also be kept in the same way. They may likewise be pasted on slips of card, each species separately, with the necessary remarks on the back of the card; or, when small, they may be stuck upon a narrow slip of pasteboard, through which a pin passes, and stuck in drawers or boxes lined with cork, in a way similar to that employed by entomologists for preserving insects.

If it is wished to have a few of the specimens of shells polished, the following methods may be employed for the purpose. If shells have naturally a dull polish, this may be heightened, by rubbing hard with the hand, or a bit of leather. When shells are rough, they may be rubbed smooth with pumice stone, and afterwards polished with crocus or tripoli; or the roughness, especially the epidermis, may be in part removed by weak acids. Where shew is the object, these polished specimens may be much admired; but where a correct taste prevails, the rough unpolished surface will be more highly prized.

Plates CCIII. CCIV. CCV. CCVI.

For an account of the structure and constitution of testaceous bodies, we refer our readers to the article Shells; and in Plates CCIII. CCIV. CCV. CCVI. he will find figures of a few of the more remarkable species which we have described. (J. F.)

Concinnous, Concords.

CONCINNOUS Intervals, in Music, are such as are apt and useful in composition or harmony, as the VIII, V, 4th, VI, III, 3rd, and 6th; and the II, VII, 7th, 2d, and IV. or 5th; in contradistinction to the Inconcinnous, or *comma-redundant*, or *comma-deficient* Intervals of these names, as VIII', V', 4', &c. or VIII`, V`, 4`, &c. The term concinnous is also sometimes used in describing musical performances or concerts, to express a very nice or perfect execution of what the composer intended; in which, not merely a mechanical exactness is given to the performance of every passage, but where the several performers enter into the very design and sentiment of the composer, and where the whole orchestra move, as though one soul inspired the whole. (ρ)

CONCORDS, in Music, or *Consonant Intervals*, are such as have a pleasing effect on the ear, whether their limiting notes are heard in succession or melody, or are sounded together in consonance or harmony. A knowledge of the true principles, on which this peculiar property, of certain consonances or intervals, called concords, depend, by which they affect the ears of all persons (though in different degrees,) with delight and pleasure, while the greater part of the other musical intervals have a contrary effect, or excite a grating and rather disagreeable sensation on the ear, and are called *discords*, remains yet among the *desiderata* in this science; we have said the greater part of the other musical intervals rank as discords, because, for reasons that seem still more difficult to discover, all the concords admit of a slight deviation, either as to excess or defect, without becoming actually disagreeable, nor indeed do their peculiar characters seem to be much altered, except by the obtrusion of a periodical noise, or audible phenomena, called a *beat*, or beatings, very different from a musical sound, that accompanies the hearing of all such imperfect or *tempered concords*; and such beats vary in their frequency of occurrence, and disagreeable effect, with (though not *proportionate to*) the degree of imperfection in such imperfect concords. See our article Beats.

Concords.

This phenomenon, of slow and audible beats, which accompanies the concords, when slightly altered from their true ratios or perfection, has been proposed by some, as a character of concord; but as this requires the same test, viz. an appeal to the sense of hearing or the judgment of the ear, to discover its existence, as it does to discover their pleasing effect, it fails of that general characteristic, or inherent property, which ought to discover itself in the ratios or other methods of expressing musical intervals, that have not actually been heard;

and discover beforehand whether they would prove concords or discords.

The concurrent experience of all musicians, and of others who have experimented on musical sounds and consonances, is, that the following intervals are concords, viz.

I	2 S+𝔖	3rd	𝒮	III	S	4th	S+𝔖	V	S	6th	𝒮	VI	2S+𝔖
$\frac{1}{1}$		$\frac{5}{6}$		$\frac{4}{5}$		$\frac{3}{4}$		$\frac{2}{3}$		$\frac{5}{8}$		$\frac{3}{5}$	

VIII	10th	x	11th	xii	13th	xiii	XV	17th	xvii	18th

xix	20th	xx	XXII	24th	xxiv	25th	xxvi	27th	xxvii
$\frac{1}{6}$	$\frac{5}{32}$	$\frac{3}{20}$	$\frac{1}{8}$	$\frac{5}{48}$	$\frac{1}{10}$	$\frac{3}{32}$	$\frac{1}{12}$	$\frac{5}{64}$	$\frac{3}{40}$

XXIX	31st	xxxi	32d	xxxiii	34th	xxxiv	XXXVI
$\frac{1}{16}$	$\frac{5}{96}$	$\frac{1}{20}$	$\frac{3}{64}$	$\frac{1}{24}$	$\frac{5}{128}$	$\frac{3}{80}$	$\frac{1}{32}$

38th	xxxviii	39th	xl	41st	xli	XLIII	45th	xlv	46th
$\frac{5}{192}$	$\frac{1}{40}$	$\frac{3}{128}$	$\frac{1}{48}$	$\frac{5}{256}$	$\frac{3}{160}$	$\frac{1}{64}$	$\frac{5}{384}$	$\frac{1}{80}$	$\frac{3}{256}$

xlvii	48th	xlviii	L, &c.
$\frac{1}{96}$	$\frac{5}{512}$	$\frac{3}{320}$	$\frac{1}{128}$, &c.

and that all the amazing variety of other intervals (except those *near* to any of these concords, as above mentioned) within these seven octaves, are *discords*.

Wherein it is observable, in comparing the terms of the ratios of all these concords in the lowest line, belonging to the intervals major and minor, as expressed above them in the first line, that the numerator, or least term of the ratio, *never exceeds* 5; and that in the third and all succeeding octaves in ascending, the numerators are 1, 5, 1 3, 1, 5 3 and 1. That 4 never appears as a numerator but in the first octave, and 2 only in the two first octaves. That the denominators, or largest term of the ratios of the concords in the above seven octaves, constitute the following series, when arranged,

viz.

1,	2,	$^{2}3$,	$^{2}4$,	$^{4}5$,	$^{2}6$,	$^{3}8$,	$^{2}10$,	$^{2}12$,	$^{3}16$,	$^{2}20$,	$^{2}24$,
	1	1	1	1	1	2	2	2	4	4	4

$^{3}32$,	$^{2}40$,	$^{2}48$,	$^{3}64$,	$^{2}80$,	$^{2}96$,	$^{3}128$,	160,	192,
8	8	8	16	16	16	32	32	32

$^{2}256$,	320,	384,	and 512.
64	64	64	128

The small figures prefixed, denoting the number of times that these occur as denominators, in these seven octaves. All the numbers in the above series will be found included in one of the following three *forms*, viz. 2^x, $2^x \times 3$, or $2^x \times 5$; where $2^0 = 1$, $2^1 = 2$, $2^2 = 4$, &c. or *the powers of 2 are indefinite, while only the first power of 3 or of 5, enter into any of the largest terms of the ratios of concords.* If we examine the *differences* in the above series of numbers, it will be observed, that they are powers of 2, viz. 2^0 (or 1), 2^1, 2^2, 2^3, 2^4, 2^5, and 2^6; and that after the number 3, or third term of the series, they proceed by three of each of these, in succession; the consequence of three different forms being combined in this one series, as above.

In the middle line of the first octave, the *intervals* of the *original* concords therein, (as such are called,) are set down, viz. 2 S+𝔖, 𝒮, S, S+𝔖, S 𝒮 and 2 S+𝔖, in the Chromatic *Elements* (see that article); by which it appears, that the octave is similarly divided by the original concords, into two similar parts, but reversed; or, the progression is the very same in proceeding from both its extremities towards the middle of the first or original octave, and so of all the superior ones. It thus also appears, that where the numeral designation of the concords differ *two*, as between I and 3, and VI and VIII, the difference is S+𝔖, or the 3rd; where the same differ *one*, as between III and 4th, and V and 6th, the difference is S; and where the numerals are the same, only major and minor, as between 3d and III, and 6 and VI, the difference is 𝒮: these last have, by Dr Callcott, Dr Busby, and many other writers, most improperly and unnecessarily been called *imperfect* concords, merely because they are sometimes major and sometimes minor, and the VIII, V, and 4th *perfect*, because each of them have but one numeral designation; whereas *imperfect concords* should always mean *tempered* or altered concords, as above mentioned.

These several concords are not equally harmonious, satisfactory, or pleasing to the ear, either considered or compared altogether, or in groups, within each successive octave, respectively; but it seems agreed by Dr Robert Smith, Dr Robison, and others of the best modern writers on the subject, that their order of simplicity, or smoothness of effect on the ear, in the 1st octave, is I, VIII, V, 4th, VI, III, 3rd, and 6th; or $\frac{1}{1}$, $\frac{1}{2}$, $\frac{2}{3}$, $\frac{3}{4}$, $\frac{3}{5}$, $\frac{4}{5}$, $\frac{5}{6}$, and $\frac{5}{8}$; which ratios form series, increasing with the degree of comparative roughness or want of pleasing effect in the concord, as above, whether we contemplate the numerators, the denominators, or the *sum* of these, viz. 2, 3, 5, 7, 8, 9, 11, and 13. If we arrange all these several concords in seven octaves, according to the *sum of the terms* of their respective ratios, they will stand as follows, viz.

I	VIII	XII	V and XV	XVII	4th, X and XIX	VI
2,	3,	4,	5,	6,	7,	8
		V	VIII	III	III V	

III and XXII	3d, 11th, and XXIV	6th, XIII and XXVI
9,	11,	13,
VIII	4th III	VI V

10th and XXIX	18th	13th and XXXI	XX	XXXIII
17,	19,	21,	23,	25,
3d VIII	4th	6th III	VI	V

17th	XXXVI	25th	20th	XXXVIII	XXVII	XL
29,	33,	35,	37,	41,	43,	49,
3d	VIII	4th	6th	III	VI	V

24th	XLIII	32d	27th	XLV	XXXIV	XLVII	31st
53,	65,	67,	69,	81,	83,	97,	101,
3d	VIII	4th	6th	III	VI	V	3d

L	39th	34th	XLI	38th	46th	41st	XLVIII
129,	131,	133,	163,	197,	259,	261,	323,
VIII	4th	6th	VI	3d	4th	6th	VI

45th and	48th
389,	517
3d	6th

Where the middle line shews the sums of the terms in the concords expressed above, and the lower line the original concords, of which many of the same are compounded, by the addition of octaves. In comparing the first 16 terms of this complete series of concords, in the order of the sums of their terms, with the similar series above, when only the eight original concords in the first octave are considered; it will appear, that the XII or octave of the Vth is here interposed between the VIII and V; and the XV and XVII, or 2 VIII and VIII+III, are interposed between the V and 4th as they stood in the original concords, which superior simplicity of the doubled concords XII and XVII, to their respective originals, seems to point out one reason of these and the double octave being the only Tartinian sounds that are heard to accompany a note; since no other doubled concords but XII and XVII, have a less sum to the terms of their ratio, than their originals have. It is further observable, that X and XIX or VIII + III and 2 VIII + V, are interposed here, between the 4th and VI of the original series; that XXII or 3 VIII is interposed between III and 3d; and 11th and XXIV or VIII + 4th and 3 VIII + III between 3d and 6th.

Whatever confirmation Dr Smith's position (*Harmonics*, 2d edit. p. 21), respecting the comparative simplicity of the concords, as above, agreeing with their order as to smoothness and pleasant sensations that they excite on the ear, may receive from the preceding Tables, it must be plain, from an inspection of his general Table of the order of the simplicity of consonances, including both concords and discords, those beyond, or expressed by larger primes than 5, as well as those in the received system of music that involve no such large primes, that this is an imperfect and false rule of judging of the smoothness or harmoniousness of consonances in general, since in his table, the false tripled minor seventh of the trumpet, $\frac{1}{7}$, or 2 VIII + 7th—13.9471 Σ—*m*, occurs before the perfect VI, and the tripled major tone $\frac{2}{9}$, or 2 VIII + II, a discord, before the perfect 3d! which must be quite contrary to their comparative effects on the ear.

We should, perhaps, earlier have pointed out, from our series of the fifty concords in seven octaves, given above, that the three least, or 3rd, III, and 4th, being considered as the *simple* concords, or concordant elements, the three next largest, V, 6, and VI, are generated by adding these simple ones in pairs, in every possible way, and the next, or VIII, by adding the three together; and that every succeeding concord in the scale, is generated by adding an octave (3 + III + 4), or two octaves (2 3, 2 III, 2 4), or three octaves, &c. to each one of the seven original concords in the first octave. Whence it appears, that no concord but the octave will bear adding to itself once, or any greater number of times, (without other combinations,) without becoming a discord; but that the addition once, or any greater number of times of the octave, to any concord, will produce another concord.

That the complement, or remainder, when any one of the original concords is taken from the octave next above, or VIII, or from any of the succeeding octaves, the remainders are all concords; and so are the complements of any of the doubled, tripled, quadrupled, &c. concords in the second, third, fourth, &c. octaves, to the next, or any succeeding octave above them; and in like manner, in the second, third, fourth, fifth, &c. octaves, one or more VIII^{ths} may be taken away from any of the concords therein, and still leave remainders that are concords, &c.

Among the various attempts of philosophers to define the limits, or shew characteristic distinctions between concords and discords, generally, Mersenne and Kircher maintained, that those consonances are most simple or agreeable which are generated in the least time, or have the smallest least terms to their ratios; and those, on the contrary, the most compound and harsh, which are generated in the largest time, or have the largest least term or numerators to their ratios. This rule is shewn, however, by Malcolm, to be defective; and Dr Smith has done the same thing, and thence concludes, "that the frequency of coincidences is of itself too general a character of the simplicity or smoothness of a consonance, and therefore an imperfect one." (*Harmonics*, p. 23.) In another place, Dr Smith says, (p. 15.) that it is the "mixture of pulses succeeding one another in a given cycle of times, terminated at both ends by coincident pulses, and sufficiently repeated, which excites the sensation of a given consonance;" and "one consonance may be considered as more or less simple than another, according as the cycle of times belonging to it, is more or less simple than the cycle belonging to the other."

M. Euler says, when the ear readily discovers the relation subsisting between the terms of the ratios of two notes, their combination is denominated consonance or concord; and if it be very difficult, or even impossible, to catch this relation, the combination is termed dissonance, or discord." *Letters*, vol. i.

Mr Holder attempts, but without any success, to account for the pleasure derived from concords, or sounds in the more simple musical ratios, by the mind being occupied in parcelling out the numbers, but not by *division*, (which with primes is indeed impossible,) but by unequal and fanciful partitions of them into what he calls factors or parcels, as 5 into 2, 1, 2, 7 into 3, 1, 3, &c.; and principally on this whimsical ground, he labours to shew, that 7 ought to have place among musical ratios! &c. "No combination," says he, "ought to be esteemed *concord*, however simple and eligible its terms may be in every other respect, if the implied sound (that is, its grave harmonic) be three octaves or more below the lower term." *Essay*, p. 376. And again, "An interval which is concord in the upper parts, is often no concord when taken in the bass!" for "we lay it down as a rule, that the implied sound of a concord ought always to be within the limits of audible sound." The introduction of which last absurdities into his Essay, Mr Farey has shewn to have arisen, from Mr Holder being unacquainted with the true nature of the grave harmonics, or the rule for calculating those belonging to any assigned consonances.

Dr Robison says, "a musical sound is the sensation of a certain form of the aërial undulation which agitates the auditory organ. The perception of harmonious sound, is the sensation produced by another definite form of the agitation: This is the composition of two other agitations; but it is the compound agitation alone that affects the ear, and it is its form, or kind, which determines the sensation, making it pleasant or unpleasant, or in other words a concord or a discord." Our limits will not admit of enlarging further on this very curious and intricate subject, which presents yet a rich field for the successful cultivator of it. (ϱ)

CONCORDANT Elements, in Music. Consonant elements, or *simple* concords, are the minor and major third, and the minor fourth, 3rd, III, and 4th, or three least concords, which by addition form all other concords that are known; every combination of them, singly, by two's and by three's, being concords, &c. as shewn in the article Concord. Intervals when expressed in the notation by *concordant elements*, are capable of being tuned by means of perfect concords only, on instruments like the euharmonic organ of Mr Liston, having a sufficient number of pipes. CONDALIA, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 177.

1

CONDAMINE, Charles Maria de la, a celebrated French traveller and philosopher, was born at Paris on the 28th January 1701, and was the son of Charles de la Condamine, receiver-general of finances for the province of Bourbonnois, and of Margaret Louisa de Chources. At an early age he was sent to school, where he exhibited no marks either of industry or talents; and he was afterwards instructed in literature and philosophy at the College of Louis le Grand, under P. Porée and P. Brisson, the latter of whom, even so late as 1717, still taught the philosophy of Descartes.

After quitting college, Condamine went as a volunteer to the siege of Roses in 1719, along with his uncle the Chevalier de Chources, who was captain of the Dauphin's regiment of cavalry. In the course of this siege, Condamine displayed a degree of courage bordering on temerity; and he was on one occasion found upon an eminence, examining through a telescope one of the enemy's batteries, the balls from which were falling thick around him. This carelessness and contempt of danger, which was afterwards a predominant feature in the character of our author, he had exhibited on a very different occasion, and at an early period. When he was scarcely twelve years of age, he went on a visit to the country; and having learned, that one of the fields near the house where he lived was visited by an apparition, he requested two of the domestics to conduct him to the park. They had scarcely reached the spot, when his two attendants fled with terror at the sight of the apparition, who, clothed in white, advanced towards them. Condamine kept his position, and having drawn a sword which he had concealed under his coat, he broke it in pieces upon his spiritual opponent. "The phantom is corporeal," he cried, "and has broken my sword." The coachman instantly emerged from his white covering, and acknowledged, that the plan was laid to try the courage of Condamine.

Although Condamine was particularly qualified for a military life by his intrepidity and personal courage, yet the ardour of his mind, and his indefatigable curiosity, prompted him to abandon a profession which, in the time of peace, presented few opportunities for the gratification of his favourite views. He henceforth resolved to devote himself to the sciences; and in the year 1730, he was admitted into the Academy of Sciences as adjunct chemist, and was already well known as one of the most active members of the Society of Arts, established at Paris by the Count de Clermont.

In the year 1731, Condamine embarked on board the squadron commanded by M. du Guay-Trouin, and visited many parts of the Mediterranean, and the coasts of Africa and Asia. In his way from Jerusalem to Constantinople, Condamine stopped at Bassa, the ancient Paphos. A Greek, who had been in the same vessel with him, was taken suddenly ill, and entrusted Condamine with 50 piastres, to be given to his parents. The Cadi of the place having insisted on appropriating this money to his own use, Condamine protested that he would give it no person but to the parents of his companion, and immediately set off for his vessel. A Titafa, an officer of police, with a numerous detachment, attempted to arrest Condamine and his servant; but after having resisted their attempts for some time, they at last sought for safety in flight, and, favoured by the darkness of the evening, they escaped to a boat, and endeavoured to regain their vessel. Finding it impossible, however, to reach the ship before break of day, and being exposed to the fire of the fort and of the Turkish vessels, they were compelled to surrender, and were carried half naked before the officer of police, who again demanded the 50 piastres. Condamine persisted in refusing them, complained of the barbarous treatment he had received, and threatening the Titafa with the vengeance of the Divan, he was at last set at liberty. After remaining five months at Constantinople, he returned to Paris, and published some account of his travels in a paper read to the Academy, and entitled *Observations Mathematiques et Physiques faites dans un Voyage du Levant, en 1731 et 1732.* Another account of his travels was published in 1734, by his valet de chambre, and without the consent of Condamine.

The Academy of Sciences was now charged with the splendid undertaking of measuring a degree of the meridian and of the equator in Peru; and Condamine, who had the honour of proposing the expedition, was one of the academicians who were selected for carrying it into effect. We have already had occasion to give some account of this great enterprize; and in another part of our work our readers may expect very satisfactory and copious details; but we can only at present relate the events which are particularly connected with the personal history of Condamine, and which could not be introduced with propriety under another head.

The academicians set out from Rochelle on the 16th of May 1735, and they reached Martinique on the 22d of June. On the day fixed for their departure, Condamine was seized with a violent fever; but such was the zeal of all the party to prosecute the object of their mission, that Condamine was embarked in the course of 24 hours after he was attacked. From Martinique the academicians went to Portobello; and, crossing the isthmus of Panama, they embarked at this city, and afterwards reached Guaquil, from which it was necessary to proceed to Quito by land. In order to examine as wide an extent of country as possible, Condamine separated from his companions, and chose a dangerous and difficult route. He traversed immense forests on foot; and after being abandoned by his guides, he wandered eight days in the deserts, without any other guide but his compass, and without any other food but the wild herbs that grew around him. After undergoing incredible dangers, and suffering the greatest privations, he at last joined his companions at Quito.

The pecuniary resources of the academicians were now unfortunately exhausted. Condamine had, however, brought with him particular letters of credit; but as there was no direct intercourse between Quito and Europe, he found it necessary to undertake a journey of 400 leagues to Lima, for the purpose of obtaining money. After an absence of three months, he returned to Quito with 60,000 livres, for which he was personally responsible, and with 20,000, which were sent to him by the council and the viceroy; and although he was obliged to carry his own bed, yet he found time to compose a memoir on the tree which yields Quinquina, and to collect a number of curious observations.

The geometrical mensuration of the arc of the meridian was completed in August 1739, after two years of unremitting labour; and the academicians were proceeding to take the astronomical measure of this arch, Condamine. when their attention was called to a most distressing event. M. Seniergues, who accompanied the expedition as surgeon, had a personal quarrel with the Alcade of Cuenca, who had interested the Grand Vicar of Cuenca in his quarrel. At a bull-fight, in August 1739, where a number of people were collected, the Spanish officers instigated the populous to the assassination of Seniergues; and, notwithstanding the great exertions of Condamine to bring them to justice, and the partial success which he at last obtained, the culprits continued to evade the sentence of the law, by means which could succeed only under the most corrupt and infamous governments.

While M. Godin was making observations on the meridian to the north, M. Bouguer repeated in the south the observations which he had formerly made, and detected an error, to the amount of 30″, which he had committed, with the cause by which it had been produced. This circumstance gave rise to a difference between Bouguer and Condamine, the former of whom maintained, that the method of detecting and providing against the error of 30″ belonged to himself alone. Condamine maintained, that Bouguer had no title to appropriate this honour to himself; and therefore carefully repeated all the second observations of his companion. In these labours they were engaged till 1743.

On the 4th of September 1742, Condamine set out from Quito. A few days before his departure, he had been robbed of his papers, the result of eight years of incessant labour; but though his money and jewels were also carried off, he had the prudence to publish a notice, declaring that he demanded only his manuscripts. This notice had the desired effect. The papers were restored, with the exception of two packets, which contained an account of his travels to the mountains where gold mines were supposed to exist.

M. Condamine left Peru on the 11th of May 1743, and he came to the hazardous resolution of returning home by the river Amazons, attended by a single domestic. After a series of dangers, for an account of which we must refer to his own work,* he arrived at Cayenne, and waited more than five months for a vessel to carry him to France. This delay preyed so much upon his mind, that it began to produce a serious impression upon his health, just when the governor of Surinam announced to him an opportunity of returning to Europe. He landed at Amsterdam, and soon found himself among his friends at Paris.

The jealousy between Bouguer and Condamine, which had already shewn itself in Peru, was again roused upon the arrival of the latter. The interest which he excited among the gay circles of Paris by the singularity of his travels, by the personal courage which had uniformly sustained him, and by his great powers of conversation, made his company very generally courted, while the mighty pretensions of Bouguer were in a great measure overlooked. To a person acquainted with human character, this unequal distribution of praise would have occasioned no uneasiness; but Bouguer possessed little knowledge of the world, and he ceased to support the dignity of his character when he repined at the admiration which was lavished upon his friend. Every person was capable of estimating the talents, and of being instructed by the conversation of an active and eloquent traveller like Condamine, while it is Condamine. the lot of few to appreciate the immortal labours by which Bouguer has enriched the sciences. The dazzling recompence of specious talents and superficial acquirements perishes with the gay crowds by whom it is conferred; but it is the splendid destiny of genius, that its rewards and its labours are alike eternal. The one is like the gaudy arch which vanishes with the shower that gives it birth; the other like the circle of the galaxy which keeps its place in the firmament, and shines with a sober but unextinguishable light.

When the quarrel between the two academicians was brought to a close, Condamine devoted his attention to the subject of an universal measure. He proposed to employ as an unit the length of a pendulum vibrating seconds under the equator, a plan which was afterwards adopted at the Revolution.

In the year 1754, Condamine became a keen supporter of the system of inoculation for the small pox, which had already been extensively practised in England and Holland. He published a Memoir on the subject, in the Memoirs of the Academy, and also a collection of papers upon the same subject.

In the year 1757, he undertook a journey to Italy for the benefit of his health, and upon his return to Paris he read to the Academy a paper entitled *Extrait d'un Journal de Voyage en Italie*, which contained much curious information. Having employed himself when at Rome in fixing the dimensions of the principal Roman edifices, he was then led to an examination of the ancient measures of length, which he endeavoursd to determine on the hypothesis, that every leading part of an ancient building would contain a round number of the given measure. His attention was also directed to the geognostic structure of Italy, and he examined with care the remains of its extinct, volcanoes, and the interesting phenomena exhibited by Vesuvius. In the course of his journey he obtained a dispensation to marry his own niece, a connection which tended greatly to promote his future happiness.

He was received a member of the Academy of Inscriptions and Belles Lettres in 1760, and he contributed greatly to the last edition of the Dictionary. On this occasion he published Letters on Dictionaries and on Education.

In 1763 Condamine went to England. He had been elected a Fellow of the Royal Society so early as the 15th December 1748, and he was now admitted on the 12th of May 1763.

Soon after his return from England, Condamine was attacked with a great insensibility in his extremities. He was now unfit for any laborious occupation, and he occasionally amused himself in the composition of poetry. Several of his tales in verse were published in the periodical journals, and likewise a translation of part of the Æneid of Virgil. In addition to the paralysis of his extremities, he was attacked with hernia, and he was unfortunately prevailed upon by an empiric, to attempt its cure by the application of caustics. He died, however, of the effect of the operation, 45 days after it was performed, on the 4th of February 1774, in the 73d year of his age.

M. Condamine was Knight of the Royal Military Order of Notre Dame and Mount Carmel, and of St Lazarus at Jerusalem. He was elected a member of

* *Relation abregée d'un Voyage dans l'Interieur de l'Amerique Meridionale, depuis la cote de la Mer du Sud, jusqu'aux cotes du Bresil, et de la Guyane, en descendant la Riviere des Amazones.*

the academies of Petersburgh, Berlin, Bologna, Cortona, and Nancy, and he was honorary secretary to the Duke of Orleans.

The personal appearance of Condamine was by no means interesting. His face was greatly disfigured by the ravages of the small-pox, but his vivacity and fluency in conversation amply compensated for this defect in his bodily appearance. Condamine does not seem to have possessed any of that inventive genius which enriches and extends the sciences by great and original views. Though he acquired a general knowledge of all the sciences, yet he did not attach himself with sufficient attention to any of them. The activity and ardour of his mind were constantly hurrying him into labours which required the exercise of those great qualities. His mind was of a texture too chivalrous for the peaceful pursuits of science; and we are strongly impressed with the opinion, that he forsook his own destiny when he exchanged the sword for the level and the plumb-line. In estimating therefore the claims of Condamine upon posterity, we cannot deny him the praise of possessing a bold, active, and intrepid mind, which was constantly exerting itself for some great and important object, and which surmounted every danger and difficulty that obstructed its accomplishment. His knowledge was extensive, and in some cases profound; and as a writer, his style was easy, simple, and elegant. But he can lay no claim to those higher qualities of the mind which can alone conduct the philosopher into the Elysium of invention and discovery.

The following is a correct list of his papers, which are published in the Memoirs of the Academy of Sciences.

Observations sur une nouvelle manière de considerer les sections coniques, 1731, p. 240.

Observation sur une nouvelle espèce de végétation métallique, 1731, p. 466, H. 31.

Observations mathématiques et physiques, faites dans un voyage du Levant en 1731 et 1732. 1732, p. 295.

Description d'un instrument qui peut servir à déterminer sur la surface de la terre, tous les points d'un cercle parallèle à l'équateur, 1733, p. 294. H. 53.

Nouvelle manière d'observer en mer la declinaison de l'aiguille aimantée, 1733, p. 446.

Recherches sur le tour, Premier mémoire, 1734, p. 216.

Second mémoire, 1734. p. 295.

Addition ou mémoire qui a pour titre: Nouvelle Maniere d'observer en mer la declinaison de l'aiguille aimantée; extrait d'une lettre de M. De La Condamine, de Saint Domingue, le 15 Juillet 1735, 1734 p. 597.

Manière de déterminer astronomiquement la différence en longitude de deux lieux peu éloignés l'un de l'autre, 1735. p. 1.

De la mesure du pendule à Saint Domingue, 1735. p 529.

Observations sur l'arbre du Quinquina, 1738. p. 226.

Relation abrégée d'un voyage fait dans l'intérieur de l'Amerique méridionale, depuis la côte de la mer du Sud, jusqu'aux côtes du Brésil et de la Guane, en descendant la rivière des Amazones, 1745, p 391. H. 63.

Extraits des operations trigonométriques, et des observations astronomiques, faites pour la mesure des degrés du méridien aux environs de l'équateur, 1746. p. 618.

Nouveau projet d'une mesure invariable, propre à servir de mesure commune à toutes les nations, 1747, p. 489. H. 82.

Mémoires sur une résine élastique, nouvellement découverte à Cayenne, par M. Fresneau; et sur l'usage de divers sucs laiteux d'arbres de la Guiane, ou France équinoxiale, 1751. p. 319. H. 17.

Memoires sur l'inoculation de la petit vérole, 1754. p. 615.

Extrait d'un Journal de voyage en Italie, 1757. p. 336. H. 6.

Second mémoire sur l'inoculation de la petite vérole contenant la suite de l'histoire de cette méthode et de ses progrés de 1754, à 1758, 1758. p. 439.

Observâtions sur l'amiante très-blanche, trouvée dans les montagnes de la Tarentaire, 1761, H. 31.

Suite de l'histoire de l'inoculation de la petite vérole, depuis 1758, jusqu'en 1765. Troisième memoire, 1765. p. 505.

Observations de M. Spallanzani, sur des limaçons à qui on avoit coupé la tete, auxquels il en a poussé une nouvelle, 1768, H. 34.

Machine pour exécuter sur le tour toutes sortes de contours réguliers et irreguliers, Mac. T. 5. p. 83.

Machine pour tailler toutes sortes de Rosettes. Mac. T. 5. p. 89. (*o*)

CONDENSATION. See EXPANSION.

CONDENSER. See ELECTRICITY and PNEUMATICS.

CONDENSER OF FORCES, is the name of a contrivance invented by M. Prony for obtaining from a first mover the greatest possible effect. See MECHANICS.

CONDILLAC, STEPHEN BONNET DE, a celebrated French metaphysician, whose writings throw around his name a distinguished lustre, while his private history is involved in singular obscurity. He first became known to the world as an author in 1746, when he published his "*Essay on the Origin of Human Knowledge.*" His object in this work is to develope the faculties of the human mind, by tracing historically the progress of its operations. In his next work, entitled, "*A Treatise on Sensations,*" he endeavours to account for the origin of memory, judgment, and the mental affections, and the gradual formation and correction of sensible ideas, by imagining to himself a statue, provided at first with a single sense, and with the others in succession. The fame of his writings had procured him the honourable situation of preceptor to Don Ferdinand, Prince of Parma, for whose instruction he drew up a "*A Course of Study,*" &c. which he afterwards published in 16 duodecimo volumes. In the introduction to these volumes, he enters into a discussion of the comparative advantages of the different modes of instruction, judiciously giving a decided preference to the mode of advancing gradually from particular facts up to general principles. Logic, metaphysics, and the philosophy of the human mind, are comprehended among the earlier stages of this course of study; from which he proceeds to the study of history, of which he has given an ample and well-arranged abridgment, in eleven volumes. Condillac likewise published a "*Treatise on Animals,*" in which he endeavours to refute the notions of Descartes and Buffon, concerning the mechanical nature of brutes, and to shew in what manner their faculties are derived; and a small work, entitled, "*Commerce and Government considered relatively to each other.*" He died in 1780, leaving behind him a splendid reputation, deservedly acquired by the extent of his knowledge, the soundness of his judgment, and the clear and comprehensive views which he took of every subject towards which his mind was directed. (*k*)

Condorcet. **CONDORCET, Jean Antoine Nicolas de Caritat, Marquis de**, a celebrated mathematician and philosopher, was descended of an ancient and noble family, and was born at Ribemont in Picardy, on the 17th of September 1743. He received his education at the College of Navarre, where he was distinguished among his fellow students for his ardour in the acquisition of knowledge, and for his extreme partiality to mathematical and physical pursuits. In the year 1765, when he was in the 22d year of his age, he published his *Traité du Calcul Integral*, in which he proposed to give a general method of determining the finite integral of a given differential equation, either for differences infinitely small, or for finite differences. This work, which is noticed in the History of the Academy for 1765, (p. 54.) had the honour of being praised by D'Alembert and Bossut, who were employed by the Academy to examine it. They stated that the greater part of the methods were invented by Condorcet; that it exhibited a degree of knowledge rarely to be met with at so early an age; and that it afforded a presage of talents which the approbation of the Academy could not fail to excite. This work was followed by his *Essais d'Analyse*, in four parts, the first of which was published in 1765, the second in 1767, and the third in 1768. This work relates principally to the system of the world, and to the solution of the problem of three bodies; but these subjects, as La Lande has already remarked, are treated with a generality which is insufficient for astronomy. On the 8th March, 1769, he was admitted into the Academy of Sciences as joint mechanician, and as associate on the 22d December 1770; and in this situation he formed a friendship with D'Alembert which lasted during his life. He was appointed, along with D'Alembert and Bossut, to assist the celebrated Turgot in his financial calculations; and about the same time he wrote, under the title of *Lettres du Laboureur*, a reply to Necker's essay on the corn laws, entitled *De la Legislation et du Commerce des Grains*, and he published an anonymous defence of the political sect to which he had attached himself. This last work was entitled *Lettres d'un Theologien à sons fils*, and was intended as an answer to the Abbe Sabbatier's *Dictionnaire des Trois siecles de notre Literature*. It contains a great deal of unmanly and illiberal abuse, directed against religion and its ministers; and, as if even this was not a sufficient display of his opinions, he afterwards published his *Commentaire des Pensées de Pascal*, which is filled with the principles of the most determined atheism.

In 1773 he published, at Paris, the *Eloges des Academiciêns de l'Academie Royale des Sciences mort depuis* 1666 *jusqu'en* 1699. This work contains the lives of Huygens, Picard, and Roemer, who were not included in the Eloges either of Fontenelle or D'Alembert, and, if we believe La Lande, was written at a time when he was ambitious of the secretaryship to the Academy of Sciences, and with the view of shewing that he was qualified for that important office. Influenced probably by the genius displayed in these eloges, as well as by the high opinion entertained of him by D'Alembert, the Academy appointed him adjunct secretary, with the reversion of that office, on the 10th of March 1773.

A vacancy having occurred in the French Academy by the death of M. Saurin, in 1782, Condorcet was proposed as a candidate by his friend D'Alembert, while M. Bailly, the celebrated author of the *History of Astronomy*, was supported with all the influence of the Count de Buffon. Bailly had been vanquished, at the last election, by M. Chamfort, by only three or four votes, and was therefore supposed to have the best chance of succeeding Saurin. D'Alembert, however, employed all his address and activity in the cause of his friend, and he at last succeeded in securing Condorcet's election by the single vote of M. de Tressan, at a meeting consisting of 31 members. This academician, who owed his place in the Academy to Buffon, had promised his vote both to Bailly and Condorcet, but D'Alembert, who was more acquainted with human character than Buffon, had the precaution of obtaining a written promise from M. de Tressan, and of thus securing a vote which might otherwise have decided the election of Bailly. The discourse which Condorcet delivered to the Academy at his admission, does not appear to have answered the high expectations of his friends. It related principally to the rapid progress of knowledge during the 16th century, and to the doctrine of the infinite perfectibility of the human mind, an opinion which seems to have decayed with the revolutionary spirit in which it had its origin, and which could be maintained only by men who were intoxicated with a false and extravagant estimate of their own powers.

In the year 1778, when the Academy of Sciences at Berlin proposed a prize for the best dissertation on the theory of comets, Condorcet transmitted an essay, which was however unsuccessful. It was published along with one of Tempelhoff's and two of Hennert's prize dissertations, in a quarto volume, entitled *Dissertations sur la Theorie des Cometes*. Utrecht, 1780.

Upon the death of D'Alembert in 1783, Condorcet succeeded, in virtue of his former appointment, to the Secretaryship of the Academy of Sciences, and in this office he distinguished himself by his Eloges on some of the most celebrated members. His Account of the Life and Discoveries of D'Alembert and Euler; his Eloge on the celebrated Turgot; his Life of Voltaire, which appeared in 1787; and his Biographical Account of Dr Franklin, which appeared in 1790, display a deep knowledge of science and of character, and exhibit the peculiar talent which Condorcet eminently possessed, of giving a perspicuous and comprehensive view of the labours and discoveries of others.

Amidst the duties of his new office, Condorcet did not forget his mathematical pursuits. His attention was turned particularly to the doctrine of chances; and he treated this subject in a series of four memoirs, entitled, *Sur le Calcul des Probabilites*, and printed in the Memoirs of the Academy between 1781 and 1785. He published also a separate work on the subject, entitled, *Essai sur l'application d'analyse à la Probabilité des Decisions*, 4to, 1785. In the application of the results of his investigations to the practical purposes of life, he examined the probability of an assembly's giving a true decision, and he explained the limits to which our knowledge of future events might extend, when regulated by the laws of nature. He supposed that we have, at least, a mean probability that the law indicated by events is constant, and will be perpetually observed. He regarded a forty-five thousandth part as the value of the risk, in the case when the consideration of a new law comes under our notice; and it results from his formulæ, that an assembly consisting of 61 voters, where it is requisite that there should be a plurality of nine, will fulfil this condition, if there is a probability that each vote is equal to five-fifths, that is, if there is a probability that each member shall be deceived only once in five times. These calculations he next applies to

Condorcet. the establishment of tribunals, to the forms of elections, and to the decision of numerous assemblies.

Condorcet was at this time employed, in conjunction with M. Sejour, and M. de la Place, in estimating the population of France; and the results of their labours were successively laid before the public in six memoirs, which were published in the Memoirs of the Academy, between the years 1784 and 1788.

About this time Condorcet had suggested the idea of a dictionary, in which objects are to be found by their properties, instead of by their respective names; and he at the same time gave notice of a scheme for constructing Tables, by means of which ten milliards of objects might be classed together by only ten different modifications.

Condorcet took an active part in the various political events which preceded and accompanied the French revolution, and his numerous writings on philosophical and political subjects are supposed to have accelerated that awful event. He conducted a work entitled *La Bibliotheque de l'Homme Public*, containing analyses of the works of the most eminent political writers; and a newspaper called *La Chronique de Paris*, which was filled with the most petulant declamation against royalty.

When the king of France fled to Varennes, Condorcet united himself with Brissot and Thomas Paine, two of the most determined republicans, and none of whom were members of the constituent assembly; and they commenced a periodical paper, called *Republicain, ou le Defenseur du Gouvernment Representatif*, which was filled with the most detestable principles. The papers written by Thomas Paine were translated by the Marchioness de Condorcet; but Condorcet was the principal contributor to this disgraceful publication. In one of the papers which he published in the *Republicain* Condorcet attempts to refute the argument in favour f a monarchical government, that a legal king is the best security against a tyrant, since a power limited by the constitution is less formidable than the undefined power of an ambitious usurper; and after adducing a variety of arguments to prove, that there is now less danger of usurpation than there was in the days of Sylla, Cæsar, Guise, and Cromwell, he maintains, that, in future, the art of printing, the liberty of the press, and the free communication of knowledge by means of newspapers, will *infallibly* preserve the human race from similar usurpations.* Condorcet lived long enough to see this contemptible reasoning completely refuted by the usurpation of Robespierre; and those who survived him have witnessed another refutation of it still more triumphant. It is thus that the great events of life are constantly putting to shame the speculations of that school of philosophy, which, ignorant of the true character and destiny of man, represents him as hastening to a state of perfection of which his nature is unsusceptible.

Condorcet was a staunch member of the Jacobin club, and he spoke frequently at its meetings. He was elected one of the representatives for Paris, at the dissolution of the Constituent Assembly; and his political views accorded, in general, with those of the Brissotine faction. He was called upon to digest a plan of public instruction, which he completed in two memoirs, replete with exalted and enlarged sentiments, though tinged with the peculiar views of their author. Condorcet. He was selected as the most fit person to draw up the manifesto which was addressed by the people of France to the powers of Europe at the commencement of the war; and he wrote a letter of expostulation to the king, as president of the assembly, which was marked by an unnecessary and an unceremonious severity. Condorcet is said to have vindicated the proceedings of the mob when they insulted the king at the Thuilleries; and when he was thus forgetful of his duty as a subject, he is reported to have been secretly soliciting the situation of tutor to the dauphin, which, on account of his open infidelity, the king refused to confer upon him. The enemies of Condorcet have accused him of being accessory to the murder of the Duke de la Rochefoucault, who was the near relation of his wife, and to whom he owed the most substantial obligations; but it is difficult to discover, from the total want of information on the subject, whether he was innocent or guilty of this heinous crime.

When the trial of Louis XVI. was the subject of discussion, Condorcet maintained that he could not legally be brought to judgment; yet, when sentence of death was pronounced upon him, he had not the courage either to defend or avow his former sentiments.

After the death of the king, the Gironde party employed Condorcet to frame a new constitution, which had the honour of obtaining the approbation of the convention; but it did not accord with the views of those whom it was intended to govern; and, in the opinion of others, who were less interested in the decision, it was filled with a series of those politico-metaphysical absurdities, which had been long dazzling the inebriated minds of the republicans. The Mountain Party now began to gain an ascendency over Brissot and his friends. During the violent struggle for power which ensued, Condorcet had the prudence to decline an active part; and, in consequence of his moderation, he was not included in the number who were sacrificed along with Brissot in 1793, when the arrest of the Girondists was decreed. He continued, however, to support his party by his writings, and on this account he incurred the displeasure of Robespierre, who ordered him to be arrested in 1793. Having contrived, however, to evade the vigilance of the officers under whose charge he was placed, he effected his escape, and remained in concealment at Paris during the space of nine months. Alarmed, however, lest a domiciliary visit should be instituted for the purpose of apprehending him, he escaped unobserved through the barriers, and sought refuge on the plain of Mont Rouge, in the house of a friend, who happened unfortunately to be at Paris. He was therefore compelled to spend two nights in the open fields, the victim of cold and hunger; and on the third day, when his friend arrived, he had the mortification of finding that he durst not venture to afford him shelter. Again driven for safety to the woods and fields, Condorcet was at last exhausted with fatigue and hunger, and was forced to apply at a public inn for an omelette, which he greedily devoured. His ghastly appearance and keen appetite having roused the suspicions of a municipal officer who happened to be present, and these suspicions being confirmed by the ambiguity and hesitation of his answers,

* *Pour tout homme qui a lu avec attention l'histoire de l'usurpation de Cromwell, il est evident qu'une seul Gazette eut suffit pour en arreter le succes, il est evident que si le peuple d'Angleterre eut su lire d'autres livres que la Bible, l'hypocrite, demasqué des ses premiers pas, eut bientot cessé d'etre dangereux.*

he was immediately seized and thrown into a dungeon, for the purpose of being conveyed next day to Paris. He was, however, found dead on the morning of the 28th March 1794, in consequence, as was supposed, of having taken poison, a dose of which he always carried about with him. Condorcet was survived by his wife, with whom he had always lived on the most affectionate terms, and by an only daughter, who was married in 1807 to Mr Arthur O'Connor.

Condorcet left behind him some posthumous works, which he had been prevented from publishing by the disorders of the French revolution. His *Esquisse d'un Tableau historique de progres de l'esprit humain* appeared at Paris in 1797, in one volume, and contained the same doctrine of the perfectibility of the human mind, which he had already supported in so many of his works. His other posthumous work is entitled *Moyens d'apprendre à compter surement et avec facilité*, and contains, in small compass, a very beautiful system of elementary arithmetic. It was adopted, by order of the French government, in all the national and private schools, and has been recently (1813) translated into English by Mr Elias Johnston, teacher of mathematics in Edinburgh. This little work is said to have been composed after Condorcet had concealed himself from his enemies, and to have been sent sheet by sheet to his wife.

Beside the works which have already been mentioned, Condorcet published, during his life, *Letters to the King of Prussia.* He was likewise engaged as a contributor to the *Encyclopedie*, and he assisted D'Alembert, Bossut, and La Lande, in writing the mathematical part of that celebrated work. His articles may be distinguished by the signature (M. D. C.) Condorcet had the honour of being elected a member of the Institute of Bologna, and of the Academy of Sciences at Turin.

In reviewing the events of Condorcet's life, it is no difficult matter to form a tolerably correct estimate of his attainments and character. He was deeply and extensively acquainted with the mathematical sciences; and the memoirs which he transmitted on these subjects to the Academy, contain the presages of a greater genius than he ever brought to maturity. As an elegant writer, he was scarcely inferior to his friend and associate the illustrious D'Alembert; and, had his ambition never carried him beyond the bounds of literature and science, his name might have been cherished by posterity, and ranked among those great men who have done honour to their species. But Condorcet aspired at still higher distinction. In the political state of his country, he perceived some distant prospect of reaching the object of his wishes, and he strove, both by his conduct and his writings, to accelerate that dreadful revolution in which he himself was destined to perish. Dazzled with false views of human character, his political writings are marked with opinions the most absurd and extravagant, and subversive of every species of social order and happiness; and, much as we are disposed to reprobate the calumnies which have been heaped upon the most illustrious of the French philosophers, we are compelled to admit, that Condorcet was an infidel, and even an atheist. Although he displayed the utmost courage in his writings, yet, when he was called to act, he evinced the greatest timidity and indecision. The restlessness of his mind instigated him to act a part which he had not fortitude to sustain; and the same timidity of disposition was conspicuous in the manner in which he died. It is impossible to think of the latter days of this celebrated man, without feeling acutely for the sufferings, under the pressure of which he put an end to his life; but it is impossible also not to acknowledge, that he perished in a tumult which he had been the most active to create.

The following is a list of the works written by Condorcet, which are either noticed or printed in the Memoirs of the French Academy:

1 *Traité du Calcul Integral.* 1765, Hist. p. 54.

2. *Du Probleme des trois Corps*, 1767, Hist. p. 93.

3. *Ecclaircissemens sur le Calcul Integral.* 1767, Hist. p. 95.

4. *Sur la nature des suites infinies, sur l'etendue des solutions qu'elles donnent, et sur une nouvelle methode d'approximation pour les equations differentielles de tous les ordres*, 1769, p. 193.

5. *Sur les Equations aux differences partielles*, 1770, p. 108, Hist. p. 69.

6. *Sur les Equations differentielles* 1770, p. 191, Hist. p. 69.

7. *Addition aux Memoires de M. de Condorcet*, p. 108, 151, and 171, of the volume for 1770, p. 615.

8. *Sur la determination des fonctions arbitraires qui entrent dans les integrales des Equations aux differences partielles*, 1771, p. 49.

9. *Reflexions sur les methodes d'approximation, connues jusqu'ici pour les Equations differentielles.* Id. p. 281.

10. *Theoremes sur les quadratures.* Id. p. 693.

11. *Recherches de Calcul Integral.* 1772, p. 1.

12. *Memoire sur le Calcul des Probabilites*, 1781, p. 707.

13. *Suite du Memoire sur le Calcul des Probabilites*, 3d part, 1782, p. 674.

14. *Do. do.* 4th part, 1783, p. 539.

15. *Essai sur le Population du Royaume, par* Messrs Du Sejour, le Marquis de Condorcet, et de La Place, 1784.

16. *Suite du Memoire sur le Calcul des Probabilites*, 1784, p. 454.

17. *Suite de l'Essai pour connoitre le population du Royaume, par* Messrs Du Sejour, le Marquis De Condorcet, et M. de la Place, 1784.

18. *Do.* 1785, p. 661.

19. *Do.* 1786, p. 703.

20. *Do.* 1787, p. 601.

21. *Do.* 1788, p. 755. (*o*)

CONDORE. See Pulo Condore.

CONDUCTORS. See Electricity.

CONE. See Conic Sections.

CONFEDERATION of the Rhine, is the name of an act by which several German states separated themselves from the Germanic body, and associated for their mutual defence under the protection of the Emperor of the French. The deed under which these states were united, was signed at Paris on the 12th of July 1806, and in consequence of this, Francis II. formally abdicated the German empire on the 6th of August 1806.

The following Table contains the states which formed the Confederation at its commencement, with their extent, population, military and political state.

Confederation of the Rhine.

Confederation of the Rhine.

Names of the Kingdoms and Principalities.	Extent in square miles.	Population.	Military State.	Revenue in Florins.
Kingdom of Bavaria, ...	1750	3,290,000	65,000	20,000,000
Do. Wurtemburg, ...	320	1,160,000	18,000	8,000,000
States of the Prince Primate, ...	45	195,000	1,000	1,500,000
Grand Duchy of Baden, ...	265	817,000	10,000	6,000,000
Do. of Cleves and Berg, ...	201	610,000	8,000	2,300,000
Do. of Hesse Darmstadt, ...	196	486,000	9,000	2,500,000
Duchy of Nassau-Usingen, } Do. of Weilbourg, }	95	260,000	6,000	1,900,000
Principality of Hohenzollern-Hechingen, and Siegmaringen, * . . } .	20	50,000	500	300,000
Do. of Salm-Salm, ...	21	36,000 }	400 }	300,000
Do. of Kirbourg, ...	11	18,000 }		
Do. of Isembourg, ...	14	42,000	500	200,000
Do. of Aremberg, ...	50	59,000	400	400,000
Do. of Lichtenstein, ...	2	6,500		20,000
Adjoining states, ...	(102)	(290,000)		(1,250,000)
Principality of Leyen, ...	3	500		130,000
Total, ...	2993	7,034,500	118,800	43,550,000

The following Table contains a list of the states that have recently acceded to the Confederation of the Rhine.

Names of the Kingdoms and Principalities.	Extent in square miles.	Population.	Military State.	Revenue in Florins.
Kingdom of Saxony, ...	750	2,050,000	50,000	13,000,000
Do. Westphalia, ...	710	1,913,400	30,000	12,000,000
Mecklenbourg, Schwerin, †	226	328,636	1,900	1,000,000
Oldenbourg, ...	100	160,000	800	50,000
Mecklenbourg Strelitz, ...	48	70,000	400	300,000
Grand Duchy of Wurtzbourg, ...	96	265,000	6,000	2,500,000
Do. of Saxe-Weimar, ...	37	112,000	800	1,200,000
Duchy of Saxe-Gotha, ...	54	179,000	2,400	1,350,000
Do. Saxe Meiningen, ...	20	50,000	400	450,000
Do. Saxe Cobourg, ...	18	60,000	400	350,000
Do. Saxe Hildbourghausen, ...	12	34,000	200	200,000
Principality of Anhalt Dessau, ...	18	54,000 }		
Do. Bernbourg, ...	17	38,000 }	600	600,000
Do. Cothen, ...	15	32,500 }		
Do. Schwartzbourg, ...	24	55,000 }		350,000
Do. Sunderhausen, ...		}	400	250,000
Do. Rudelstadt, ...	20	56,000 }		200,000
Do. Waldeck, ...	22	48,000	500	400,000
Do. Reuss, ...	24	80,000	400	420,000
Do. Lippe, ...	32	90,000	300	340,000
The three Hanseatic towns (uncertain)	15	210,000	600	1,800,000
Total, ...	8184	5,326,900	93,000	35,610,000

The fate of the following states has not yet been decided.

The countries of Hanover and Lunenburg; of Tecklenbourg, Lingen, Marck, and part of Munster in Westphalia; the provinces of Schmalkalden, Corvey, and Beilstein; the compte of Hainau, and the principalities of Baireuth, Nassau-Dietz-Siegen, Dillenbourg, Fulda, Erfurth with its compte, and Gleichen. The square surface of these states is about 778 miles, their population about 1,600,000, and their revenue 7,995,000.

In the *Almanach du Commerce de Paris*, by Tynna,

* These two principalities are separated in some more recent accounts of the Confederation of the Rhine, and stand thus:—

	Extent in sq. Miles.	*Population.*	*Military State.*	*Revenue.*
Hohenzollern Hechingen, ...	5	13,000	97	50,000 Risdales.
Hohenzollern Siegmaringen, ...	6	14,500	193	66,000 Do.

† The three principalities of Mecklenbourg, Schwerin, Oldenbourg, and Mecklenbourg Strelitz, are inserted on the authority of Reichard, in his *Itineraire de Poche de l'Allemagne et de la Suisse*, published at Paris in 1809; but M. Ockhart in his *Apperçu de l'etat actuel de l'Allemagne*, ranks these principalities among the states that do not belong to the Rhenish Confederation.

Confederation of the Rhine.

for 1811, the Grand Duchy of Warsaw, and the Grand Duchy of Frankfort, are numbered among the states which compose the Confederation of the Rhine. The population of the Grand Duchy of Warsaw is 2,200,000, and its principal towns are Warsaw, Posen, and Bromberg. By the treaty of peace with Austria, in 1809, Western Gallicia, an arrondissement round Cracow, the circle of Zamosc in Eastern Gallicia, and Wielicza, &c. were added to this Grand Duchy.

The Grand Duchy of Francfort is divided into four prefectures, of which the chief towns are, Francfort on the Mayne, Hanau, Aschaffenbourg, and Fulda. Charles Baron D'Alberg, Archbishop of Ratisbon, and Prince Primate of the Confederation of the Rhine, is Grand Duke of Francfort. The population and superficial extent, and the military and financial state of this district, have not yet been ascertained.

The following are the original stipulations which were entered into by the confederated states.

Art. I. The confederated states are for ever separated from the Germanic body, and united by a particular confederation, under the designation of the "Confederated States of the Rhine."

II. Renounce the laws; and,

III. The titles of the empire.

IV. The elector arch-chancellor takes the title of prince primate and most eminent highness, which title shall convey no prerogative derogatory to the entire sovereignty which every one of the contracting parties shall enjoy.

V. The elector of Baden, duke of Berg, and landgrave of Hesse Darmstadt, take the title of grand dukes; the chief of the house of Nassau that of duke; and the count of Leyen that of prince.

VI. The affairs of the confederation shall be discussed in a congress at Frankfort on the Mayne; divided into two colleges, that of the kings and that of the princes.

VII. The members of the league must be independent of every foreign power. They cannot enter into any other service but that of the states of the confederation and its allies. Those who have been in the service of a foreign power, and choose to continue in the same, must abdicate their principality in favour of one of their children.

VIII. Should any prince be disposed to alienate the whole or any part of his sovereignty, he can only do it in favour of a confederate.

IX. All disputes are settled in the assembly at Frankfort, where,

X. The prince primate presides. But if the two colleges deliberate separately, he presides in the college of kings, and the duke of Nassau in the college of princes.

XI. The fundamental statute is to be framed by the prince primate.

XII. The French emperor is protector of the confederation, and names the successor of the prince primate.

XIII. to XXI. Enumerate the cessions made by members of the league: thus, Nassau cedes to Berg the town of Deuss and its territory; Bavaria acquires the imperial city of Nuremberg and its territory: and,

XXII. The prince primate receives Frankfort on the Mayne, and its territory, as his property.

XXIII. and XXIV. Enumerate the lordships over which the members of the confederation exercise the rights of sovereignty.

XXV. They also enjoy the sovereignty over the imperial knightdoms included within their boundaries.

XXVI. The rights of sovereignty consist in legislation, administration of justice, military conscription or recruiting, and levying taxes.

Conferva, Confession.

XXVII. Regulates the patrimonial or private property of the subordinate princes and counts. Their domains cannot be sold or given to any prince out of the confederation, without being first offered to the prince under whose sovereignty they are situated.

XXVIII. These subordinate princes and counts preserve the privilege of being tried by their peers. Their fortune cannot be confiscated, but their revenues may be sequestrated during the life-time of the criminal.

XXIX. and XXX. Regulate the payment of debts.

XXXI. The subordinate princes or counts may take up their residence where they choose, and draw their rents or capitals without any reserve.

XXXII. Public functionaries not retained by the new sovereign, receive a pension proportionate to the situation they held.

XXXIII. The same takes place with respect to religious orders losing their income.

XXXIV. The confederates renounce all reciprocal claims, except the eventual right of succession.

XXXV. Between the Emperor of France and the confederated states there shall be federatively and individually an alliance, by virtue of which every continental war in which either is engaged shall be common to all.

XXXVI. In the event of any power making preparations for war, the contracting parties, in order to prevent surprise, shall, upon the requisition of the minister of one of them at the assembly of the league, arm likewise. And as the contingent of the allies is subdivided into four parts, the assembly shall decide how many are to be called into activity. The armament, however, shall only take place upon the summons of the French emperor to each of the confederates.

XXXVII. The king of Bavaria binds himself to fortify Augsburgh and Lindau, and to form and maintain artillery and baking establishments in the said places.

XXXVIII. The contingent of each confederate is: France 200,000 men, Bavaria 30,000, Wirtemberg 12,000, Baden 8000, Berg 5000, Darmstadt 4000, Nassau, Hohenzollern, and others, 4000, &c.

XXXIX. Admits of the accession of other German princes; and,

XL. as the concluding article, stipulates the exchange of the ratifications. (*o*)

CONFEDERATION, Helvetic. See the article Switzerland.

CONFERVA, a genus of plants of the class Cryptogamia, and order Algæ. See Cryptogamia.

CONFESSION of Faith, simply considered, is the same with creed, and signifies a summary of the principal articles of belief adopted by any individual or society. In its more common acceptation, it is restricted to the summaries of doctrine published by particular *Christian* churches; with the view of preventing their religious sentiments from being misunderstood or misrepresented; or by requiring subscription to them, of securing uniformity of opinion among those who join their communion. Of the lawfulness or expediency of confessions for the latter of these purposes, it is not our intention to treat in the present article; but shall content ourselves with giving a short account of the most distinguished formulas of Christian faith, both ancient and modern; noticing as we go along the chief points in which they agree or differ.

Irenæus, A. D. 180.

Except a single sentence in one of the Ignatian Epistles, which relates exclusively to the *reality* of Christ's personality and sufferings in opposition to the Docetæ,

Confession of Faith.

the earliest document of this kind is to be found in the writings of Irenæus, who flourished towards the end of the second century of the Christian æra. In his treatise against heresies, (lib. i. cap. 2.) this father affirms, that "the faith of the church planted throughout the whole world," consisted in the belief of "one God, the Father Almighty, Maker of heaven and earth and sea, and all that are in them; and one Christ Jesus, the Son of God, who became incarnate for our salvation; and one Holy Spirit, who foretold through the prophets, the dispensations and advents, and the generation by the virgin, and the passion, and the resurrection from the dead, and the ascension in the flesh into heaven, of Christ Jesus our beloved Lord, and his appearing from heaven in the glory of the Father, to unite together all things under one head, and to raise every individual of the human race; that unto Christ Jesus, our Lord and *God*, and Saviour and King, every knee may bow and every tongue confess: that he may pronounce just sentence upon all."

Tertullian, A. D. 200.

In various parts of Tertullian's writings similar statements occur, which it is unnecessary particularly to quote. We shall only remark, that in one of them, the miraculous conception of Christ by the power of the Holy Ghost is distinctly mentioned; that in another, he declares it to have been the uniform doctrine from the beginning of the gospel, that Christ was born of the virgin, both man and God, *ex eâ natum hominem et Deum;* and that in each of these, faith in the Father, Son, and Spirit, is recognised as essential to Christianity. The following passage we cite, for the purpose of marking its coincidence with the Apostles' Creed, to which we shall have occasion soon to advert. "This," says he, "is the sole, immoveable, irreformable rule of faith, viz. to believe in the only God Almighty, maker of the world, and his son Jesus Christ, born of the virgin Mary, crucified under Pontius Pilate, the third day raised from the dead, received into heaven, now sitting at the right hand of the Father, about to come and judge the quick and the dead, by the resurrection also of the flesh." Tertullian *De Virg. vel.*

Origen, 320.

The summaries contained in the works of Origen, nearly resemble the preceding; any difference between them being easily accounted for, from the tenets of the particular heresies against which they were directed. In his Commentary on John's Gospel he thus writes: "We believe that there is one God, who created all things, and framed and made all things to exist out of nothing: We must also believe in the Lord Jesus Christ, and in all the truth concerning his Deity and humanity; and we must likewise believe in the Holy Spirit, and that, being free agents, we shall be punished for the things in which we sin, and rewarded for those in which we do well."

According to Cyprian, the formula, to which assent was required from adults at their baptism, was in these terms: "Dost thou believe in God the Father, Christ the Son, the Holy Spirit, the remission of sins, and eternal life, through the holy church?" This was called by him *Symboli Lex*, the Law of the Creed; and by Novation, *Regula Veritatis*, the Rule of Truth.

Apostles' creed.

From these and similar sources, the different clauses of what is commonly called the Apostles' Creed appear to have sprung. For, though it was long believed to be the composition of the apostles, its claims to such an inspired origin are now universally rejected. Of its great antiquity, however, there can be no doubt; the whole of it, as it stands in the English liturgy, having been generally received as an authoritative confession in the fourth century. Towards the end of that century, Rufinus wrote a commentary on it, which is still extant, in which he acknowledges, that the clause respecting Christ's descent into hell was not admitted into the creeds either of the Western or the Eastern churches; and that the epithet "catholic," was not at that time applied in it to the church. Its great simplicity and conciseness, besides, prove it to have been considerably earlier than the council of Nice, when the heretical speculations of various sects led the defenders of the orthodox faith, to fence the interests of religion with more complicated and cumbrous barriers.

Oriental.

Roman Confession.

The Roman or Western Confession, previous to the fourth century, seems to have been the same with that formerly quoted from Tertullian, with the addition of the articles from the Baptismal Creed, concerning the Holy Spirit, remission of sins, and the church. But that of the Oriental churches, in consequence probably of that philosophising spirit, which most unhappily induced many of their divines to attempt the explanation of subjects altogether beyond the reach of human comprehension, employed various expressions with regard to the divinity and filiation of Christ, which appear to have been for some time peculiar to itself, but which were afterwards adopted in substance by the Nicene fathers.

Nicene, A. D. 325.

In the celebrated council at Nice, in which Arianism was not only condemned but proscribed, the confession established as the universal standard of truth and orthodoxy runs thus: "We believe in one God, Father Almighty, Creator of heaven and earth, and of all things visible and invisible; and in one Lord Jesus, the only begotten Son of God, begotten of the Father, or essence of the Father, before all ages, God of God, Light of Light, true God of the true God, begotten not made, consubstantial or coessential (ὁμοουσιος) with the Father; by whom all things were made; who for us men, and for our salvation, descended from heaven, and became incarnate by the Holy Spirit, of the virgin Mary; and was made man, was crucified for us under Pontius Pilate, suffered, and was buried; and rose again the third day according to the Scriptures, and ascended into heaven, and sits at the right hand of the Father, and will come again with glory to judge the quick and the dead, of whose kingdom there will be no end: And in the Holy Spirit who spake by the prophets: And in one holy, universal, and apostolical church. I confess one baptism for the remission of sins. I expect the resurrection of the dead, and the life of the world to come."

Arian.

It were endless to specify the particular shades of difference by which the Arian confessions, (the number of which amounted nearly to twenty in the space of a very few years), were distinguished from each other. Suffice it to say, that while they agreed generally in substance, especially in rejecting the Nicene term ὁμοουσιος, as applied to the Son, their variations of expression concerning the nature of his subordination to the Father, were so astonishingly minute, as almost to bid defiance to any attempt which might be made, at this distance of time, to determine in what their real and essential differences consisted.

Constantinopolitan, A. D. 381.

Macedonius having denied not only the divinity but the personality of the Holy Spirit, maintaining that he is only a *divine energy* diffused throughout the universe, a general council was called at Constantinople, A. D. 381, in order to crush this rising heresy. The confession promulgated on this occasion, and which "gave the finishing touch to what the Council of Nice had left imperfect, and fixed in a full and determinate manner the doctrine of the Trinity, as it is still received among the generality of Christians," exactly coincides with the

Confession of Faith.

Nicene confession, except in the article respecting the Spirit, which it thus extends,—" And in the Holy Spirit, the Lord, and Giver of life, who proceeds from the Father and the Son, who is adored and glorified together with the Father and the Son."

Athanasian Creed.

Subsequent to this, and probably towards the middle of the 5th century, the creed which bears the name of Athanasius, appears to have been composed. That it was not the work of this distinguished opposer of Arianism, is established by the most satisfactory evidence. No traces of it are to be found in any of his writings, though they relate chiefly to the very subject of which it is an exposition; and so far from its being ascribed to him, not the least notice is taken of it, by any of his contemporaries. Its language, besides, concerning the Spirit, is so similar to that of the Council of Constantinople, but still more precise and explicit, that there can be no doubt of its having been written posterior to the time of that assembly. Yet Athanasius died in the year 373. Accordingly, it has been, with great probability of truth, attributed, particularly by Dr Waterland, to Hilary, Bishop of Arles, who is said by one of his biographers, to have composed an *Exposition* of the Creed; a title which certainly is more appropriate and characteristic of it, than that of Creed simply, by which it is now so universally known. Its contents we need not mention, as it is to be found in almost every copy of the English liturgy; and, indeed, is frequently used in the episcopal service. We shall only notice farther, that its damnatory clauses have long been the subject of just regret; and that definite and minute as its statements are, it has done nothing whatever to settle the controversies which have been agitated on the subject of the Trinity.

Before leaving the *ancient* formulas of Christian doctrine, it may be stated, that both in the Council of Ephesus against the Nestorians, held A. D. 431, and in that of Chalcedon against the Eutychians in 451, it was solemnly declared and decreed, that " Christ was *one* divine person, in whom two natures, the human and the divine, were most closely united, but without being mixed or confounded together."

Roman Catholic. A. D. 1553.

Amid the variance and opposition of council to council and pope to pope, which prevailed for centuries in the Romish church, it would be no easy task to ascertain the real articles of its confession. The decrees of the council of Trent, however, together with the creed of Pope Pius IV. are now commonly understood to be the authoritative standards of its faith and worship. These, besides recognising the authority of the apostles' and the Nicene creeds, embrace a multitude of dogmas which it is unnecessary particularly to specify, relating to traditions, the sacraments of baptism, confirmation, eucharist, penance, extreme unction, order, and matrimony, transubstantiation, the sacrifice of the mass, worshipping of images, purgatory, indulgencies, &c. &c.

Greek Church.

The Greek church has no public or established confession; but its creed, so far as can be gathered from its authorised catechisms, admits the doctrines of the Nicene and Athanasian creeds, with the exception of the article in each concerning the procession of the Holy Spirit, which it affirms to be " from the Father only, and not from the Father and the Son." It disowns the supremacy and infallibility of the pope, purgatory by *fire, graven* images, and the restriction of the sacrament to one kind; but acknowledges the *seven* sacraments of the Catholics, the *use* of pictures, invocation of saints, transubstantiation, and masses and prayers for the dead.

Though the Romish church early appropriated to itself the exclusive title of catholic, or universal, and though, for many centuries, its unscriptural tenets pervaded the far greater part of Europe, not only were there always some individuals who adhered to the doctrines of genuine Christianity, but, long before the Protestant reformation, there appear to have been whole congregations who maintained, in considerable purity, the substance of the faith contained in Scripture. Such were the churches of the Waldenses in the vallies of Piedmont, whose confession, of so early a date as the beginning of the 12th century, is still preserved. It consists of 14 articles, in which the authority of the apostle's creed, and of the canonical books of Scripture alone, and the doctrines of the Trinity, the fall, original sin, the atonement of Christ, and free unmerited salvation by him as the only mediator, are distinctly asserted; and the popish tenets of human tradition, purgatory, seven sacraments, invocation of saints, mass, and other " antichristian inventions," are declared to be " an abomination."

Waldenses, A. D. 1120.

Augsburg, 1530.

The *first* Protestant confession was that presented in 1530, to the diet of Augsburg, by the suggestion, and under the direction, of John, Elector of Saxony. This wise and prudent prince, with the view of having the principal grounds on which the Protestants had separated from the Romish communion, distinctly submitted to that assembly, intrusted the duty of preparing a summary of them to the divines of Wittemberg. Nor was that task a difficult one; for the reformed doctrines had already been digested into 17 articles, which had been proposed at the conferences both at Sultzbach and Smalcald, as the confession of faith to be adopted by the Protestant confederates. These, accordingly, were delivered to the elector by Luther, and served as the basis of the celebrated Augsburg confession, written " by the elegant and accurate pen of Melancthon;" a work, which has been admired by many, even of its enemies, for its perspicuity, piety, and erudition. It contains 28 chapters, the leading topics of which are, the true and essential divinity of Christ; his substitution and vicarious sacrifice; original sin; human inability; the necessity, freedom, and efficacy of divine grace; consubstantiation, and particularly justification by faith, to establish the truth and importance of which was one of its chief objects. The last seven articles condemn and confute the popish tenets of communion in one kind, clerical celibacy, private masses, auricular confession, legendary traditions, monastic vows, and the exorbitant power of the church. This is the universal standard of orthodox doctrine among those who profess to be Lutherans, on which no authoritative alteration has ever been made.

Basil, 1534

The confession of Basil, originally presented like the preceding to the diet of Augsburg, but not published till 1534, consists of only 12 articles, which, in every essential point, agree with those of the Augsburg confession, except that it rejects the doctrine of consubstantiation, affirming that Christ is only spiritually present in the Lord's supper, *sacramentaliter nimirum, et per memorationem fidei;* and that it asserts the doctrine of predestination and infant baptism. But the more detailed creed of the whole Swiss Protestant churches, is contained in the former and latter Helvetic confessions. The first was drawn up in 1536, by Bullinger, Myconius and Grynæus, in behalf of the churches of Helvetia, and presented to an assembly of divines at Wittemberg, by whom it was cordially approved. But being deemed too concise, a second was prepared in 1566, by the pastors of Zurich, which was subscribed not only by all the Swiss Protestants, but by the churches of Geneva and Savoy, and by many of those in Hunga-

Helvetic, 1536.

1566.

Confession of Faith.

ry and Poland. They fully harmonise with each other, with only this difference, that the doctrine of predestination, and an approbation of the observance of such religious festivals as the nativity, &c. are to be found in the latter confession only.

Bohemic, 1535, The Bohemic confession was compiled from various ancient confessions of the Waldenses who had settled in Bohemia, and approved of by Luther and Melancthon in 1532; but it was not published till 1535, when it was presented by the barons and other nobles to king Ferdinand. It extends to 20 articles, similar to those of the Waldensian confession, with the addition of others on the divinity of Christ, justification by faith in him, "without any human help or merit," predestination, and the absolute necessity of sanctification and good works.

Saxon, 1551. The confession of the Saxon churches was composed in 1551 by Melancthon, at the desire of the pastors of Saxony and Misnia met in assembly at Wittemberg, in order to be presented to the Council of Trent. It is contained in twenty-two articles: and whilst, like that of Augsburg, it is silent on the subject of predestination, it lays equal stress on the doctrine of justification by faith, and has a separate article entitled "Rewards," in which the doctrine of human merit, particularly as connected with future blessedness, is condemned and refuted.

English, 1553. The first draught of the English confession was prepared by Archbishop Cranmer in 1551, with the assistance of Bishop Ridley; and after being revised by Knox and Harley, and others of the Scotish reformers, corrected by the English bishops, and approved by convocation, it was published both in Latin and English, in the year 1553. Its articles were at first 42 in number, but on being revised in 1562, they were reduced to *thirty-nine,* and then published in Latin only; no authentic English copy of them having been edited till

1571. 1571, when they were again revised by the convocation, and authoritatively published in their present form. They are so generally known, being inserted in most of the Common Prayer Books, that any statement of the doctrines which they contain is quite unnecessary here. We shall only observe, with regard to their Calvinistic complexion, a subject which has, of late years, been agitated with uncommon keenness and ability, that the English delegates at the Synod of Dort certainly believed them to be Calvinistic, otherwise it can scarcely be supposed that they would have gone along with the doctrinal sentiments of that assembly, particularly on the topic of *unconditional* election; and that it is generally understood, that all who are unconnected with the Church of England have no hesitation in numbering the 39 articles among Calvinistic confessions.

French, 1559. The confession of the Reformed Gallican churches was prepared by order of a synod at Paris in 1559; and presented to Charles IX. in 1561, by the celebrated Beza, in a conference with that monarch at Poissy. It was published for the first time in 1566, with a preface by the French clergy, to the pastors of all Protestant churches; and afterwards in 1571, it was solemnly ratified and subscribed in the national synod of Rochelle. It is extended to forty articles; but they are in general concise, and embrace the usual topics of the other Protestant confessions, including the doctrines of election, and justification by faith only.

Scotish, 1560. The Protestants in Scotland having presented a petition to parliament in 1560, requesting the public condemnation of popery, and the legal acknowledgment of the reformed doctrine and worship, they were required to draw up a summary of the doctrines which they could prove to be consonant with scripture, and which they were anxious to have established. The ministers on whom this duty was devolved, being well acquainted with the subject, prepared the required summary in the course of four days, and laid it before parliament, when, after having been read first before the Lords of the Articles, and afterwards twice, (the second time article by article) before the whole parliament, it received their sanction as the established system of belief and worship. It consists of twenty-five articles, and coincides with all the other Protestant confessions which affirm the doctrine of election, and reject that of consubstantiation; for though it is not so explicit as some of them respecting the *unconditional* nature of election, yet a distinct recognition of this doctrine pervades the whole of it; and though it has no separate article on justification, it no less distinctly recognises this fundamental principle of the Protestant faith.

The tenets of Arminius having obtained considerable prevalence in Holland towards the beginning of the 1618-19. 17th century, the Calvinists, or Gomarists as they were then called, appealed to a national synod which was convened at Dort in 1618, by order of the States-General; and attended by ecclesiastical deputies from England, Switzerland, Bremen, Hesse, and the Palatinate, besides the clerical and lay representatives of the reformed churches in the United Provinces. The canons of this synod, contained in five chapters, relate to what are commonly called the *five points,* viz. particular and unconditional election; particular redemption, or the limitation of the saving effects of Christ's death to the elect only; the total corruption of human nature, and the total moral inability of man in his fallen state; the irresistibility of divine grace; and the final perseverance of the saints; all of which are declared to be the true and the only doctrines of scripture.

The only other confession of which we shall take notice, is that of the Westminster assembly, which met in Westminster Assembly, 1643. 1643, and at which five ministers and three elders as commissioners from the General Assembly of the Church of Scotland attended, agreeably to engagements between the convention of estates here, and both houses of parliament in England. This confession is contained in thirty-three chapters, and in every point of doctrine exactly accords with the sentiments of the Synod of Dort. It was approved and adopted by the General Assembly in 1647; and two years after, ratified by act of parliament, as "the public and avowed confession of the Church of Scotland." By act of parliament 1690, 1690. it was again declared to be the national standard of faith in Scotland; and subscription to it as "the confession of his faith," specially required of every person who shall be admitted "a minister or preacher within this church." Subscription to it was also enjoined by the act of union 1707, on all "professors, principals, regents, masters, and others bearing office," in any of the Scottish universities.

On the subject of the preceding article, see *Eusebius;* Mosheim's *Ch. History;* King's *Hist. of the Apostles' Creed;* Waterland's *Critical Hist. of the Athanasian Creed;* Rycaut's *Greek Church;* Morland's *Hist. of the Churches of Piedmont;* the English *Harmony of Confessions;* Corpus et Syntagma *Confessionum;* Kœcheri *Biblioth. Theolog. Symbolicæ;* Buddæi *Isagog. Historico-theolog.;* and Adam's *Religious World Displayed.* (*d*)

Confucius.

CONFUCIUS, or KONG-FOO-TSE, the celebrated Chinese philosopher, was born about 550 years before the

Confucius. Christian æra, in the kingdom of Loo, now the province of Shan-tong, in the reign of Lin-vang, the twenty-third emperor of the dynasty of Tcheoo. By his mother's side, whose name was Shing, he was descended from the noble family of Yen; and his father Tcho-leang-hee numbered among his progenitors the Emperor Tii, of the dynasty of Shang. When he was only three years of age, he was left, by the death of his father, with no other inheritance than those honours of descent; and for no part of his future eminence, was he indebted to the wealth or grandeur of his ancestors. He gave early indications of those exalted talents, by which he was afterwards so much distinguished; and the most marvellous accounts of his premature attainments are minutely detailed by the Chinese historians. Even in infancy, he seemed to have acquired the maturity of reason and the perfect use of all his faculties. He took no pleasure in the amusements of childhood; but was remarkable, almost from his birth, for the gravity of his deportment. He was particularly celebrated for extraordinary piety; and never partook of any kind of nourishment, till he had first prostrated himself on the ground, and made an offering of the food to the supreme Lord of heaven. After the death of his grandfather, a most holy man of those times, whom he had studied to imitate in all things, he put himself under the tuition of an eminent sage, named Tchemsée; and, at fifteen years of age, devoted himself to the perusal of the ancient Chinese books, especially the writings of the royal legislators Yao and Shun. At the age of nineteen, he entered into the married state; and, contrary to the custom of his country, contented himself with one wife, whom he divorced very soon after marriage, that he might be completely free from every incumbrance and connection, which might fetter him in the propagation of his tenets. He had one son named Pe-yoo, who died in middle age, leaving also one son, named Tsoo-tse, who inherited the virtues of his grandfather, and afterwards attained the highest offices in the state.

At the age of twenty-three years, Confucius, having acquired a profound knowledge of the ancient history and laws of the empire, began to attempt a general reformation of manners among his countrymen. In opposition to the boundless luxury and inordinate love of pleasure which everywhere prevailed, and which threatened the utter ruin of the several kingdoms which then composed the empire of China, he taught a system of the strictest morality, and enforced his doctrines by the purity of his own example. By his extraordinary knowledge and amiable virtues, he speedily acquired the most extensive celebrity, and was frequently invested with the highest offices in the magistracy, which he sometimes accepted, when he conceived that they might be made subservient to his plans of reformation; but which he always resigned, whenever he was unable to exercise them with any beneficial effect. As his success, however, did not correspond with his expectations and endeavours, he at length renounced all his dignities in his native country, and went to seek in other parts of the empire a more favourable reception to his precepts. But, in the 55th year of his age, he returned to his native country, the kingdom of Loo, where he was instantly invested with one of the principal offices in the government; and where he is said, in the short space of three months, to have effected, by his counsels and good example, an entire reformation of manners, both among the higher and lower orders of the subjects. The prince put himself and his court under the direction of the philosopher; and the whole kingdom had the appearance of a well-regulated family. The prosperous state of the country, in consequence of these political and moral improvements, excited the jealousy of the neighbouring princes, and filled them with apprehensions, that its growing power might soon become more formidable than was consistent with their security. The king of Tsi, in particular, held frequent consultations with his nobles upon the subject, and at length devised the following scheme for defeating the enlightened measures of Confucius. Upon pretence of sending a friendly embassy, he presented to the prince of Loo and his grandees, a number of the most beautiful young women, who had been carefully instructed in the arts of dancing, singing, and all those other accomplishments which so powerfully enslave the hearts, and enervate the minds of men. In spite of all the remonstrances of Confucius, the fair strangers experienced a welcome reception from the prince of Loo and his principal officers at court; and all the affairs of government were speedily banished from their thoughts by the succession of feasts and diversions into which they were plunged, without a moment's intermission, by the fascinations of their new favourites. The sovereign, deaf to every sound but the voice of pleasure, could not endure to be addressed on points of public concern; and even refused at length to admit his most faithful ministers to his presence. The philosopher attempted in vain to stem this torrent of dissipation which inundated the court, and which sufficiently proved the slight impression which his instructions had made. Finding all his struggles utterly ineffectual, he resolved to resign his employments, and to become once more a voluntary exile from his degenerate country.

He passed in his progress through the kingdoms of Tchi, Goo-shi, and Tsoo, without receiving the slightest encouragement to take up his residence in any of their cities. The austere integrity of his politics, and the strict simplicity of his manners, rendered him everywhere rather an object of dread; and he was generally regarded by the leading men of every province, both as a dangerous associate, who would speedily undermine their influence by his superior talents, and also as a troublesome monitor, who would perpetually disturb their pleasures by his virtuous reproofs. He often experienced the most contemptuous treatment from the more licentious nobles; and conspiracies even were in some instances formed against his life. By totally neglecting his personal interests, he found himself reduced at length to a state of extreme indigence, and was compelled to resume his original office of a private instructor. Declining the invitation of certain sages of his time, to withdraw from the world, and lead the life of a hermit, he resolved to devote himself to the improvement of the lower classes of the people. Ceasing, therefore, to address himself to the inhabitants of palaces, and the attendants of courts, he employed the remaining part of his life in making the most distant and fatiguing journies throughout the Chinese empire, instructing every where persons of every rank, who were willing to listen to his precepts. And as in all his discourses, he was continually producing the maxims and example of the ancient Chinese worthies, Yao, Shun, Yu, Tching-tang, and Ven-vang, he began to be regarded as in a manner the representative of these imperial sages, and at length attracted around him a considerable number of followers.

Besides his general admirers, he is said to have had above three thousand disciples, who were more particularly attached to his person and principles. These he distributed into four classes; the *first* consisting of those who devoted themselves to the cultivation of their minds by frequent meditation, and to the improvement of their hearts by the sentiments of virtue; the *second*, of those who addicted themselves to the study of just reasoning, and to the practice of eloquent composition; the *third*, of those who employed themselves in investigating the principles of good government, and instructing the mandarins in their duties; and the *fourth*, of those who exercised their powers in communicating to the people, in a clear and polished style, the precepts of practical morality. All these disciples were understood as engaged, in their respective stations and pursuits, in cultivating and extending the philosophy of their master; and five hundred of his pupils are said to have attained, during his life, the highest offices of government in the different kingdoms of China. Seventy-two of that number were selected as a kind of honorary class, who were distinguished by the superiority of their attainments; and again, ten out of these are celebrated as the most perfect, who had reached the full comprehension of the philosopher's system. One of these, particularly, named Yen-yuen, was the most favoured of his pupils; and his death, at the early age of thirty years, is said to have afflicted him with more poignant and lasting grief, than any other calamitous occurrence in the course of his protracted and eventful life.

Confucius, during the latter part of his life, sent 600 of his disciples through the different provinces of China, to disseminate his tenets, and reform the manners of the people; and is said to have even formed the design of propagating his doctrines in foreign countries. His reputation and success, however, while he was alive, appear, even from the Chinese accounts, to have been extremely limited and variable, and to have depended more upon the favour of the individual princes, by whom he was occasionally patronized, than upon any real attachment to his principles among his contemporaries. When he was invited to the palace, and honoured with the notice of any of the petty sovereigns in the empire, it became the fashion of the court, and, in a manner the law of the kingdom, to admire his instructions, and extol his character. But, upon the decease of his royal patrons, or the decay of their attachment, he frequently experienced a total revolution in his affairs, and found his precepts despised, and his person in a manner proscribed in those very places, where he had been revered as the fountain of all wisdom, and the example of every virtue. The courtiers, on such occasions, who had envied his influence, and disliked his restraints, made him the subject of their songs and satires; and the changeable multitude, following the example of their superiors, assailed him openly with the most insolent revilings. He appears, indeed, before his death, to have lost all his influence, and to have retained the affections only of a few disciples, who were more immediately attached to his person. This is sufficiently confirmed by the circumstances related of his latter days, and the expressions ascribed to him on his death-bed by his most ardent admirers. According to their united testimony, he spent the three concluding years of his life in retirement and sorrow. A short time before his last illness, he told his disciples, with tears in his eyes, that he was overwhelmed with grief, on account of the great disorders which every where prevailed throughout the empire. "The mountain," he added, "is fallen, the high machine is demolished, and all the sages have disappeared;" by which he intimated, that the edifice of perfection, which he had endeavoured to raise, was almost completely overthrown. From this period, he began to languish; and, on the seventh day before his death, again addressed his attendants in similar terms of despondency: "The kings refuse to follow my maxims; and since I am no longer useful on the earth, it is as well that I leave it." He then sunk into a lethargy, which continued for the space of seven days, when he expired in the arms of his disciples, in the 73d year of his age, and about 479 years before the birth of Christ.

No sooner was he dead, than the veneration for his name began to revive; and the prince who then reigned in Loo, whose name was Ngai-kong, upon receiving intelligence of his decease, is said to have burst into tears, exclaiming at the same time, "The Tien is displeased with me, since he has taken away Confucius." His disciples clothed themselves in habits of mourning, and lamented his loss, as they would have done that of a parent. His sepulchre was erected near the city of Kio-feoo, the supposed place of his nativity, upon the banks of the river Loo, where he used to assemble his pupils. His descendants possess the rank of nobility; and he receives throughout the vast empire of China, not indeed divine honours, as some have affirmed, but that secondary species of worship which the Chinese are accustomed to offer to tutelary spirits, and to the manes of their ancestors. In almost every city and village, a plain building or chapel is erected to his memory, called "The house of Confucius," in which is placed a simple tablet, with inscriptions in gilt letters to this effect: "O Confucius, our revered master, let thy spiritual part descend, and be pleased with this tribute of respect, which we now humbly offer thee." Wine, fruits, flowers, and perfumes are placed before the tablet; incense is burned; tapers of sandal-wood lighted; and the same ceremonies observed, as in the honours which are paid to deceased ancestors. These offerings in the temples of Confucius are made chiefly by the literary young men, when they are about to undergo their public examinations; but the memory of the philosopher is held in estimation by all classes of the Chinese, who regard him as, without exception, the most eminent sage, and the wisest legislator that ever appeared, either in their own or in any other nation. His name is interwoven with almost every civil institution or observance in the Chinese empire; and his doctrine is considered as the only foundation of all political wisdom, or moral virtue.

With respect to his personal appearance, he is described by his Chinese biographers, as having been of a tall stature, and a well proportioned form, with an olive complexion, large eyes, a flat nose, a long and black beard, a broad chest, and a sharp strong voice. His countenance was rather disfigured, by a swelling in the middle of his forehead; from this circumstance, he received from his father the sirname of Kieoo, or "little hill;" a designation which he used frequently, in modesty or in jest, to apply to himself, even during the period of his highest renown.

In his moral character, he is represented as having been a pattern of integrity, temperance, and contempt of sublunary wealth; and as having invariably exemplified in his own conduct the precepts of virtue, which he publicly inculcated. He is likewise celebrated on account of the unequalled fortitude and equanimity with which he sustained every reverse of his fame or fortune; and the following instance of his pious composure, in situations of the most imminent danger, is

Confucius.

frequently cited by his admirers in China. An officer of the army, named Hoan-tee, enraged by the restraints, which the precepts and presence of Confucius imposed upon him and his associates, made a daring assault upon the philosopher in open day with a drawn sabre, but happily failed in his attempt to inflict a mortal blow. The intrepid sage, in the mean time, discovered not the smallest emotion or symptom of dread; and when his terrified followers besought him to hasten from the presence of the brutal mandarin, he is said to have calmly replied in these words: "If the Tien protects us, of which he has just given a sensible proof, what harm can the rage of Hoan-tee do to us, although he be the president of the tribunal of the army?" This bold and undaunted spirit was united, we are told, with the most gentle temper and humble disposition of mind, which frequently led him to disclaim the high praises that were bestowed upon him, and to lament, on the contrary, his numerous deficiencies. His doctrine, he used to say, was not his own, but was derived from the ancient sages, particularly from those wise legislators, Yao and Shun. "There are four things," he frequently said to his more favoured disciples, "which give me continual uneasiness; the first, that I have made so little progress in virtue; the second, that I am not sufficiently eager in the prosecution of my studies; the third, that I am not more devoted to the duties of justice; the fourth, that I am not duly watchful over my own heart and actions." Being informed one day, that he was generally denominated *king*, which, in the Chinese tongue, signifies *wisest*, he replied, "I deserve no such encomium, and I can by no means suffer it. All the good that can be said of me is, that I do my utmost to acquire wisdom and virtue, and that I am not discouraged by the difficulties which I encounter in teaching them to mankind." The following epitome of his character is current among his disciples in China, namely, that he united in himself three things, which appear most incompatible with each other; all the grace of a polite behaviour, with a great deal of gravity; a stern aspect, with a great deal of good nature; and an extraordinary elevation of soul, with a great deal of modesty.

These details of the life and character of Confucius rest entirely upon the authority of the Chinese writers, and may naturally be conceived to partake, in some respects, of their characteristic exaggeration in whatever relates to the honour of their nation. But of the nature of his doctrines, a more impartial judgment may be formed from his own writings, which have been faithfully preserved, and which compose the greatest portion of the classical or canonical books of the Chinese. For a general view of his principal tenets, the reader is referred to the article China in this work, p. 248; and to p. 276, for an account of those sacred books, among which his writings are classed. The productions of his pen, which rank in the first class of the *King*, or canonical books, are, 1. A commentary on the lines of Fo-shee, in which he details a species of divination or fortune-telling, and which forms the principal part of the book Y-king: 2. The whole of the second canonical book, called Shooking, a collection of the earliest historical records of the Chinese nation, of which Confucius professes only to be the editor, but of which he is suspected to have been in reality the author: 3. A book of his maxims, collected by his disciples, and forming part of the canonical book called Lee-kee: 4. The whole of the fifth canonical book, called Tchun-tsieoo, consisting of the annals of his native country, the kingdom of Loo, commencing 722 years before Christ. His other writings, which are arranged in the second class of *King*, or classics, are known under the title of See-shoo, or "the four books" of Confucius, viz. Ta-hio, or sublime science; Tchong-yong, or just medium; Lun-yu, or words and discourses; and Meng-tse, or the book of Mencius, one of his disciples. Of the contents of the three first of these pieces, a slight sketch may be found in Du Halde's History of China, vol. iii. p. 303. of the English translation, published in London in the year 1736; and an English translation of the first, viz. Ta-hio, has been very recently published by the Rev. R. Morrison, Protestant missionary at Canton, in a work entitled *Horæ Sinicæ*. Two other books, considered as the production of this philosopher, are held in great repute, and are more generally perused among the great body of his countrymen, than his writings of a higher class. These are Hiao-king, which treats of filial reverence, or the respect due to parents; and Siao-hio, that is, "the science or school of children," a collection of sentences and examples from various authors. These two pieces have been translated into Latin by Father Noel, one of the earliest missionaries in China, and were printed at Prague in 1711. See Du Halde's *History of China*, vol. iii. p. 293; *Modern Universal History*, vol. viii. p. 104; *General Biographical Dictionary*; Enfield's *History of Philosophy*, vol. ii.; D'Anquetil's *Hist. Universelle*; Le Compte's *Memoirs of China*; Martinii *Historia Sinica*, lib. iv.; Barrow's *Travels in China*; and Morrison's *Horæ Sinicæ*. (*q*)

CONGELATION. See Cold and Meteorology.

CONGLETON, a small corporate town of England, in the county of Chester, situated on the borders of Staffordshire, on the upper part of the river Dane. The houses are principally situated in one street, and, in general, are remarkably neat and elegant. There are two churches here which are subject to the church of Astbury, a village about two miles distant, where there are two ancient stone monuments, decorated with the insignia of knighthood. This town was formerly celebrated by its manufacture of tagged leather laces, called Congleton points, but the poor are principally employed in a handsome silk mill built upon the Dane; in a manufacture of ribbands, which are sold to the merchants in Coventry, and in a manufacture of gloves and purses. In the neighbourhood of Astbury, there are large lime quarries, and the lime is burnt by coals obtained on purpose from Staffordshire. This limestone, which is of an ash grey colour, is heavier than that of Buxton, and is preferred as a manure by the farmers.

According to the population returns for 1811, the town of Congleton contains,

Inhabited houses	944
Families that occupy them	986
Houses uninhabited	30
Families employed in agriculture	158
Families employed in trades and manufactures	753
Males	2023
Females	2593
Total population in 1811	4616
Do. 1801	3861
Increase	755

CONGO, a kingdom of Africa, bounded on the north by the river Zair, or Congo, which divides it from Loango; on the south by the river Danda, which separates it from Angola; on the east by the kingdoms of Fungo- Boundaries.

Congo.

no and Melamba, and the burnt mountains of the sun, (those of crystal, or saltpetre, and silver,) and by the rivers Verbela and Chilandea; and on the west by that part of the Atlantic Ocean called the Ethiopic Sea, or the Sea of Congo. According to this definition of its limits, Congo Proper extends about three degrees from north to south, lying on the coast between 8° and 9° south lat. but widening in its breadth inland with the course of the river Zair, which runs winding above 2° more to the north. Both however in this direction, and still more in that of its length from east to west, its dimensions are very uncertain, no exact observations having been taken of the precise position of those natural boundaries within which it is contained. According to the relation of John Anthony Cavarri de Monte Cuculo, a capuchin missionary, the dominions of the kings of Congo were much extended towards the east and south, before the introduction of the Christian religion; whereas, since that event, many of the remote provinces, in these directions, having been dismembered from it, it was reduced, in consequence, from above 600 leagues in circuit, to less than one half of that extent. Dr Brookes and Mr Walker state it to be 150 miles long, and 372 broad.

Divisions.

Congo is divided into six large provinces, of which the county of Sogni, and the great duchy of Bamba, stretch along the sea coast; the duchy of Lundi, and the marquisate of Pango, are situated towards the north; the marquisate of Pemba is within land, and to the west is the duchy of Batta. These provinces are subdivided into lesser seignories, or lordships. Besides those principal divisions, there are comprehended under the same general denomination several other lesser provinces, most of which are covered with forests or mountains, and inhabited by races of men in a state the most uncultivated and savage.

Rivers.

The principal rivers of this country are the Zair, already mentioned, with the Dando. In the intermediate parts between these are the Lehundo, Doce, Ambrez, Loze, Onzo, and Lutana, with several others of less note. There is, besides, a considerable number of tributary streams of some moment, flowing chiefly into the Zair, such as the Bancaro, the Vambra, the Congo, and the Barbela.

Climate, Seasons, &c.

Congo Proper, being situated within the torrid zone, is liable to excessive heats. These, however, are considerably mitigated by winds and breezes, rains and constant dews, the effect of which is at the same time farther favoured by the greater equality in those latitudes in the length of the days and nights. The summer and the winter, which compose the year of the Congoese, are divided by them into six seasons, which they distinguish by the names *Massanza, Neasu, Ecundi, Quitombo, Quibiso,* and *Quimbangala*. The first four of these comprehend what may be called their summer. At the commencement of this period, which corresponds to our month of October, the rains begin to fall in those countries, and they continue during the two, and sometimes the three next months. The floods which are thus occasioned, are commonly succeeded by a famine, the low lands being overflown by them, and the corn carried off; while, notwithstanding the frequency of such misfortunes, by which it might have been expected that experience would have been gained, and better habits induced, the inveterate sloth of the inhabitants continues such, that due care is seldom taken to make any proper provision against such disasters. Neasu begins about the end of January, when the produce of the lands has arrived at its full height, and wants but a few days of being ripened for harvest. The first crop is no sooner gathered in, than the fields are sown anew, two harvests being commonly obtained here in the course of the year. The third and fourth seasons are frequently (if such an expression may be used) blended together towards the middle of March, when the more gentle rains begin to fall, and continue to do so till the month of May. The principal distinction between these two seasons, or the parts of them, consists in the greater or lesser quantity of rain that falls during their progress. During the rest of the time in which the rains do not prevail, the air is clear and dry, while the clouds, being overcharged with electric matter, burst out occasionally into the most terrible thunders and lightnings, without yielding, though they seem loaded with it, the least drop of rain. These seasons taken together, last till about the beginning, or sometimes till the end of September. The two last seasons, Quibiso and Quimbangala, constitute the short winter of this country, of which the distinguishing features are not frost or snow, which are unknown in these regions, but dry blasting winds that strip the earth of its verdure, and induce a general face of deadness and desolation, till with the return, in the appointed time, of the next massanza, or spring, the vernal bloom is restored. The weather is, during this period, considered by the natives as cold, though to those accustomed to the regions of the northern European climates, it would on the contrary appear rather hot. By another division of time recognised among the Congoese, the year is made to consist of 12 lunar months, beginning, like the year of the Jews, with the month of September. They have also weeks, but consisting of four days only, three of which are appointed for labour, and the fourth for rest or religious exercises.

Mineral productions.

Congo is said by some of those who have visited it, to be very rich in mineral productions. According to Josser, its mountains yield in several places very fine stone for building, which may, moreover, be obtained of an extraordinary magnitude. There are here also even entire mountains of porphyry, of jasper, and of marbles of different colours, which in Italy are known by the name of the marble of Numidia, of Africa, and of Ethiopia. In the same mountains there is found a kind of stone containing beautiful hyacinths diffused over the mass, previously to the separation of which it might be formed into columns of the greatest beauty. Among other articles of rare produce in this department, there are mentioned various stones that appear impregnated with copper and other metals, which receive the finest polish, and are of admirable use in sculpture and engraving. Mines of copper of an excellent quality are very frequent in Congo. It is particularly prevalent in the province of Bemba, near to the city of the same name. In Sogni, it is hardly less abundant; and the copper of that district, being even better than that of Bemba, it is used at Loanda in the fabrication of bracelets and rings, which are in the way of trade transported to Kallabar, Kiodelkey, and other places. Linschoten asserts, that in Bamba there are mines of silver, and some other metals, and that at Lundi there are found mines of crystal and of iron. The last, he says, are the most highly esteemed of the negroes, because of that metal they make their knives, swords, and other arms. It has been imagined by some, that there are immense treasures of precious stones concealed in this country. Dapper seems satisfied, from different assurances which he had received on the subject, that it contains mines of gold, particularly in the

Congo.

vicinity of the capital. Carli and Lopez agree with him in opinion as to the existence in the country of such mines; but if the fact actually be so, it would appear, at least, that they have hitherto escaped the keen-sighted avarice, in respect to such objects, of the Europeans who have settled in that quarter; a circumstance for which, indeed, it has been endeavoured, though it may be judged by some rather unsuccessfully, to account.

Soil.

The soil of Congo is naturally very fertile. The principal article of its vegetable produce is rice, which grows here in great abundance, as does also Indian corn, barley, and beans. The Indian wheat grows very strong, and is very well filled. This being ground, is made into bread, or boiled with water into a kind of pap. The other sorts of grain raised here, contribute, in like manner, to the nourishment of the inhabitants; but what, it is said, they chiefly live upon, is a kind of nut like our filberts, which fall to the ground of themselves, and are to be found every where; every nut that so falls producing a new shrub in the succeeding year.

Fruit trees, shrubs, &c.

All the fruit trees common in Asia and in Africa prosper in Congo, and they even succeed there remarkably, attaining to such magnitude, that a single tree may be sufficient for the construction of a great number of houses or of canoes. Vegetation is here so rapid, that, if Lopez may be credited, he has seen a citron tree rising to a considerable height within four days from the time that he had planted it in the state of a seed. Among the fruit trees that are found here, there are mentioned besides, citrons, lemons, bananas, palm-trees; it is even alleged, that in the marshy grounds there grow sugar canes, of which the inhabitants make no use. There is also a kind of pepper, known by the name of malaguette, or manegette, which is an object of commerce with this people. Cassia, tamarinds, and other drugs that are held in esteem, grow here in abundance. It is said that the fruit trees found in these parts have in general been introduced by the Portuguese. Of palm-trees, which are exotic and brought from America, there occur no less than eight sorts, all excellent in their kinds, and which, in almost every part of them, are turned to useful account. The oil obtained from these trees is used instead of butter; with the moss that grows about the trunks, the rich commonly stuff their pillows, and the Giagas apply it to their wounds with good effect. With the leaves, the Moors cover their houses; and they draw from the trees by incision, a pleasant liquor like wine, which, however, turns sour within a few days. From the Congo palm-tree, so called because it thrives better in that country than any of the other sorts, there is obtained a liquor which is reckoned as valuable as the wine that is brought from Europe, though it is rather a kind of milk, sweet and agreeably tart, which will become sour in three or four days, and is so strong that a pint of it will produce intoxication. The fruit of this tree, not unlike a peeled chesnut in colour, taste, and substance, is, as has been remarked, the common food of the poorer class of the people. With the oil that is drawn from it, the natives dress their victuals, but the Europeans only burn it in their lamps. Of the shrubs of this country, may be mentioned the capano, or the fig of hell, from the nut of which is extracted an oil for the lamp, of which use is also made in the composition of ointments and plasters, while the leaves burnt to ashes, afford a good lye, with which the natives wash their bodies. Vines have been brought here from Candia, and they yield excellent grapes twice a-year. The manioc, which is used for making bread, is the same that is employed for the like purpose in Asia and America. The potatoes, and other roots of a like kind, yield a grateful nourishment. Wheat, it is said, is the only kind of vegetable produce that will not prosper here. It pushes forth, indeed, the straw and the ear; the former, we are told, even rising to such a height as to hide a man on horseback, while the latter continues empty, or without a grain in it fit for use. Father Labat, however, having, as he says, observed the same thing in some of the American islands, and having had the curiosity to examine those ears more carefully, found in them a few grains, which, having sowed afresh, they produced very long ears, full of large heavy grain; whence he concludes, that if the like experiment had been tried by the Portuguese in their African settlements, it might have been attended by a similar result. In the lowlands of Congo, the grass grows so high, rank, and thick, as to become one of the most dangerous receptacles for wild beasts, serpents, and venomous insects. Travelling through the country is thus rendered very dangerous, there being in the whole of it but few beaten roads, and the only passage being consequently over vast plains, where hazard is at once encountered from the destructive creatures by which these are frequented, and from the manifold diseases that are produced by the unwholesome dews with which the grass is covered during some part of the day. The flowers of these parts are exceedingly beautiful and numerous, almost every field and grove yielding, in this respect, a much nobler prospect than is presented by the European gardens, even after all the pains bestowed on their cultivation. These flowers are remarkable, not only for the prodigious variety of their colours, but for the vast quantity of heads which grow upon one stalk. The lilies which grow naturally in the fields, vallies, and woods, surpass those cultivated in Europe, not only by their extreme whiteness, but also by a most delightful fragrancy. The tulips that in like manner grow wild, have something surprisingly charming in the variety and combination of their colours, and their flowers grow 10 or 12 upon a stalk, which continue long in full bloom, and diffuse a very reviving and agreeable sweetness. The tuberoses, hyacinths, and other native flowers, are distinguished by similar properties, springing up in vast groupes of 100 or 200 from one root, some of them finely variegated, and all yielding an agreeable smell. The roses, jessamines, and other exotics brought from Europe or America, come up likewise in great perfection, and by due care may be long kept in that state. The fruit trees that have been introduced here, those that have been already mentioned, together with oranges, granates, cedars, and others, thrive, it is said, as well in this as in their native soil.

Wild animals.

The kingdom of Congo, like most other parts of Africa, breeds a prodigious variety of living creatures, both wild and tame. Those of the former sort are particularly numerous. The most remarkable of the animals in this class is the elephant, which is found chiefly in the province of Bamba, a province that abounds with woods, pasture, and plenty of water. They go commonly in troops of 100 or more; and some of them are of such a monstrous size, that the prints of their hoofs are said to measure from four to seven spans in diameter. They delight much in bathing themselves during the heat of the day. Lopez remarks, that they are of very gentle temper, and are much at ease as to

Congo. Wild animals.

their safety, relying upon their natural strength. They often approach the houses without doing any injury, and seldom pay any attention to the men that come in their way. Yet sometimes one of them has been seen raising a negro with his trunk, holding him suspended for some time, and then calmly letting him down again to the ground. The natives of this country have not the art of taming elephants: the only way, therefore, in which they can obtain profit from them is, by sending some of their bravest men to hunt them in the woods. The most common means through which this is done, is by digging deep pits in the ground, which are covered over with branches and leaves, in the same manner as is practised on like occasions in most parts of Asia. The business is generally attended with a good deal both of labour and of danger; but the esteem in which some of the exuviæ of the animal are held in the country is such, as to induce persons, from time to time, to undertake it. Besides elephants, this country abounds also in lions, which in like manner grow here to a vast size, tigers, wolves, and other beasts of prey. There is also a vast variety of monkeys of all sizes and shapes. The zebra of this country is a beautiful animal, which the natives hunt on account of its flesh, which they esteem a dainty food, and for its hide, which they send to Europe as a valuable commodity. A variety of buffaloes and wild asses occur here, and the dante seems to be an animal peculiar to this kingdom. It resembles an ox in shape and colour, but is not so large; its horns are like those of a he-goat, but very smooth and shining, and of a blackish hue. Its skin is commonly bought by the Portuguese, and sent into Germany to be tanned, and made into a kind of targets, which are known by the same name as the animal. Of the raw hides dried the natives make their shields, which are impenetrable to darts and arrows, and at the same time large enough to cover the whole body. They also make a variety of toys from its horns. The dante is a creature of great swiftness; and, when wounded, it will follow the scent of the gun-powder with such fury, that the huntsman finds it necessary, before he ventures to fire, to secure always a retreat in some tree, to which, in case of being unsuccessful in his aim, he may betake himself as speedily as possible. The wounded beast, finding its enemy out of its reach, stays for him at the foot of the tree, and will not stir from its place, while the hunter, taking advantage of this circumstance, dispatches it with repeated shots. Cameleons abound in Congo; and it has several sorts of wild rats, as the ninge, the niosse, and the marmoni, the furs of which surpass even those of the finest tigers, in the beauty, variety, and regularity of their streaks and spots. Another singular small quadruped is said to be found in this country, called the *entiengia*, which abides constantly in the trees, and is reported to die immediately upon setting its feet on the ground. Its skin is beautifully spotted, and is so much in esteem as an article of dress, that, in the country, none but the sovereign, and a few other privileged persons of the first rank, are permitted to wear it. It is at the same time looked upon as a proper present for the most considerable of the neighbouring princes, and as such is received by them with satisfaction.

The forests of Congo swarm with wild dogs, which like wolves prey upon the tame cattle, and are so fierce that they will attack armed men. The teeth of these animals are exceedingly keen and sharp. They never bark; but when famished, or in pursuit of their prey, they set up a dreadful howling. The different kinds of birds are found here that occur in other warm climates. Those called the birds of music are held in such esteem, that persons of the highest rank have, from time immemorial, taken pleasure in keeping them in cages and aviaries, for the sake of their surprising melody. There is a species of parrot, of which description of birds there is here a great variety, distinguished both by their size and colour. Others of the birds of the country the Congoese associate with their superstitions, a trait of character by which that people have been very greatly distinguished. What they esteem the most dreadful of the ominous kind of their birds, are crows, ravens, bats, and owls. Above all others, the great owl is looked on with the most terrible apprehension, and is known in the language of the country by the same name which is used to denote the devil. Both land and sea-fowls, in general, are here very numerous. The ostriches of this country are very large and beautiful, and their feathers, mixed with those of peacocks, which are no less numerous and beautiful, are used as ensigns or standards. They are also made into umbrellas. Turkies, geese, hens, and ducks, both wild and tame; likewise pheasants, pigeons, doves, woodcocks, and other smaller birds, abound in the country. Birds of prey, such as eagles, vultures, falcons of various sorts, sparrow-hawks, and others of a similar kind, occur in great numbers. Herons, bitterns, a bird in size and shape like a crane, one called by the Portuguese the pelican, of a large size and whitish colour, another called the fisher, which darts from a surprising height in the air on the fish, which he perceives in the sea or rivers, with other birds of the like voracious kinds, commonly abound in the marshes, lakes, and other waters.

Congo. Birds.

Tame animals.

Among the tame animals of Congo are enumerated oxen, sheep, hogs, horses, mules, and asses. The attention of the Portuguese has been in some degree directed to particular classes of these animals, especially to the cows, sheep, and goats, chiefly on account of their milk. They have not, however, learned the art of making butter or cheese.

Fish, serpents, &c.

Of fish, the sea adjoining to this country, and its rivers, afford great plenty and variety. It is likewise infested with various kinds of serpents, some of them of great magnitude, with rattle-snakes, vipers, and other venomous reptiles; also scorpions, and other venomous insects, both flying and creeping of several kinds. Lopez makes mention of a serpent of vast dimensions, and of a throat and belly so capacious, that it can swallow a stag entire. The negroes call it by a name, signifying in their language, 'the great water serpent.' It lives in rivers, but it seeks its prey on land. There it climbs up some tree, from which it watches the beasts. Having found an opportunity of attacking an animal, it twists itself around it, grasps it closely with its tail, and kills it with its bites. It then draws it into some retired place, where it devours it at ease, even to the skin, the bones, and the horns. Thus satisfied, it falls into so profound a sleep, that a child might then put it to death. It remains in this state for the space of five or six days; and it is commonly after it has been thus gorged, that it changes its skin. It extends itself on other occasions in the highways like a piece of wood, of which it has then all the appearance, and, with a swift movement, darts upon passengers, whether men or animals. The negroes prefer the flesh of this serpent even to that of chicken. The vipers of this country are several of them extremely poisonous, insomuch that their bite will occasion death within the space of 24 hours; but it is said, that the natives are acquainted with remedies that are sovereign for a cure, if seasonably applied. Of all the descriptions of creatures, however, from which danger is to be apprehended, none occur here more pernicious and fatal than the ants, of which there are enumerated not less than six several species of different colours and sizes, all of them formidable, on account of their prodigious numbers, and the mischief they do, not only to the fruits of the earth, but to men and beasts, whom, upon occasions, they will surround in vast multitudes, and devour to the very bone. They are not less injurious to clothes, linens, and such other stuffs, to which even the hardest wood is not found to afford an adequate defence against them. Yet, amidst this number and variety of destructive insects, there is found here also one species of a more friendly and profitable kind, viz. the industrious bee, which furnishes the inhabitants with honey and wax in such plenty, that there is scarcely a hollow tree, a cleft of a rock, or a chop in the earth, in which their combs are not deposited in great quantities.

Complexion, &c.

The inhabitants of Congo, their colour excepted, which is commonly black, though not unfrequently also of an olive hue, have a great resemblance to the Portuguese. Their hair is black and finely curled; some have it also of a dark sandy colour. Their eyes are for the most part of a fine lively black; in particular instances they are of a dark sea-colour. They have neither flat noses nor thick lips, like the Nubians and the most part of negroes. Their stature is mostly of the middle size. The general indolence of their disposition has been already noticed, which is such as to prevent them in a great measure from reaping the advantages easily within their reach from a soil which, if duly cultivated, would yield not only two, but sometimes even three, crops in the year. These people seem to consider it as unworthy of them to engage in any other exercises than those of dancing, leaping, shooting, and hunting, or on other occasions in smoking and more indolent recreations; whilst the laborious part of their household affairs, as also the operations of digging, sowing, reaping, and the like, are left to the conduct of their slaves,* or in other instances of their wives; and though they have plenty of domestic animals which might easily be trained to undergo the more laborious services, and it might be expected that the example of the Portuguese would incite them to endeavour to turn them in this manner to useful account, it does not appear that they have ever thought of taking the trouble which would be necessary for bringing them into a condition to yield them such valuable assistance. The backward state of things among this people seems not to be in any degree, or to be but little, the consequence of a want of a natural capacity; on the contrary, it is said, that with all their repugnance to any kind of labour in the least degree painful, they have even a most happy disposition for the practice of the mechanical arts. This is exemplified in the singular aptness that has been remarked among the inhabitants of the eastern limits of the kingdom, for the fabrication of different sorts of stuffs, such as velvets, satins, tissues, &c. The thread which they make use of for preparing these stuffs, they draw from the leaves of different trees, which they prevent from rising to too great a height for their purpose, by cutting them annually, and which, by means of frequent watering, they cause to send forth leaves more tender than they would naturally yield, and consequently better fitted for the formation of soft and smooth cloths. The same barks, moreover, as well as other parts of the trees, and indeed generally the different natural productions of their country, they shew not a little ingenuity in turning to various other useful purposes for the arts, or for their better accommodation in life. There is something, it may be added, to be observed here, that is akin to a division of labour, and the prosecution in different situations of different modes of labour respectively the best adapted to them. Thus the inhabitants of the cities are seen subsisting by the profits of their trade. Those who dwell in the country maintain themselves by the returns from agriculture, extremely simple and unimproved as this art indeed is among them, as well as by what they derive from their cattle. Those who border on the sea or on the great rivers, procure their maintenance by fishing.

General character.

The accounts given of the temper, affections, and disposition of mind and heart prevalent among the Congoese, are generally such as are indeed very little to their honour. They are said to be mistrustful, jealous, envious, treacherous, and much inclined to revenge. So devoid are they stated to be of natural affection, that a father will sell his son or daughter, or both, for a piece of cloth, a collar or girdle of coral or beads, a bottle of wine or brandy, or other matters of not greater intrinsic value, or capable of yielding a more permanent satisfaction. A man in this country, if a heathen, may take to himself as many wives as he pleases; or if his Christian profession should prevent this indulgence, he may have, what is the same thing in effect, as many concubines as he judges proper, and has over these such absolute and uncontrouled authority, that in whatever circumstances they may be, even in whatever stage of pregnancy, he may repudiate or even sell them at pleasure. But great as may in reality be the defects of their character, or how much room soever there may be for improvement, either in that or in any thing else relating to their condition, it has been remarked that there is perhaps hardly any nation on earth who have a higher opinion of themselves or of their country than this, or that are more hardened against all conviction to the contrary, from reason, experience, or any comparison of themselves with those whom they may have had opportunities of seeing from different parts of the world. It is a fundamental article of their belief, that the rest of the world was the work of angels, but that the kingdom of Congo, in its full and ancient extent, was the immediate production of the Supreme Architect himself, and of course has vast prerogatives and advantages over all others. When told of the magnificence of the European and Asiatic courts, their immense revenues, the grandeur of their palaces and other edifices, the richness and happiness of their subjects, the great progress they have made in arts and sciences, to which their own country is wholly a stranger, they coolly answer, that all this comes vastly short of the dignity and splendour of the kings and kingdom of Congo, and that there can be but one Congo in the world, to the

* The labour of slaves thus entering so much into the domestic economy of the Congoese, at the same time that the slaves themselves form the main branch of the traffic between this and other nations, they are naturally looked upon as a most valuable description of property, indeed as the chief property which a man can possess, or bequeath to his children or relations.

Congo.

happiness of whose monarch and people the rest of mankind were created to contribute, and to whose treasury the sea and rivers constantly bring their riches, whilst other princes and nations must condescend to dig through rocks and mountains in quest of the gold and silver which constitute their wealth, and as such are so generally and so supremely held in esteem amongst them. In conformity with these opinions, they imagine that the nations which come to traffic with them are forced upon that servile employment, from the badness and the poverty of their several countries, not incited to it by their luxury or avarice. For themselves, they consider it to be not a little to their honour, that they can with ease and contentment withstand the solicitations of the most pinching distress, rather than disgrace the nobleness of their blood by any kind of industry, which, however laudable and beneficial such industry may be, they are still disposed to regard as a lesser degree of slavery. They are not, however, equally fastidious in respect to begging or stealing, being indeed the most shameless and importunate beggars in the world, and such determined and outrageous robbers, that the only circumstance on account of which they deem any abstraction of property to be unlawful or scandalous, is its being committed in a private manner, and without the knowledge of the person wronged. It is esteemed a piece of bravery and gallantry to wrench any thing from another by violence; and this description of impudent rapacity is so common, not merely among the vulgar, but also among the great, that they make no scruple in their travels from place to place, to seize not only upon all the provisions they meet with in the towns and villages, but on whatever else comes in their way. In consequence of these violences, the poor people are eager, when apprehensive of such danger, to conceal, in the best manner they can, their few valuables, and esteem themselves happy if not compelled by a severe bastonading to discover them to their oppressors.

Population.

The population of Congo has been represented by some authors, who wrote either from mere conjecture, or from uncertain information, to be but inconsiderable. The missionaries we know, however, and the Portuguese who first visited this country, found it for the most part covered with towns and villages, which even swarmed with inhabitants. The metropolis, it is said, contained above 50,000 souls. The other cities were also filled with people. The provinces, if not equally populous, were yet far from being in this respect strikingly defective. The province of Bamba is even at present said to be able to raise to the amount of 200,000 fighting men; and its former population is said to have been double of what it now contains. The army of the King of Congo in 1665, is stated to have consisted of 900,000 fighting men, who were attended by an infinite number of women, children, and slaves.

Converts to Christianity.

The number of converts to Christianity, which a small number of Capuchin friars made among the more civilized of the people of this country, is affirmed to have amounted to 600,000. These accounts of the numbers of the Congoese will appear the more credible, when we consider the extreme fecundity of their women, the hardiness with which they bring up their children, and the stoutness and healthiness of their men. Consistent with these accounts is the statement we have received as to the numbers of slaves sold annually out of the country, which in ordinary years seldom fall short of 15,000 or 16,000.

The government of Congo is monarchical, and as despotic as any in Asia or Africa. The property of all the lands within their dominions is vested in the king, who parcels them out to individuals on condition of a certain tribute, and of the performance of particular services. Any failure in these respects, or any other neglect, is attended with ejection and deprivation; and the rigour and cruel extortion with which any demands that can be preferred on those grounds are too often enforced, are, as they might well be expected to be, the frequent occasions of revolt or of open rebellion. Even the princes of the blood are subject to the same laws in respect to property as others. Hence it is, that no person whatever, within the limits of this state, can bequeath a foot of land to his heirs; but when the first owners under the crown die, the lands which they held return to it again, whether they were in their own possession or in that of tenants, and it depends entirely on the prince whether then they shall be continued in the same, or disposed into other hands. The crown of this state is partly hereditary and partly elective. No candidate for it accordingly can be chosen, unless he be of the royal blood; and since the introduction of Christianity, it is in like manner necessary that he should be a Christian of the church of Rome. The whole process of the coronation of the prince, and his mode of living after his advancement to the throne, are attended with various circumstances of splendour and magnificence. It is but seldom that he goes abroad, and when he does so, he is attended by a numerous guard of Anseki and others of neighbouring nations, who are the most in his confidence, musicians, knights of the Holy Cross, an order which was instituted by the first Christian king of this country, and a number of officers richly accoutred. The respect which the Congoese pay to their sovereign, approaches even to idolatry. The palace in which he lodges is commodious, grand, and spacious; his court numerous and brilliant; and he has his seraglio, which is plentifully provided with concubines, who there indulge themselves in the most licentious gratifications, but are subject to be detained in it for the rest of their lives, and are placed under the controul of the single lawful wife, which, as to other Christians in this region, is alone allowed, even to the prince.

Congo. Government.

Revenue.

The royal revenue consists chiefly in the tribute that is obtained from several vassal princes, in free-will offerings, which are made in acknowledgement for the lands held under the sovereign, in the property of all the zimbis, or that description of shells which constitute the current coin of this and the neighbouring states; in mines of silver and gold, which, however, as serving comparatively little purpose here, are much neglected; and in the sums arising from the renewal of fiefs and investitures, from fines and confiscations. The prince has, moreover, a discretionary power of levying taxes on his subjects at pleasure.

Military force.

The standing forces of the Congoese monarchy are far from being numerous. They are at the same time neither well disciplined nor well clothed, nor well armed. Their mode of fighting is tumultuous and ferocious, and they give no quarter. Those that are taken alive being hurried to the sea-side, or to some inland market, are there sold for slaves to the Europeans.

Laws.

There are no written laws among the Congoese, but where favour or bribery do not interpose, custom and tradition serve them instead both of code and commentaries.

Administration of justice.

Every province has a chief justice for civil and criminal affairs, from whom an appeal lies to the king. Under him there are also inferior officers in every town and community. Treason, murder, and sorcery, are

Congo.

here deemed capital offences, of which the two first are punished by decollation, and the last by burning alive. The punishments of lesser offences are the bastinado, hanging, fines, and imprisonment.

Religion.

The religion of Congo was, and still is, in many parts of the country, a compound of the most degrading idolatry and superstition, joined with a complication of absurd and detestable rites, which have been invented by their gangas or priests, for the purpose of keeping the people in a state of the most abject subjection to their spiritual tyranny. There is acknowledged, indeed, one supreme being, called Nzambiamponga, believed to be all-powerful, and to whom is ascribed the creation of the country; but it is understood that the care and government of all sublunary things has been committed by him to a great variety of subordinate deities, who severally preside over their particular departments in nature. In conformity with such views, is the prodigious multiplication that is observed here of deities, idols, and altars, as also of gangas or priests, and of religious ceremonies. The forms under which those inferior deities are represented, vary with the inclination of the worshippers, and consist sometimes in resemblances of different living creatures, sometimes in representations of trees or plants of various kinds, and they sometimes assume the aspect of statues and images, often carved or painted with very considerable skill. The worship that is paid to these imaginary deities is expressed in genuflexions, fumigations, and such other unavailing services, with which the priests have influence and authority enough to join the making of offerings, nominally too in honour of the gods, but really and substantially calculated to benefit, nay even to enrich, those sacred persons themselves. Owing to this influence of the priesthood, not only have the endeavours of the kings of Congo for extirpating idolatry from their dominions been hitherto unsuccessful, but so much are both the most barbarous and the most refined classes of the people of this country, in all their transactions, under the impression of religious regards, that if a house is to be built or occupied, if the harvest is to be cut down, or any thing else, even of the most trifling nature, is to be undertaken, the favour of some deity or deities must ever be gained, through the instrumentality of their servants the gangas. Except in the case of the stated festivals of the new moons, it is the privilege, besides, of this body, to ascertain and fix the seasons generally of all religious observances, as well as the particular rites, sacrifices, and offerings, with which they are respectively to be accompanied; and, indeed, such is the opinion entertained of the highest dignity belonging to this order, that to the chalome, or chalombe, the person invested with it, the degree of reverence that is paid is such as borders on that which is thought due even to the gods themselves. The form of Christianity that was introduced into this country by the Portuguese preachers, after a footing had been obtained in it by that people, was, of course, that of the church of Rome. Even under that form, however, so much has it in later times been neglected, that little really now remains here of that religion except the bare name of Christian.

Concerning dying persons, the idea that is entertained among the Congoese is, that they are just passing from a wretched life into a state of tranquillity and happiness. Hence it is conceived that the best service that can be done to persons in such circumstances, is to accelerate their deliverance; a notion which, among the vulgar, leads sometimes to the barbarous practice of stopping their breath, or beating upon their breasts with violence, that they may the sooner enter into a state of felicity. In the inferior ranks of life, those who mourn for persons deceased shave their whole heads, and anoint themselves with oil, upon which they rub a quantity of earth, dust, and dried leaves, which give them a shocking appearance. Those of better condition shave only the upper part of their heads, which they bind with a list of cloth, linen, or leather, and confine themselves to the house for eight whole days. To shed tears on such an occasion is considered as a great crime, and is liable to punishment even if the culprit should be the king. Upon the death of the monarch, persons kept in pay for the purpose, go to all the public places in the cities to acquaint the people of the fact, by the mournful sound of their ivory cornets. Before the introduction of Christianity into the country, the funeral obsequies of such a personage were celebrated by various kinds of sacrifices and superstitious ceremonies, accompanied with music, howling, dancing, and feasting. These were continued for a week, and were resumed yearly on the anniversary of the king's demise. It was customary also to bury alive a certain number, not exceeding twelve, of the favourite concubines of the prince, or of the young ladies belonging to his court. In some of these respects an advantageous change has taken place in consequence of that event, though the effect has not been so complete as to put an end to the drunken revels which had been customary on such occasions.

The manner of interment for the princes and nobles, is to deposit the dead body in wainscotted vaults, hung with black; two of the old domestics of the parties deceased being destined alternately to guard the entrance, and to give them the benefit of their prayers. Other prayers are in like manner to be offered up on the anniversary of the decease, and on All-souls-day, at which times the graves are opened, and the hangings exchanged for new ones.

Amongst the Giagas, the most barbarous people of this kingdom, it is the custom to dance in a frantic manner about the graves of persons deceased, and to bring them food, drink, and other conveniences. The dances that are performed at the funerals of their great men last for eight days without intermission, upon which occasion there is always sacrificed a number of human victims.

Traffic.

The traffic of the Congoese with the Europeans consisted, for a long period, chiefly in slaves, of whom to the amount of 15 or 16,000 annually used to be carried off the country. In return, there were brought into it various products of Brasil, consisting of grains, fruits, plants, and the like, as also several articles of European manufacture, calculated to supply the necessities, to please the taste, or gratify the luxurious inclinations of the natives and unenlightened inhabitants. Among these are enumerated Turkey carpets, English cloth and the like, copper and brass vessels, ornaments and trinkets of various kinds, tobacco and spirituous liquors, light stuffs for clothing, and a great variety of tools and utensils.

State of the arts, &c.

The imperfect state of improvement in this country, is manifest alike in its general aspect, in the character of its manufactures, and in the nature of the accommodations to be obtained in it. The roads here are bad, and infested with banditti, and a variety of pernicious animals. Nothing almost in any of the de-

Congo ‖ Congreve.

partments of art is such as it might naturally be expected to be found among a people who had advanced far in the progress of civilization. Their houses are low ill-built huts, thatched with straw or fern, without windows, and which are not to be entered into even by the door, without stooping; they are besides so slightly built as to be liable to be blown away by a gust of wind. The furniture consists chiefly of a few ill-contrived instruments of agriculture, a hatchet, a cutlass, with the utensils for preparing or containing their provisions. The Congoese have amongst them a variety of rude musical instruments, such as those which they distinguish by the names of the usambi and the marimba, which are a very imperfect kind of stringed instruments; their ingambos or ingombos, a sort of drum made of the long hollow trunk of a tree, with a single skin stretched over one end of it, and which is beaten with the fists, or by sticks of heavy wood, while the other end of the instrument is left open, and the longa, which consists of one or two small belts. Their dancing has been characterised as merely a promiscuous collection of men and women, all striving who shall show the greatest agility and variety in their gambols, contortions, and indecent postures.

Musical instruments.

History.

Before the arrival of the Portuguese in Congo, its inhabitants were so totally unacquainted with letters that its prior history may be considered as perfectly fabulous. The tradition is, that its first prince was Luguen, the son of a neighbouring sovereign, who gradually united under his dominion the whole of the territory between the mouth of the Zair and the city of St Salvador, and whose legitimate successors have ever since maintained themselves in possession of the throne. This country was discovered by the Portuguese under the reign of John II. who employed Diego Cam, a person of enterprise and a famous navigator, in an expedition for extending the knowledge of the coasts of Ethiopia. The period when this took place was the year 1484. While engaged in this undertaking, Cam was accidentally carried into the Congoese country, and having been well received by the natives, was able to prevail on four of them to accompany him to Europe. Charmed with the accounts which they communicated to him respecting it, the king ordered Cam to return thither as speedily as possible, furnishing him with valuable presents for the sovereign and the court. He directed that this prince should be exhorted to become a convert to the worship of the only true God, and to permit the Christian religion to be propagated through his dominions. Cam, accordingly, having arrived again at Congo in the year 1485, was still very favourably received there, and an alliance having been established between the two crowns of Portugal and Congo, it has still continued to subsist, and was followed by at least a partial conversion of the country to the Christian faith. See Dapper's *Hist. d'Afrique; Mod. Univer. Hist.* vol. xiii. Peuchet's *Dictionnaire de la geographie commerçante; Bibliotheque universelle de Voyages*, &c. (K)

CONGRESS. See AMERICA.

CONGREVE, WILLIAM, a celebrated English dramatist, was descended from a family in Staffordshire, which traced its lineage beyond the Norman conquest. His father was an officer in the army, who was long stationed in Ireland; and in that kingdom young Congreve received so much of his early education, that he was believed by many to be an Irishman. Jacob, his biographer, had indeed told us, on the poet's own assurance, that he was born in England; but Dr Johnson thinks proper to commence the life of this great man, by suspecting him, in this instance, of telling a lie. His reasoning is thus conducted: "Nobody can live long without seeing lies of convenience, or vanity, uttered lightly; and once uttered, sullenly supported. Boileau told a lie to Louis XIV, which he never retracted, and therefore we may suspect that Congreve told Jacob a falsehood respecting the place of his birth." Mr Malone, however, has annihilated this *logical* suspicion, by producing the entry of Congreve's baptism, at Bardsea, near Leeds, in Yorkshire, in 1672. Every page of Johnson's biographies teems with those absurd aspersions on the memory of individuals, and the general character of human nature. Congreve received the first rudiments of his classical education at the high school of Kilkenny, where he is said to have discovered an early poetical vein, in a copy of verses which he wrote upon the death of his master's magpie. He went from thence to the university of Dublin, where, before he left it, at the age of sixteen, his biographer tells us, that he acquired a correct and critical acquaintance with the classics. This may seem almost incredible, yet the mind of Congreve seems to have been endowed with wonderful precocity; and, as we find him consulted by Dryden on his translation of Virgil, it is but fair to believe that he possessed considerable classical knowledge. That species of knowledge a man seldom improves after he leaves the university, and we may believe that Congreve imbibed it at a very early age. He was sent from Dublin to the Middle Temple in London, with a view of studying the law; but he proved one of the many deserters who enlist in that profession; and, at seventeen years of age, published a romance under a feigned name, entitled, *Love and Duty reconciled*. This is the romance which Dr Johnson says he would rather read than praise. We confess our inability to do either, as the romance is not among the books within our reach. The passage, however, in the preface that is quoted in the *Biographia Britannica*, bespeaks a mind wonderfully skilled, at the age of seventeen, in the technical views and language of criticism.

Congreve.

The first performance that brought him fairly before the public, appeared before he had completed his twenty-second year,—his comedy of *The Old Bachelor*. Dryden and Mainwaring corrected the piece, but the wit and genius were Congreve's. The stuff of it was said to be rich, but those experienced critics give it the cut of the fashion. *The Old Bachelor* was first acted in 1693, before a numerous and splendid audience, and received with thunders of applause: from that period Congreve mounted the throne of comic poetry, and during his life had no rival. Halifax immediately became his patron, and made him one of the commissioners for licensing coaches; and soon after gave him a place in the pipe-office, and another in the customs, worth £600 a-year. Next year he produced his *Double Dealer*, which was not received with equal kindness. Queen Mary honoured the representation of this and the former piece with her presence; and, at her death, which happened not long afterwards, Congreve displayed his gratitude in the pastoral strain, which was then absurdly customary on funeral occasions. In 1695, Betterton opened his new theatre in Portugal-row, Lincoln's-Inn-Fields; and our author supported him by his comedy of *Love for Love:* a comedy which, Dr Johnson remarks, has a nearer alliance to life, and exhibits more real manners, than any of the former. The character of the sailor, Dr

Congreve.

Johnson adds, though pleasant, is not natural; "we well remember," say the authors of the *Biographia Britannica*, in reply to this remark, "that forty years ago the character of Ben was not deemed unnatural. It was then a common tradition," they add, "that Congreve had resided six weeks at Portsmouth, in order to draw the character from living manners." Two years after, he exhibited, in his tragedy of *The Mourning Bride*, that he was qualified for either kind of dramatic poetry. It was well received. The author had not yet completed his twenty-eighth year. About this time he began his dispute with Collier, the puritan successor of Prynne, in hostility to the drama. Collier's attack upon the stage most probably checked its licentiousness: its contingent abuses the dramatic advocates could but lamely defend; but Congreve was sufficiently eloquent in maintaining the general moral utility of the drama. Congreve's last comedy was his *Way of the World*; which, though written with labour and thought, was received with so little favour, that, in disgust, he resolved no longer to commit his quiet or his fame to the caprices of an audience. A masque, entitled *The Judgment of Paris*, and *Semele*, an opera, the first of which only was represented, finishes the list of his works for the stage. From this time his life ceased to be public; he lived for himself and for his friends; engaged in no controversy, contending with no rival, and mixing neither in public animadversions nor personal criticisms. Though adhering to Halifax and the Whigs, he was so far respected by the Tories, that Lord Oxford refused to turn him out of his place; and when his friends returned to power, he was made secretary to the island of Jamaica; a place which, with that in the customs, raised his income to £1200 a-year. Every writer mentioned him with respect: Steele made him the patron of his *Miscellany*, and Pope inscribed to him his translation of the *Iliad*. Having risen, by a happy fortuity, above the griefs of an author's profession, he is said to have affected superiority to the profession itself. The anecdote, of his telling Voltaire, when he came to visit him, that he desired to be considered only as a gentleman, and not as an author, is one of the mortifying proofs, that the wisest may sometimes be foolish. The latter years of Congreve's life were clouded with sickness and infirmity. Cataracts in his eyes at length brought on total blindness; and repeated attacks of the gout prematurely undermined the vigour of his constitution. He sought relief from Bath; but the accident of being overturned in his carriage, left a durable pain in his side, and probably hastened his death, which took place in January 1729, in the sixtieth year of his age. He was interred with great funeral solemnity in Westminster Abbey, where a monument was erected to his memory by Henrietta, Duchess of Marlborough. To this lady, who is said to have had a most romantic regard for him, he left the bulk of his fortune, to the prejudice of relations, whose natural claims, and embarrassed circumstances, it was not to his credit that he neglected.

Congreve's occasional poems are so far beneath mediocrity, that we have reckoned it superfluous to enumerate either their names or their dates. As a writer of comedy, he stands, perhaps, at the head of that department of our drama. Not so much for humorous and natural, as for eccentric delineation of character, and, above all, for the perpetual corruscation of wit and repartee in his dialogue. His wit, indeed, flashes on us even to annoyance; and it is often difficult to distinguish the false wit of his fools, from that which is genuine in his sprightly personages. Mr Murphy, in his *Life of Garrick*, observes on this subject: The frequent surprises of allusion, and the quickness and vivacity of his turns of thought, which abound in Congreve, and which break out when you least expected them, as if a train of wit had been laid all around, put one in mind of those fireworks in a water-piece, which used formerly to be played off in Cupar's Gardens. No sooner one tube, charged with powder, raised itself in various forms and evolutions of fire, but instantly another and another was lighted up; and the pleasure of the spectators arose from seeing secret artificial mines blazing out of an element, in which such machinery could not be expected. To these exceptions we may, however, oppose the eulogistic part of Dr Johnson's character of him: "Congreve has merit of the highest kind: he is an original writer, who borrowed neither the models of his plot, nor the manner of his dialogue. He formed a peculiar idea of comic excellence, which he supposed to consist of gay remarks and unexpected answers; but that which he endeavoured, he seldom failed of performing. His scenes exhibit not much of humour, imagery, or passion; his personages are a kind of intellectual gladiators, every sentence is to ward or strike. But they are the works of a mind replete with images, and quick in combination. Unfortunate as he is in his miscellaneous poetry, he has some traits of genuine inspiration in *The Mourning Bride*, particularly in that proverbially celebrated passage, so frequently quoted:

> *Almeira.* It was a fancied noise—for all is hushed.
> *Leonora.* It bore the accent of a human voice.
> *Alm.* It was thy fear—or else some transient wind
> Whistling through hollows of this vaulted isle.
> We'll listen.——
> *Leon.* Hark !——
> *Alm.* No, all is hushed, and still as death.—'Tis dreadful.
> How reverend is the face of this tall pile,
> Whose ancient pillars rear their marble heads,
> To bear aloft its arched and pond'rous roof;
> By its own weight made stedfast and immoveable,
> Looking tranquillity! It strikes an awe
> And terror on my aching sight; the tombs
> And monumental caves of death look cold,
> And shoot a chillness to my trembling heart.
> Give me thy hand, and let me hear thy voice;
> Nay, quickly speak to me, and let me hear
> Thy voice—my own affrights me with its echoes.

(n)

Coni.

CONI, or CUNEO, from the Latin *cuneus*, a wedge, is a large fortified town of France, and capital of the department of Stura. It is situated at the confluence of the Stura and the Gezzo, upon a tongue of land in the form of a wedge. It stands upon a flat eminence, which commands the whole plain; and though it might still be assailed from the surrounding heights, yet these are generally taken possession of by the garrison when an attack is apprehended. The only buildings worthy of notice are several churches and convents situated without the town. The surrounding country, which is watered with four superb canals, produces grain of all kinds in abundance; and in a season of peace, Coni would be the centre of the commerce of all this part of Piedmont.

Coni derived its origin from a chapel dedicated to the Virgin, built upon the extremity of the tongue of land already mentioned. In 1120, the reputation of this chapel attracted crowds of pilgrims and devotees, and several houses were built for their accommodation. In 1127, an insurrection in the surrounding country contributed to its importance. The peasants of Caraglio and other places, fled from the tyranny of their lords, and built a small fortress in the spot where Coni now stands. In 1125, it was attacked in vain by Francis Stampa, the general of the Swiss army; in 1142, by the famous Claude Annebaud, who was afterwards admiral of France; and in 1557, by the Mareschal de Brissac. In 1796 it was taken by the French, and was added to the French empire in 1803. Population 16,500. See Deninas *Tableau Historique, Statistique et Morale de la Haute Italie*, p. 48, Paris, 1805; and Breton's *Voyage en Piemont*, p. 229, Paris, 1803. This last work contains a view of the town. (π)

CONIC SECTIONS.

Definition.

If a cone indefinitely extended be cut by a plane in any manner, the common section of its surface and the plane will be a geometrical line, which will be a curve in every case in which the plane does not pass through the vertex. The curves which may be formed in this way, although agreeing in some of their properties, will yet differ in others. There can only, however, be three varieties; an *Ellipse*, which is formed when the cutting plane passes in any direction across the cone; a *Parabola*, when it is parallel to one side of the cone; and an *Hyperbola*, when it has any other position. The cone may also be so cut that the section may be a *Circle*, but this curve may be considered as a kind of ellipse; so that, upon the whole, there are only three distinct curves. Their properties constitute a very extensive mathematical theory, a brief view of which is to form the subject of the present article. But before we proceed to the theory itself, it will be proper to give a short account of its origin.

History.

It is well known that almost all the discoveries and improvements in the mathematics have had their origin in the efforts which have been made to resolve problems. It cannot be doubted but that the attempts which have been made to square the circle, although abortive, have led to the discovery of many interesting properties of that figure: Another problem of far less difficulty, is commonly supposed to have called the attention of mathematicians to the conic sections, namely, the duplication of the cube, or, its equivalent, the finding of two mean proportionals between two given magnitudes.

When the ancient mathematicians had succeeded in making a figure similar to any given plane figure, and having to it a given ratio, they would be led by analogy to extend the problem to similar solids: and as these are to one another as the cubes of their corresponding lineal dimensions, the whole difficulty would be reduced to the making a cube that should have any given ratio to a given cube. The case when the ratio was that of 2 to 1 might be expected to be most easily resolved, and hence the duplication of the cube would occupy the attention of the first cultivators of geometry.

An ancient writer has, however, assigned a less natural origin to this problem. A pestilence is said to have ravaged Attica, and in the time of this calamity a deputation was sent to Delos to consult the oracle by what means the celestial anger might be assuaged. The god was very moderate in his demands; he only required that his altar, which was in the form of a cube, should be doubled. This was thought easy, and another of double the *lineal* dimensions was constructed. The true meaning of the god, however, was mistaken; for the new altar was evidently eight times greater than the old one: no wonder then that the plague raged as fiercely as ever. Upon a second application to the god, his order was exactly comprehended, and the affair was referred to Plato, in whose school geometry was at that time held in the highest estimation.

Plato.

There can be no doubt but that the abstract geometrical problem has been interwoven with the fable to give it a greater degree of interest; but it is certain, that this very problem was greatly agitated in the Platonic school; and, as from its nature, it cannot be resolved merely by straight lines and circles, the only lines at first admitted into geometry, it became necessary to inquire what other lines next in order of simplicity to these would afford a solution of this and similar problems, and this investigation would naturally lead to the conic sections.

Menæchmus.

It is impossible now to say exactly who had the merit of the first discovery. Some attribute it to Menæchmus, a disciple of Eudoxus, and a friend and contemporary of Plato. This opinion rests on his being the first on record that resolved the problem of finding two mean proportionals by the conic sections; and on some verses subjoined by Eratosthenes to his epistle to King Ptolemy, where they are called *the curves of Menæchmus.* However this may be, it is certain, that of eleven geometers, whose solutions of the problem have been recorded by Eutocius, two only have employed the conic sections, namely, Menæchmus and Apollonius Pergæus, the latter of whom lived at a later period than the former.

The interest which mankind in general take in the mathematical sciences, is but little in comparison to that which is excited by works of poetry, oratory, history, and the like, and hence it has happened that the writings of the ancients on these subjects have had a far better chance than their mathematical theories, of descending to the present times. However much we may regret the circumstance, it will not therefore appear wonderful that we now know nothing more than the names of the early cultivators of the conic sections: and of these Aristæus deserves to be particularly mentioned. Pappus of Alexandria informs us, in his Mathematical Collections, that this geometer composed five books *De Locis Solidis,* and as many on conic sections, all which are now entirely lost. The celebrated geometer Euclid is supposed to have been a disciple of Aristæus, at any rate he must have been his very particular friend. We learn from Pappus, that Euclid composed a treatise in four books on conic sections, but that also has been lost.

Conon.

Of several other geometers who appear to have cultivated this theory, we shall only mention Conon the friend of Archimedes; but he is better known as an astronomer than as a geometer.

Archimedes.

The writings of Archimedes shew, that before his time, considerable progress had been made in the discovery of the properties of the conic sections, as he refers to many of them incidentally, and speaks of others

Conic Sections.

as commonly known. Although he did not compose a complete treatise explaining the whole theory, yet he added a new branch to it, viz. that which treats of the areas of the sections, and the solids formed by their revolution about an axis: he demonstrated in two different ways, that the area of a parabola is two thirds of that of its circumscribing parallelogram; and this, for many ages, was the only true quadrature of a curvilineal space that was known. He also shewed what was the proportion of elliptic areas to their circumscribing circles, and of solids formed by the revolution of the different sections to their circumscribing cylinders. His various discoveries on this subject may be regarded as the sublime mathematics of that period.

Apollonius of Perga.

Apollonius of Perga may be reckoned the next in rank to Archimedes among the ancient geometers. He lived at a period about forty years later, that is, about the middle of the second century before the Christian era. He studied in the Alexandrian school under the successors of Euclid, and, besides writing treatises on the more abstruse branches of the mathematics cultivated at that time, he enriched the science by a work on conic sections, possessing a high degree of merit. It consisted of eight books. The first four is supposed to comprehend all that was known on the subject before his time, and the remaining books are reckoned to have contained his own discoveries. Several geometers of antiquity wrote commentaries on this work. Among the Greeks we find Pappus, who illustrated them by lemmas or preliminary propositions prefixed to each book. The learned Hypatia, the daughter of Theon, also wrote a commentary, which, however, is now lost, but another by Eutocius, on the first four books, is still extant. In later times, when the Arabians began to collect the fragments of knowledge that had escaped the wreck of the sciences in preceding ages of barbarism, the conics of Apollonius were one of the first works of which they undertook a translation. It was begun under the Caliph Almamon in the year 830 of the Christian era, and what had been prepared was revised and continued in the course of the same century by Thebit Ben-Cora. A new translation was made under the Caliph Abu-Calighiar, in 994: This version afterwards fell into the hands of the Italian geometer Borelli, as we shall presently have occasion to state. The Persian geometer and astronomer Nassir-Eddin, wrote notes on this work in the middle of the 13th century, and Abdolmelec of Scheeraz, another Persian, abridged it: all these versions in manuscript were at last found in Europe.

Hypatia.

Eutocius.

For a long time, however, only the first four books were known; and these in the Greek tongue, are the only part of the original work that has descended to modern times. When, or by what accident, the remainder was lost, is unknown. It existed, however, in the days of Pappus, who lived in the fourth century; for that geometer has, in his mathematical collections, given some account of each book, and of the *lemmata* employed in the demonstration of the propositions. Guided by these, mathematicians in modern times undertook the restoration of the books supposed to be lost; and in particular Maurolicus, a Sicilian geometer of the 17th century, composed a work, containing what he conceived to be the substance of the fifth and sixth books, which was published by Borelli in 1654. Viviani, a disciple of Galileo, and one of the most skilful geometers in Italy, had also begun a similar labour; and, while he proceeded slowly and in silence to prepare materials, the learned Golius returned from the East, bringing with him many Arabic manuscripts, among which were the first seven books of Apollonius' conics; but although this discovery was communicated to mathematicians as early as the year 1644, yet, as no translation appeared, the last four books were still regarded as lost. In the year 1658, Borelli discovered in the library of the Medici at Florence, an Arabic manuscript with an Italian title, stating it to consist of the eight books of Apollonius. This, by the liberality of the Duke of Tuscany, he was allowed to carry to Rome, and there, aided by Abraham Ecchellensis, a learned oriental scholar, he undertook a translation of it into Latin.

Viviani.

Meanwhile, Viviani was advised by his friends not to lose the fruit of his investigations, and accordingly, without being made acquainted with the contents of the books that had been found, he proceeded and published the result of his labours, in 1659. The translation made by Borelli, accompanied by learned notes, was published in 1661; and it is remarkable, that in the Arabic manuscript he had found, as well as in that of Golius, and in the abridged version of Abdolmelec which Ravius had brought from the East, and published in 1669, the eighth book is entirely wanting, so that it is now, in all probability, lost for ever. Dr Halley, however, attempted to restore it from the hints afforded by Pappus, and published the fruit of his researches along with the other seven books, and two books on the sections of cylinders and cones, written by Serenus, a geometer who lived in some of the early centuries of the Christian era. It is commonly supposed, that the restoration is so excellent, as to leave but little reason to regret the loss of the original.

The conics of Apollonius procured him the appellation of the *Great Geometer:* a character to which he appears to have been justly entitled, whether we consider the difficulty of the subjects on which he wrote, or the subtlety of his investigations and the skill and success with which he has conducted them. Among the improvements which he introduced into the mode of treating the subject, there is one particularly worthy of remark, because it is one of many instances in the history of science, of the slow progress of the human mind in passing from particular to more general truths. Before his time, the different curves were defined, by supposing right cones to be cut by planes perpendicular to their sides. By this method, three different cones were required to produce the three sections: a right angled cone for the parabola; an acute angled cone for the ellipse; and an obtuse angled cone for the hyperbola: But Apollonius shewed how all the three sections might be formed by any one cone, whether right or oblique.

In the early ages of science, the conic sections were cultivated merely as a geometrical theory, that might afford an agreeable subject of contemplation to the mind, but without a prospect of its ever being applicable to the explanation of the phenomena of nature. The discoveries of modern times, however, have greatly extended its utility, and rendered it by far the most interesting speculation in pure geometry. Galileo shewed, that the path of a body projected obliquely is a parabola, and Kepler discovered that the planetary orbits are ellipses; these facts alone were sufficient to enhance greatly the value of the theory of the conic sections; but the numerous discoveries of Newton that followed went much farther, and incorporated it with those of astronomy and the other branches of natural philosophy.

Conic Sections.

In explaining the nature and properties of geometrical figures, it becomes a question how they are to be defined. A figure may be defined from any one of its properties, which distinguishes it from all other figures of a different kind; but that ought to be chosen which is simple, which shews how the figure may be readily constructed, and which naturally leads to its other properties. The ancients defined the class of curves we are about to consider, by supposing a cone to be cut by a plane; and their example has been followed by several modern writers, who have, upon this principle, composed elaborate and valuable treatises. As the doctrine of solids is, however, a more intricate branch of geometry than that of plane figures, other modern writers, of whom Dr Wallis was the first, have thought it better to define the curves, by shewing how they may be described on a plane, without any reference to a cone; and treatises not less valuable, and (in our opinion) in some respects more simple, have been written on this plan. We propose to follow this second method, believing it to be the best adapted to our work.

If our system of GEOMETRY were written, we should refer to it as often as we had occasion to quote a proposition in the elements of geometry; as, however, from our mode of publication, that article is not yet ready, we shall, in the mean time, refer to the propositions in Euclid's *Elements of Geometry*, as contained in Mr Professor Playfair's edition: and in our article GEOMETRY give a table shewing to what proposition, there, each of Euclid's corresponds.

Catalogue of works on conic sections.

We shall conclude this Introduction with a catalogue of some of the more curious and valuable works on this branch of geometry.

Among the works of Archimedes which have been preserved, there is a treatise, On the Quadrature of the Parabola, and another On Conoids and Spheroids. See Barrow's edition, London, 1675; or Torelli's edition in Greek and Latin, Oxford, 1792; or Peyrard's French translation of Archimedes' works, Paris, 1808.

Apollonii Pergæi Conicorum libri octo, et Sereni Antissensis de Sectione Cylindri et Coni libri duo. This is Dr Halley's edition. The first four books, together with the Lemmata of Pappus, and the commentaries of Eutocius, have been published from Greek manuscripts, accompanied with a Latin translation; the 5th, 6th, and 7th books, which also contain the Lemmata, have been translated from Arabic into Latin; the eighth has been restored by Dr Halley. The books of Serenus are in Greek and Latin.

Collectiones Mathematicæ Pappi Alerandrini, lib. vii. Bononiæ, 1660. Here some account of Apollonius' Conics, and the Lemmata, is given.

Emendatio et Restitutio Conicorum Apollonii Pergæi, authore Francisco Maurolyco. Coloniæ, 1675.

Apollonii Pergæi Conicorum lib. v. vi. vii. *Paraphraste Abalphato Asphahnensi ex Arabico in Latinum* per Abraham Ecchellensem Maronitam redditi, cum notis J. Alfonsi Borelli. Florentini, 1661.

Apollonii Perg. Con. Sect. Lib. v. vi. vii. *in Grecia deperdita, jam vero ex Arabico MS. ante quadringentos annos elaborata opera subitanea Latinitate donati a* Christiano Ravio. Upsal, 1669.

De Maximis et Minimis, Geometrica Divinatione in Quintum Conicorum Apollonii Pergæi adhuc desideratum, autore Vincentio Viviani. Florence, 1659.

A Short Treatise on the Conic Sections, in which the three Curves are derived from a general description on a Plane, by the Rev. T. Newton. Cambridge, 1794.

A System of Conic Sections adapted to the Study of Natural Philosophy, by the Rev. D. M. Peacock. 1810.

A Compendious and Practical Treatise on the Construction, Properties, and Analogies of the Three Conic Sections, by the Rev. D. Bridge. 1811.

Essai de Geometrie Analytique applique aux Courbes et aux Surfaces du second ordre, par J. B. Biot. Paris, 1810.

A Treatise on Lines of the Second Order. This is part of a work entitled, *Geometry of Curve Lines,* by John Leslie, Professor of Mathematics in the University of Edinburgh.

There is much valuable matter relating to the conic sections in several works, which do not treat expressly on the subject. Particularly, in Newton's *Principia,* lib. i. The learned Jesuits, Le Seur and Jacquier, have given a concise treatise in their commentary on the work, at Prop. 8. lib. i. Maclaurin has treated of the conic sections in his *Geometria Organica,* sect. 1.; in his Fluxions, chap. xiv. and in sect. 2. of the Appendix to his Algebra. Euler has treated of them in his *Introductio in Analysin Infinitorum,* lib. ii. cap. 5. ; and De Moivre in his *Miscellanea Analytica,* lib. viii. cap. 2, The *Synopsis Palmariorum Matheseos* of Jones, also treats of the subject; but it would extend our catalogue too much to name all the writers who have improved the theory. The reader may see a copious list of them in *Bibliotheca Mathematica,* Auctore Fred. Guil. Aug. Murhard. Lipsæ, 1798.

The references in the following treatise are to be understood thus, (20. 1. E.) means the 20th Prop. of the 1st book of Euclid; (2. Cor. 20. 6. E.) means the 2d Cor. of the 20th Prop. of the 6th book; again, (5.) means the 5th prop. of the section in which the reference is found; (Cor. 1.) means the Cor. to the 1st Prop. (2. Cor. 3.) means the 2d Cor. to Prop. 3. and so on.

SECTION I.

Preliminary Propositions.

Prop. 1. *Theorem.*

Plate CCVII. Fig. 1, 2.

Let PEQ, *peq* be two parallel straight lines given by position, and F, *f* two given points in P*p*, a line perpendicular to them, which are equally distant from C the middle of that line, and let CA be a mean proportional between CF and CP; if D be such a point, that DF and DE, its distances from one of the points and the adjacent line, have to each other the given ratio of CF to CA, then also D*f* and D*e*, its distances from the other point and line, shall have to each other the same given ratio.

Join EF, *ef,* producing them until they meet in G; join GC, and draw GD, meeting F*f* in K.

The triangles EPF, *epf* are manifestly equal (34. and 4. of 1. E.) therefore the angles PFE, *pfe,* and consequently the angles GF*f*, G*f*F, GE*e*, G*e*E are equal (15. and 29. of 1. E.) hence GF = G*f*, and GE = G*e* (6. 1. E.), and GC is perpendicular to F*f* (4. 1. E.) Again the triangles EGD, FGK being similar, as also the triangles FEP, FGC, we have

ED : FK (: : EG : GF) : : CP : CF;
Now by hyp. DF : ED : : CF : CA,
therefore ex. æq. inv. DF : FK : : CP : CA, (23. 5. E.);
and since by hyp. ED : DF (: : CA : CF) : : CP : CA,
therefore, ED : DF : : DF : FK;

now the angles EDF, DFK are equal; (29. 1. E.) therefore the triangles EDF, DFK are equiangular (6. 6. E.) and hence the angles FED, KDF are equal, and (in both figures) the angle GED is equal to GDF: The triangles GED, GDF are therefore equiangular, (32. 1. E.) and GE : GD : : GD : GF, and hence also G*e* : GD : : GD : G*f*; now the angle at G being common to the triangles G*e*D, GD*f*, they are equiangular (6. 6. E.) hence the angle G*e*D is equal to GD*f*, and (in Fig. 2.) G*e*E is equal to *f*DK; but it has been shewn that GE*e* is equal to FDG, therefore, in Fig. 1. the angles FDK, *f*DK are equal, and in Fig. 2. the angle FDG is equal to *f*DK; hence, and because the lines E*e*, F*f* are similarly divided in D and K, in either case FD : *f*D (: : FK : *f*K) : : DE : D*e* (3. and A. 6. E. and art. Geometry) and by alter. FD : DE : : *f*D : D*e*.

Corollary. The points F, *f*, D, G are in the circumference of a circle. For it has been shewn, that the angle GDF is equal to GED, and therefore also to the angle G*f*F; hence (21. 3. E.) the points G, D, F, *f*, must be in the circumference of a circle.

Prop. II. *Problem.*

As in last proposition, let PQ, *p q* be two parallel straight lines given by position, and F, *f* two given points in P *p*, a line perpendicular to them, which are equally distant from C the middle of that line, and let CA be a mean proportional between CF and CP; it is required to find a point D such, that the ratio of its distances from each of the given points, and the line adjacent to that point, shall have to one another the given ratio of CF to CA. Plate CCVII. Fig. 1, 2.

Analysis. Let us suppose the problem resolved, or that D is found such, that DF and D*f* being joined, and ED*e* drawn perpendicular to PQ and *p q*, then DF : DE : : D*f*: D*e* : : CF : CA. Draw FE and *fe*, producing them until they meet in G. It follows from the corollary to last Prop. that the points F, *f*, D, G, are in the circumference of a circle; and as this position of the points appears to be all that is required, in order to resolve the problem, we have only to give the line E *e* such a position, that a circle described about the triangle FG*f* may meet it in a point D. Now, there will be two cases of the problem.

Case 1. When the points F, *f* lie between the lines PQ, *p q*, as in Fig. 1.

Case 2. When the lines PQ, *p q*, pass between the points F, *f*, as in Fig. 2.

In the first case, (Fig. 1.) join GC, producing it to meet the circle in L, and E *e* in H, and join FL; then by reasoning, as in Prop. 1. it will appear that the line GCL is perpendicular to F*f*, and therefore is the diameter of the circle (1.3.E.); and consequently, GFL is a right angle, (31.3.E.) and the triangle EPF, which

2

Conic Sections.

PLATE CCVII. Fig. 1, 2.

is similar to GCF, (29. and 15. 1. E.) is also similar to FCL, (8. 6. E.) Therefore, LC : CF : : FP : PE or CH, hence, LC.CH=CF.FP, (16. 6. E.); but since the circle must meet the line ED e, CH cannot exceed LC; and therefore CH^2 cannot exceed LC.CH, although it may be either equal to it or less. Hence, CH^2 may be equal to any space that does not exceed CF.FP; and the point H may be on either side of F f.

In the second case, (Fig. 2.) from the position of the points F, f, in respect of the lines PQ, $p\,q$, the point H necessarily falls between C and G, and therefore is always within the circle; hence it may be any where in a line perpendicular to F f at C.

Composition. In each case, draw a line to bisect F f at right angles in C, and, in Case 1. (Fig. 1.) take CB and C b in that line, each equal to a mean proportional between CF and FP, and take H any where in B b; but, in Case 2. (Fig. 2.) H may be taken any where in the line which bisects F f at right angles in C. In each case, through H draw a line parallel to F f, meeting PQ and $p\,q$ in E and e, and draw the lines EFG, $e\,f$G, meeting in G, which will be a point in the perpendicular to F f at C, (as shewn in the first proposition.) Describe, next, a circle about the triangle FG f, and, in Case 1. let this circle meet CB in L, (Fig. 1.) then if FL be drawn, it may be shewn, as in the Analysis, that LC.CH=CF.FP=CB^2 (by construction); therefore B falls between H and L, and so CL is not less than CH; but, in Case 2. (Fig. 2.) the point H falls always between C and G; therefore, in either case, the circle must meet the line E e, Fig. 1. or that line produced, (Fig. 2.); let D be either of the points of section. Draw DF, D f, and the problem is constructed.

Draw DG meeting F f in K; and because the chords FG, fG, and consequently the arcs FG, fG, are equal, in Fig. 1. the angles GDF, GD f are equal, (27. 3. E.); and, in Fig. 2. the angle GDF is equal to GF f, (27. 3. E.); but in Fig. 2. KD f is also equal to GF f, (13. 1. and 22.3.E.); and therefore GDF=KD f: hence in each case GK makes equal angles with DF, D f; and therefore DF : D f : : KF : K f, (3. and A.6 E.) But the lines E e, F f being similarly divided at D and K, (Geometry,) KF : K f : : DE : De, therefore DF : D f : : DE : D e.

Again, the angle GED being equal to GF f, (29. 1. E.) or G fF, that is to GDF, (21. 3. E.) the angles FED, KDF are equal, now the angles FDE, DFK are equal, (29. 1. E.); therefore the triangles EDF, DFK are equiangular, (32. 1. E.) and

ED : DF : : DF : FK,
hence ED : FK : : ED^2 : DF^2 (2 Cor. 20.6.E.)
but ED : FK : : EG : GF : : PC : CF (4. & 2. 6. E.)
and PC : CF : : CA^2 : CF^2 (2 Cor. 20. 6. E.)
therefore, CA^2 : CF^2 : : ED^2 : DF^2
and CA : CF : : ED : DF : : e D : D f.

Cor. 1. This problem is *indeterminate*, or admits of an indefinite number of solutions. For it appears that, in Case 1. (Fig. 1.) the line ED e, in which the point D is always situated, may have any position between the two limits B, b; and that in Case 2. (Fig. 2.) it may have any position whatever, provided, however, that in each case it be parallel to F f.

Cor. 2. For any one position of the line ED e, in which it does not pass through B or b, in Case 1, there are two points D, D′, and no more: because a circle can cut a straight line only in two points. When the line ED e passes through B or b, in Case 1. there is only one point.

Scholium.

Conic Sections. PLATE CCVII. Fig. 1, 2.

As it appears from the construction of the problem, that in both cases, there are innumerable points D, having the property required, viz. two in any line meeting B b between the points B, b, and parallel to F f, (Fig. 1.) or in any line whatever parallel to F f, (Fig. 2.) these points must all lie in some line XDY of a determinate kind, which will be what is called the *locus* of the point that satisfies the conditions of the problem, and the properties of which may be made the subject of a geometrical theory.

The figure of the *locus* depends greatly upon the position of the points F, f in respect of the lines PQ, $p\,q$, or (which comes to the same thing,) the kind of ratio that FD has to DE, and fD to D e. For we have seen in Fig. 1. where CF is less than CA, and consequently the ratio of CF to CA, or of FD to DE is a ratio of minority, that the *locus* extends only to a limited distance on each side of the line F f: and that in Fig. 2. where CF is greater than CA, and the ratio FD to DE is a ratio of majority, the locus recedes to an indefinite distance on each side of F f. This peculiarity of figure shews that there are two distinct species of lines, one is the locus of D when FD has to DE a ratio of minority, and another, when it has a ratio of majority.

Moreover, as in each case, we may suppose the ratio to approach as near to that of equality as we please, there must be an intermediate species, which may be regarded as the limit to either of the other two. Now, since (Fig. 1. and 2.) F f : P p (: : CF : CP : : CF^2 : CA^2) : : FD^2 : DE^2; when this last ratio approaches to that of equality, the lines F f, P p must also approach to equality; so that if we suppose the point F and line PQ to be given by position, the other point f and line $p\,q$ will recede from them continually; and the ratio of FD to DE becoming absolutely that of equality, the point f and line $p\,q$ will have gone off to an infinite distance, or, in other words, they will no longer exist.

These three species of lines were denominated Conic Sections by the ancient geometers, because they may also be defined by the section of a cone and plane.

They gave the name Ellipse to the line which is the *locus* of D, when FD has to DE a ratio of minority; they called it an Hyperbola, when the ratio was that of majority; and a Parabola, in the case of a ratio of equality. We shall now explain the principal properties of these lines in the following Sections.

SECTION II.

Of the Ellipse.

Definitions.

1. Let PEQ, $p\,e\,q$ be two parallel straight lines given by position, and F, f two given points between these lines in P p a line perpendicular to them, equally distant from C the middle of that line; and in P p, let CA, C a be taken in contrary directions, each equal to a mean proportional between CF and CP, then, if a point D be supposed to move in the plane of the lines, in such a manner, that DF, its distance from one of the given points, has to DE, its distance from the given line adjacent to that point, the given ratio of CF to CA, and consequently (Sect. I. prop. 1.) so that D f, its distance from the other point, has to D e, its distance from the other line, the same given ratio; the point D will describe a curve line called an *ellipse*. PLATE CCVII. Fig. 3.

2. Each of the lines PQ, $p\,q$ is called a *directrix*.

3. Each of the points F, *f* is called a *focus*.

4. The given ratio of CF to CA is called the *determining ratio*.

5. The point C is called the *centre* of the ellipse.

Cor. to Def. 1. The ellipse passes through the points A, *a*; and these are the only points in which it can meet the line A*a*: For, since CA : CP : : CF : CA, therefore, CA—CF : CP—CA : : CA : CP : : CF : CA, (19. 5. E.), that is, FA : AP : : CF : CA. Also, since C*a* : CP : : CF : C*a*, therefore C*a*+CF : CP+C*a* : : CF : C*a*; that is, F*a* : *a*P : : CF : C*a* or CA. The truth of the second part of the corollary is evident from the way in which a line is divided into parts having a given ratio.

Cor to Def. 1, 3, 4. If a straight line MF*m* be drawn through F either of the foci, at right angles at A*a*, and FM and F*m* be each taken to FP in the determining ratio, the points M, *m* will be in the ellipse; and these are the only points in which the line M*m* can meet the curve.

Def. 6. The straight line A*a* is called the *Transverse Axis*.

7. The points A, *a*, the extremities of the transverse axis, are named the *Vertices*.

8. The distance of either focus from the centre is called the *Eccentricity*.

Cor. to Def. 2, 3, 4, 6. The distance between the foci has to the transverse axis, also the transverse axis has to the distance between the directrices, the determining ratio.

Prop. I.

Fig. 3. The sum of two straight lines drawn from any point D in the ellipse to the foci, is equal to the transverse axis.

For ED : DF : : P*p* : A*a*,
and *e*D : D*f* : : P*p* : A*a*,
therefore ED+*e*D : DF+D*f* : : P*p* : A*a*:
But ED+*e*D=P*p*, therefore DF+D*f*=A*a*.

Scholium.

Some writers on conic sections employ this property in defining the ellipse thus: Let F and *f* be two given points in a plane, and let a point D move on that plane so, that the sum of its distances from the given points may be equal to a given line; then the path of the moving point will be an ellipse.

The property in question affords also an easy mechanical description of the curve: Let the extremities of a string, equal in length to the transverse axis, be fixed at the foci F, *f*, and let the string be stretched into the straight lines DF, D*f* by a pin held at D, while the point of the pin is moved upon the plane, then it is manifest that the point will trace an ellipse.

Prop. II.

Fig. 4. Let FM, a perpendicular to the transverse axis at either focus, terminate in the ellipse at M, and let a circle be described on F as a centre, with FM as a radius, then if, from any point D in the curve, a line DF be drawn to the focus, and produced to meet the circle in I, and IN be drawn perpendicular to the axis, the rectangle contained by the variable lines PN, FD is equal to the constant rectangle PF.FM.

Draw DE perpendicular to the directrix, and join EF and PI: Then, because FM or FI : FP : : FD : DE (Cor. to Def. 1, 3, 4), and the angles EDF, PFI are equal (29. 1. E.), the triangles EDF, PFI are similar (6. 6. E.), therefore FE is parallel to PI (28. 1. E.): Hence the angles EFP, IPN are equal, and the angles at P and N being right angles, the triangles EPF, PNI are also equiangular, and FD : FI (: : FE : PI) : : FP : PN (4. 6. E.), therefore FD.PN= FP.FI=FP.FM (16. 6. E.)

Cor. From this proposition we may determine D, the point in which a line FD given by position, passing through the focus meets the curve, viz. by taking a point I in DF produced, such that PF may be to FI in the determining ratio, and drawing IN perpendicular to PF, and taking FD a fourth proportional to PN, PF, and IF.

Scholium.

From this proposition we may get a correct notion of the figure of the ellipse, by considering the changes which take place in the magnitude of the line FD, while the angle PFD gradually changes, increasing from nothing to two right angles. For let us first suppose the line FD to come to the position FA, then the point N will recede to L, the extremity of the diameter of the circle farthest from P; and as in every position of the line FD, the rectangle PN.FD is equal to the constant rectangle PF.FM, when the point N is at L, so that PN is the greatest possible, then FD will be the least possible. Suppose, now, the line FD to depart from the position FA, and to revolve about F; then, as the angle PFD increases, the point N will approach to L′, the extremity of the diameter nearest to P, arriving at it when the revolving line coincides with P*a*: the line PN will now be the least, and (because the rectangle PN.FD is equal to the constant rectangle PF.FM) the line FD will be the greatest possible: and as PN has had all degrees of magnitude between the two limits PL and PL′, so FD will have had all degrees of magnitude between FA and F*a*.

If the line FD be supposed to continue its revolution, and to move to the other side of the axis A*a*, it will decrease exactly as it had increased, until at last, after a complete revolution, it returns to its least magnitude FA. Upon the whole, we may draw the following conclusions:

1. The ellipse is a continuous line, surrounding a space in which the foci and centre are situated.

2. Of all the lines which can be drawn from either focus to the curve, the shortest is the part of the conjugate axis between the focus and nearest vertex, and the greatest is the remainder of that axis; and of the rest, that which is nearer to the least is less than that more remote.

3. Lines drawn from either focus to the curve, making equal angles with the axis, and lying on opposite sides of it, are equal to one another.

Definition 8.

A straight line B*b* passing through the centre, at right angles to the transverse axis, and terminating in the curve, is named the *Conjugate Axis*. Fig. 3.

Prop. III.

The distance of either extremity of the conjugate axis from either focus is equal to the semitransverse axis.

For, draw BF to either of the foci, and BG perpendicular to the directrix. Then FB : BG : : CA : CP or BG, therefore FB=CA. Fig. 3.

Cor. 1. The conjugate axis is bisected at the centre, for, join F*b*; and, because FB=F*b*, the angle FBC is equal to F*b*C (5. 1. E.), and the angles at C being right angles, and the side FC being common to the triangles

Ellipse.

FBC, FbC, they are in all respects equal (26. 1. E.), hence $BC=bC$.

Cor. 2. The square of the semiconjugate axis is equal to the rectangle contained by the parts into which the transverse is divided at either focus. For $AC^2=AF.Fa+FC^2$ (5. 2. E.) and $FB^2=FC^2+CB^2$ (47. 1. E), therefore since $AC^2=FB^2$, it follows that $AF.Fa=CB^2$.

Cor. 3. The square of the semiconjugate axis is also equal to the rectangle contained by the eccentricity and the distance of either focus from its directrix. For since PC : CA : : CA : CF (Def. 1.) $PC.CF=CA^2$ (17. 6. E.) now $PC.CF=PF.FC+CF^2$ (3. 2. E.), and $CA^2=BF^2=BC^2+CF^2$; therefore $PF.FC=BC^2$.

Definition 10.

A straight line which meets an ellipse, and being produced does not cut it, is said to *touch* the ellipse, and is called a *Tangent.*

Prop. IV. *Problem.*

Having given the transverse axis and a focus, and consequently its directrix, to find the points in which a straight line given by position perpendicular to the axis, meets the ellipse.

Fig. 5. Let Aa be the transverse axis, F the focus, PQ the directrix, and Ll the line given by position, which meets the axis in G: let FM perpendicular to the axis at F meet the curve in M: draw PM meeting the line given by position in L: describe a circle on F as a centre, with GL as a radius, meeting Ll in D, and d, and these will be two points in the ellipse.

For, join FD, Fd, and draw DE, de perpendicular to the directrix. Then the triangles PGL, PFM are manifestly similar, therefore GL : GP : : FM : FP; or, since ED and ed are each equal to FG (34. 1. E.), FD : DE, also Fd : de : : FM : FP, that is in the determining ratio (Cor. to Def. 1, 3, 4.); therefore D and d are points in the ellipse.

It appears that the problem can be resolved only when Ll has such a position that GL is not less than FG. To determine the limits within which this happens, draw AH, ah perpendicular to the axis, meeting PL in H and h; and join FH, Fh; then, by similar triangles, PF : FM : : PA : AH : : Pa : ah, but PF : FM : : PA : AF : : Pa : aF (Cor. to Def. 1, 3, 4.), therefore, $AH=AF$, and $ah=aF$. Now, let GL meet either of the lines Fh, FH in N, then $GN=GF$, and G being any point between A and a, GN, or GF, is less than GL; but at the points A, a, GN is equal to GL, and at any point in Aa produced, GN is greater than GL; therefore the problem will be possible only when the point G is any where in the line Aa.

Cor. 1. Every straight line perpendicular to the transverse axis between its extremities, meets the curve in two points, and no more; also at the extremities it meets the curve in one point only; and beyond the extremities it falls entirely without the curve.

Cor. 2. In the ellipse, every straight line perpendicular to the transverse axis, and terminating in the curve, is bisected by the axis.

Cor. 3. A perpendicular to the transverse axis at either of its extremities is a tangent to the curve.

Cor. 4. The transverse divides the ellipse into parts exactly alike.

Prop. V. *Problem.*

The transverse axis, and a focus, and consequently its directrix, being given, to find the points in which a straight line given by position parallel to the axis meets the curve.

Fig. 6. Let EH, the line given by position, meet the directrix in E, and the conjugate axis Bb, in H; draw EF through the focus, to meet HG in G: On G as a centre, with a radius equal to a mean proportional between GF and GE describe a circle, meeting EH in D and d, and these will be points in the ellipse. For, join DF, dF, DG, dG, and because EG : GD : : GD : GF, and the angle at G, is common to the triangles EGD, DGF; these triangles are equiangular (6. 6. E.), and ED : DF : : EG : GD; therefore $ED^2 : DF^2 : : EG^2 : GD^2$ (22. 6. E.); but $EG^2 : GD^2$: : EG : GF (2. Cor. 20. 6. E.) : : PC : CF (2. 6. E.), and $PC : CF : : AC^2 : CF^2$ (2. Cor. 20. 6. E.) therefore $ED^2 : DF^2 : : AC^2 : CF^2$, and ED : DF : : AC : CF; hence D is a point in the ellipse, and in the same manner it may be shewn that d is a point in the ellipse.

It appears that this problem can be resolved only when GH does not exceed GD, a mean proportional between EG and GF, and this circumstance restricts the position of the line given by position within certain limits. To determine these, draw FL perpendicular to FG, to meet GH in L. Then the triangles GHE, GFL will be equiangular (32. 1. E.), therefore EG : GH : : GL : GF; hence $GH.GL=EG.GF$ (16. 6. E.)$=GD^2$ (by construction): and as GH^2 may have any magnitude that does not exceed GD^2, therefore CH^2 must not exceed GH GL, that is, GH must not exceed GL, or CH must not exceed CL, or CH^2 must not exceed CH.CL; but the triangles EPF, FCL being similar, because each is similar to GCF (29. 1. and 8. 6. E.) LC : CF : : FP : PE or CH, therefore $CH.CL=FP.FC$ (16. 6. E.)$=CB^2$ (3. Cor. 3.), therefore CH^2 must not exceed CB^2, and CH may have any magnitude not greater than CB, the transverse axis.

Cor. 1. If an indefinite straight line meets the conjugate axis at right angles between its extremities, it cuts the curve in two points, and no more; if it pass through either extremity, it meets the curve in one point only; and if it meets the conjugate axis produced, it falls entirely without the curve.

Cor. 2. Every straight line perpendicular to the conjugate axis, and terminating in the ellipse, is bisected by that axis.

Cor. 3. A perpendicular to the conjugate axis at either of its extremities, is a tangent to the ellipse.

Cor. 4. The ellipse is divided into two parts exactly alike by the conjugate axis.

Prop. VI.

Fig. 7. If from any point Q in the directrix, a straight line be drawn to meet the ellipse in D, and LFl, a parallel to the directrix, passing through the focus, in H; and if another straight line be drawn to D through F, and a perpendicular QK be drawn to FD; the lines FH, QK have to each other the determining ratio.

Draw DE perpendicular to the directrix, and let DF meet it in I. The triangles DHF, DQI are equiangular (29. 1. E.), and the triangles QIK, DIE are also equiangular, for the angles at K and E are right angles, and the angle at I is common; therefore FH : FD (: : QI : ID) : : QK : DE (4. 6. E.), and by alternation, FH : QK : : FD : DE, that is in the determining ratio.

Cor. 1. If a straight line meet the directrix in Q, and the parallel Ll in H; and if a straight line KFD pass through the focus, and FH have to KQ, (the distance of KF from the point Q), the determining ratio, the lines QH, KFD will meet at a point D in the ellipse: For then, FD : DE : : FH : QK, that is in the determining ratio.

Cor. 2. If QF be drawn to the focus, and in the line LFl parallel to the directrix, there be taken FL, Fl in contrary directions, and each to QF in the determining ratio, then every straight line drawn from Q to meet the ellipse, will either pass between the points L, l, or through these points. For since by hypothesis FQ : FL : : KQ : FH; and since KQ cannot exceed FQ, therefore FH cannot exceed FL.

Cor. 3. Any straight line drawn from Q to cut the line Ll beyond the limits L, l falls without the ellipse.

Prop. VII. *Problem.*

Having given a focus, its directrix, and the determining ratio, to find the points in which a straight line given by position, and not parallel to the directrix, meets the ellipse.

Fig. 8. Case 1. Let XY, the line given by position, pass through F the focus; draw FQ perpendicular to XY, meeting the directrix in Q; and in LFl, a line passing through the focus parallel to the directrix, take FL and Fl, each to KQ in the determining ratio; and because FL and Fl are each less than FQ, the angles FQL, FQl are not right angles (Geometry), therefore the lines QL, Ql will always meet the line XY in two points D, d, which will be points in the ellipse, as is evident from Cor. 1. Prop. 6.

Fig. 9. Case 2. Next, let the line given by position meet the directrix in Q, and Ll the line passing through the focus parallel to the directrix in H; so that QF being drawn to the focus, and FL and Fl taken each to FQ in the determining ratio, the point H falls between the focus, and either of the points L, l. In QF take QN, so that FH may have to QN the determining ratio, then FH : QN : : FL : QF; but FH is less than FL, therefore QN is less than QF: On Q as a centre, with QN as a radius, describe a circle, and draw FK, Fk tangents to it, also draw FO perpendicular to QH; then, as FH is less than KQ, FO will be much less than KQ, or kQ; therefore the lines KF, kF cannot be parallel to QO, and they must, if produced, meet it in two points D, d, which will be points in the ellipse, as is evident from Cor. 1. Prop. 6.

Fig. 9. Case 3. Lastly, let the line given by position meet the directrix in Q (Fig. 9.), and be so situated, that QF being drawn to the focus, and FL and Fl each taken to QF in the determining ratio, the line passes through L, either of the extremities of the line Ll; then it will appear, as in the first case, that FQL cannot be a right angle; therefore, FD′ being drawn perpendicular to FQ, will meet QL in D′, a point in the ellipse, Cor. 1. Prop. 6.

Cor. 1. The points L, l being determined, as in the second and third cases, any straight line drawn from Q, to pass between them, will meet the ellipse in two points, and no more: For it has been shewn, that the tangents FK, Fk must always meet the line given by position in two points D, d; and as these are evidently the only lines which can be drawn through F, so that FH may have to QK, Qk, (their distances from Q) the determining ratio, there can be no more than two intersections of the line QH and the ellipse.

Cor. 2. If from D, d, the intersections of a straight line and an ellipse, straight lines DF, dF be drawn to a focus, these make equal angles with QFR, a line drawn through the focus from Q the point in which the intersecting line meets the directrix. For the angles dFQ is equal to KFQ or DFR.

Cor. 3. The points L, l being determined as in the proposition, a straight line drawn from Q through either of these points is a tangent to the ellipse. For in this case only one line FD′ can be drawn through F, so that FL has to FQ its distance from Q, the determining ratio, and it appears that the ellipse lies wholly on one side of FL, (Cor. 3. 6.) therefore FL is a tangent. (Def. 10.)

Cor. 4. If a straight line meet an ellipse, it will either touch it, or cut it in two points, and in no more. This follows from the Prop. and Prop. 4. and 5.

Cor. 5. If two straight lines FD, FQ (Fig. 10.) which contain a right angle at the focus, meet the curve and the directrix in D and Q; the straight line DQ, joining these points, is a tangent to the ellipse at D; and only one tangent can be drawn to the curve at that point. It is evident from the construction of Case 3. and Cor. 3. that the line DQ is a tangent. To prove that there is no other tangent at D, draw any other line DQ′ through D; if this line be parallel to the directrix, it will cut the curve (Prop. 4.) but if it be not parallel, let it meet the directrix in Q′, and FH a parallel to the directrix passing through the focus in H. Draw Q′K perpendicular to FD; join Q′F; and take FL to Q′F in the determining ratio; and because D is in the ellipse, FH has to Q′K the determining ratio (6.) therefore FQ′ : FL : : Q′K : FH, but FQ′ is greater than Q′K, therefore FL is greater than FH; hence the line Q′H must meet the ellipse in two points by Cor. 1. of this proposition. Fig. 10.

Cor. 6. Tangents DQ, dQ (fig. 8.) at the extremities of any focal chord Dd, and a perpendicular FQ to that chord at the focus, meet at a point Q in the directrix. Fig. 11.

Prop. VIII.

A tangent to the ellipse makes equal angles with straight lines drawn from the point of contact to the foci.

If the tangent be at either extremity of the tranverse or conjugate axis, the truth of the proposition is manifest; in any other case let it touch the curve at D, and meet the directrices in Q and q; draw DF, Df to the foci, and EDe perpendicular to the directrices. The triangles DEQ, Deq, are manifestly equiangular, therefore DQ : DE : : Dq : De (4. 6. E.) but DE : DF : : De : Df (Def. 1.) therefore ex. æq. DQ : DF : : Dq : Df (22. 5. E.) hence it appears that the triangles DFQ, Dfq, which have the angles at F and f right angles, (Cor. 5. 7.) have the sides about one of the remaining angles in each proportionals, therefore they are equiangular, (7. 6. E) and have the angles QDF, qDf equal.

Definition 11.

A straight line passing through the centre, and terminating both ways in the ellipse, is called a *diameter*, and the points in which it meets the ellipse are called its *vertices*.

Prop. IX.

Every diameter is bisected at the centre.

From D, any point in the ellipse, draw the chord DHd' perpendicular to the conjugate axis at H, and the chord $d'hd$ perpendicular to the transverse axis at h, and join Hh, DC, dC: Then DH = Hd', (2. Cor. 5.) = Ch (34. 1. E.) and HC = $d'h$ = hd (2. Cor. 4.) Fig. 12.

Ellipse. hence the figures DH*h*C, H C *d h* are parallelograms (33. and 34. 1. E.) and as the angles D C *h* and C *h* H, that is (29. 1. E.) the angles DC *h* and *h* C *d* are equal to two right angles, DC and C *d* lie in one and the same straight line (14. 1. E.) therefore DC *d* is a diameter, and as D C=H *h*=C *d* (33. 1. E.) the diameter is bisected at C.

Prop X.

The tangents at the vertices of any diameter are parallel.

Fig. 13. Let D *d* be a diameter, and HDK, *h d k* tangents at its vertices. Draw straight lines from D and *d* to F and *f* the foci. The triangles FCD, *f*C *d* are in all respects equal, for FC=*f*C, CD=C*d*, and the angles FCD, *f*C *d* are equal; therefore the angles CDF, C *d f* are equal, and the lines DF, *d f* are parallel (29. 1. E.) and since DF=*d f*, the figure FD *f d* is a parallelogram, of which the opposite angles D, *d* are equal (34. 1. E.) Now the angles FDH, *f d h*, are half the supplements of these angles (8.) therefore the angles FDH, *f d h* are equal; and hence CDH, C *d h* are also equal, consequently HD is parallel to *h d*. (27. 1. E.)

Cor. 1. If tangents be drawn to an ellipse at the vertices of a diameter; straight lines drawn from either focus to the points of contact make equal angles with these tangents. For the angle FDH is equal to F *d k*.

Cor. 2. The axes of an ellipse are the only diameters which are perpendicular to tangents at their vertices. For let D *d* be any other diameter, then FD, F *d* are necessarily unequal, and therefore the angles FD *d*, F *d* D are unequal, and adding the equal angles FDH, F *d k*, the angles HD *d*, *k d* D are unequal, therefore neither is a right angle. (29. 1. E.)

Prop. XI.

A straight line drawn from either focus of an ellipse to the intersection of two tangents to the curve, will make equal angles with straight lines drawn from the same focus to the points of contact.

Fig. 14. Let HD, H *d* be tangents to an ellipse at the points D, *d*, let a straight line be drawn from H their intersection to F either of the foci, and let FD, F *d* be drawn to the points of contact, the lines DF, *d* F make equal angles with HF. For draw D*f*, *d f* to the other focus, and in FD, F *d* produced, take DK=D *f* and *dk*=*d f*; join HK, H*k*, and draw *f* K, *f k* meeting the tangents at G and *g*. The triangles *f* DH, KDH have D*f*=DK; and DH common to both, also the angle *f* DH equal to KDH (8.) therefore *f* H=KH. In like manner it may be shewn that *f* H=*k* H; therefore HK=H*k*. Now FK=F*k*, for each is equal to FD+D*f*, or F*d*+*d f*, that is to the transverse axis (1.) therefore the triangles FKH, F *k* H are in all respects equal, and hence the angle KFH is equal to *k* FH, therefore DF and *d* F make equal angles with HF.

Cor. 1. Perpendiculars drawn from the intersection of two tangents to straight lines drawn from either focus through the points of contact are equal. For HI, H *i*, perpendiculars to FD, F *d* are manifestly equal (26. 1. E.)

Cor. 2. Straight lines drawn from the intersection of two tangents to the foci make equal angles with the tangents. For the angles FHK, FH *k* being equal, and FHK=FHD+DHK=FHD+DH *f*=2 FHD+FH *f*, and in like manner FH *k*=FH*d*+*d* H *f*=2 *f* H *d*+FH *f*, therefore 2 FHD+FH *f*=2 *f* H *d*+FH*f*, and 2 FHD=2 *f* H *d*, and FHD=*f* H *d*.

Prop. XII.

Ellipse. If there be two tangents at the extremities of a chord in the ellipse, and a third parallel to the chord, the part of this tangent intercepted between the other two is bisected at the point of contact.

Let HD, H*d* be tangents at the extremities of the chord D *d*, and KP*k* another tangent parallel to the chord; and meeting the others in K and *k*; the line K *k* is bisected at P, the point of contact. From the points of contact D, P, *d*, draw lines to F, either of the foci; and from the intersections of each two tangents, draw perpendiculars to lines drawn through the focus from the points of contact, that is draw HI, H *i* perpendicular to FD, F *d*; and KM, K *m* perpendicular to FD, FP; and *k*N, *kn*, perpendicular to F *d*, FP. The triangles DHI, DKM are manifestly equiangular; as also *d* H *i*, *d k* N; therefore, DH : DK : : HI : KM (4. 6. E.) and *d*H : *d k* : : H *i* : *k*N; but K *k* being parallel to D*d*; DH : DK : : *d*H : *d k*; therefore HI : KM : : H*i* : *k*N; now HI=H*i* (Cor. 1. 11.) therefore KM=*k* N, but KM=K *m*, and *k* N=*k n* (Cor. 1. 11.) therefore K *m*=*k n*, and since we have manifestly K*m* : *k n* : : KP : *k* P, (4. 6. E.) therefore KP=*k* P. Fig. 15.

Lemma.

Let HK′*k*′ be a triangle, having its base K′*k*′ bisected at *p*; and let K *k*, any straight line parallel to the base, and terminated by the sides, be bisected at P, then the points *p*, P, and the vertex of the triangle are in the same straight line: and that line bisects D*d*, any other straight line parallel to the base. Fig. 16.

Complete the parallelograms HK′*p*T, HKPS. The triangles, HK*k*, HK′*k*′ being similar, and K*k*, K′*k*′ similarly divided at P and *p*, we have HK : HK′ : : K *k* : K′ *k*′ : : KP : K′*p*; hence the parallelograms HKPS, HK′*p*T are similar. Now they have a common angle at H; therefore they are about the same diameter, (26. 6. E.) that is, the points H, P, *p*, are in a straight line. And if D*d* meet that line in E, we have KP : DE (: : PH : EH) : : P*k* : E *d*, therefore DE=E*d*.

Definitions.

12. Any chord not passing through the centre, which is bisected by a diameter, is called an ordinate to that diameter.

13. The segments into which an ordinate divides a diameter are called *Abscissæ*.

Prop. XIII.

Any chord not passing through the centre, but parallel to a tangent, is bisected by the diameter which passes through the point of contact; or it is an ordinate to that diameter.

The chord DE *d*, which is parallel to K *k*, a tangent at P is bisected at E by the diameter P *p*. Draw K′*p k*′ a tangent at *p*, the other end of the diameter; and DH, *d* H tangents at D, *d*, the extremities of the chord meeting the other tangents in K, *k*, and K′*k*′. Then KP *k* and K′*p k*′ are bisected at P and *p* (12.) therefore the diameter P*p*, when produced, must pass through H, and bisect D *d*, which is parallel to K′ *k*′ or K *k* in E (Lemma.) Fig. 17.

Cor. 1. Straight lines which touch an ellipse at the extremities of an ordinate to any diameter intersect each other in that diameter.

Cor. 2. Every ordinate to a diameter is parallel to a tangent at its vertex. For if not, let a tangent be

Ellipse.

drawn parallel to the ordinate, then the diameter drawn through the point of contact would bisect the ordinate, and thus the same line would be bisected in two different points, which is absurd.

Cor. 3. All the ordinates to the same diameter are parallel to each other.

Cor. 4. A straight line that bisects two parallel chords, and terminates in the curve, is a diameter.

Cor. 5. The ordinates to either axis are perpendicular to that axis, and no other diameter is perpendicular to its ordinates.

Prop. XIV.

If a tangent to an ellipse meet a diameter, and from the point of contact an ordinate be drawn to that diameter, the semidiameter is a mean proportional between the segments of the diameter, intercepted between the centre and the ordinate, and between the centre and the tangent.

Fig. 17. Let DH a tangent to the curve at D meet the diameter P p produced in H; and let DEd be an ordinate to that diameter, then CE : CP : : CP : CH.

Through P and p the vertices of the diameter, draw the tangents PK, pK′, meeting DH in K and K′; draw PF, pF, DF to either of the foci, and draw KM, Km perpendicular to FP and FD, and K′N K′n perpendicular to Fp, FD. The triangles PKM, pK′N are equiangular, for the angles at M and N are right angles, and the angles MPK, NpK′ are equal, (1. Cor. 10.) therefore PK : pK′ : : KM : K′N (4. 6. E.) : : Km : K′n (1. Cor. 11.) but the triangles KmD, K′nD being manifestly equiangular, Km : K′n : : KD : K′D, therefore PK : pK′ : : KD : K′D : But because of the parallel lines KP, DE, K′p, we have PK : pK′ : : PH : pH and KD : K′D : : PE : pE, therefore PH : pH : : PE : pE; take CG=CE, then, by conversion, PH : Pp : : PE : EG; and taking the halves of the consequents, PH : PC : : PE : EC; hence, by composition, HC : PC : PC : EC.

Cor. 1. The rectangle PE.Ep is equal to the rectangle HE.EC.

For PC^2=HC.CE=HE.EC+EC^2 (17. 6. and 3. 2. E.)
also PC^2=PE.Ep+EC^2 (5. 2. E.)
therefore HE.EC=PE.Ep.

Cor. 2. PH Hp=EH.HC.
For HC^2=PH.Hp+CP^2 (6. 2. E.)
also HC^2=EH.HC+EC HC (1. 2. E.)
=EH.HC+CP^2 (by the Prop.)
Therefore PH.Hp=EH.HC.

Prop. XV.

If a diameter of an ellipse be parallel to the ordinates of another diameter, the latter diameter shall be parallel to the ordinates of the former.

Fig. 18. Let Qq a diameter of an ellipse be parallel to DEd an ordinate to the diameter Pp; the diameter Pp shall be parallel to the ordinates of the diameter Qq.

Draw the diameter dCD′ through one extremity of the ordinate Dd, and join D′ and D the other extremity, meeting Qq in G. Because D′d is bisected at C, and CG is parallel to dD, the line DD′ is bisected at G; therefore DD′ is an ordinate to the diameter Qq; and because dD′ and dD are bisected at C and E; the diameter Pp is parallel to DD′ (2. 6. E.) therefore, Pp is parallel to any ordinate to the diameter Qq.

Definitions.

14. Two diameters are said to be *conjugate* to one another, when each is parallel to the ordinates of the other diameter.

Cor. Diameters which are conjugate to one another are parallel to tangents at the vertices of each other.

15. A third proportional to any diameter and its conjugate is called the *Parameter*, also the *Latus rectum* of that diameter.

Prop. XVI.

If an ordinate be drawn to any diameter of an ellipse, the rectangle under the segments of the former will be to the square of the semiordinate as the square of the diameter to the square of its conjugate.

Let DEd be an ordinate to the diameter Pp, and let Qq be its conjugate, then, PE.Ep : DE^2 : : Pp^2 : Qq^2. Fig. 18.

Let KDL, a tangent at D, meet the diameter in K, and its conjugate in L; draw DG parallel to Pp, meeting Qq in G. Because CP is a mean proportional between CE and CK. (14.)

CP^2 : CE^2 : : CK : CE (2. Cor. 20. 6. E.)
and by division, CP^2 : PE.Ep : : CK : KE;
But because ED is parallel to CL,
CK : KE : : CL : DE or CG;
and because CQ is a mean proportional between CG and CL (14.)
CL : CG : : CQ^2 : CG^2 or ED^2;
therefore, CP^2 : PE.Ep : : CQ^2 : DE^2;
and by inversion, and alternation,
PE.Ep : DE^2 : : CP^2 : CQ^2 : : Pp^2 : Qq^2.

Cor. 1. The squares of semi-ordinates, and ordinates, to any diameter of an ellipse, are to one another as the rectangles contained by the corresponding abscissæ.

Cor. 2. The ordinates to any diameter, which intercept equal segments of that diameter from the centre, are equal to one another, and conversely equal ordinates intercept equal segments of the diameter from the centre.

Cor. 3. If a circle be described upon Aa, either of the axes of an ellipse, as a diameter, and DE, de any two semiordinates to the axis meet the circle in H and h; DE : de : : HE : he. For DE^2 : de^2 : : AE.Ea : Ae.ea : : HE^2 : he^2, therefore DE : de : : HE : he. Fig. 19.

Cor. 4. If a circle be described on Aa, the transverse axis, as a diameter, and DE, any ordinate to the axis, be produced to meet the circle in H, then HE : DE : : Aa : Bb, the conjugate axis. For produce the conjugate axis to meet the circle in K, then (by last Cor.) HE : DE : : KC or AC : BC : : Aa : Bb.

Cor. 5. If HE be divided at D, so that HE is to DE as the transverse to the conjugate axis, D is a point in the ellipse, and DE is a semiordinate to the axis Aa.

Prop. XVII.

The transverse axis of an ellipse is the greatest, and the conjugate axis the least, of all its diameters.

Let Aa be the transverse axis, Bb the conjugate axis, and CD any semidiameter. Draw DE perpendicular to Aa, and DL perpendicular to Bb; and because Aa^2 : Bb^2 : : AE.Ea : DE^2 (16.) and Aa^2 is greater than Bb^2, therefore AE.Ea is greater than DE^2; and AE.Ea+EC^2 is greater than DE^2+EC^2; that is AC^2 is greater than DC^2, therefore, AC is greater than DC. Fig. 19.

By the same manner of reasoning it may be shewn, that because Bb^2 is less than Aa^2, BL.Lb+CL^2 is

Ellipse. less than DL^2+CL^2, that is BC^2 is less than DC^2, and BC less than DC.

PROP. XVIII.

If an ordinate be drawn to any diameter of an ellipse, the rectangle contained by the abscissæ is to the square of the semiordinate as the diameter to its parameter.

Fig. 20. Let DE be a semiordinate to the diameter Pp, let PG be the parameter of the diameter, and Qq the conjugate diameter: By Def. 15. $Pp : Qq :: Qq : PG$; therefore, $Pp : PG :: Pp^2 : Qq^2$ (2 Cor. 20. 6. E.), but $Pp^2 : Qq^2 :: PE.Ep : DE^2$ (16.); therefore, $PE.Ep : DE^2 :: Pp : PG$.

COR. 1. Let the parameter PG be perpendicular to the diameter Pp; join PG, and from E draw EM parallel to PG, meeting PG in M. The square of DE, the semiordinate, is equal to the rectangle contained by PE and EM.

For $PE.Ep : DE^2 :: Pp : PG$, and
$Pp : PG :: Ep : EM : PE.Ep : PE.EM$,
Therefore $DE^2 = PE.EM$.

SCHOLIUM.

If the rectangles PGLp, HGKM be completed, it will appear that ED^2 is equal to the rectangle MP, which rectangle is less than the rectangle KP contained by the abscissa PE, and parameter PG, by a rectangle KH similar, and similarly situated to LP, the rectangle contained by the diameter and its parameter. It was on account of the deficiency of the square of the ordinate from the rectangle contained by the abscissa and parameter, that Apollonius called the curve, to which the property belonged, an *Ellipse*.

PROP. XIX.

If from the vertices of two conjugate diameters of an ellipse, there be drawn ordinates to any third diameter, the square of the segment of that diameter intercepted between either ordinate and the centre, is equal to the rectangle contained by the segments between the other ordinate and the vertices of the same diameter.

Fig. 21. Let Pp, Qq be two conjugate diameters, and PE, QG semiordinates to any third diameter Aa, then $CG^2 = AE.Ea$; and $CE^2 = AG.Ga$. Draw the tangents PH, QK meeting Aa in H and K. The rectangles HC.CE and KC.CG are equal; for each is equal CA^2 (14.), therefore $HC : CK :: CG : CE$. But the triangles HPC, CQK are evidently similar (Cor. Def. 14.), and PE being parallel to QG, their bases CH, KC are similarly divided at E and G, therefore $HC : CK :: HE : CG$; wherefore $CG : CE :: HE : CG$, consequently $CG^2 = CE.EH =$ (Cor. 1. 14.) $AE.Ea$. In like manner it may be shewn, that $CE^2 = AG.Ga$.

COR. 1. Let Bb be the diameter that is conjugate to Aa; then Aa is to Bb, as CG to PE, or as CE to QG.

For $Aa^2 : Bb^2 :: AE.Ea$, or $CG^2 : PE^2$, therefore $Aa : Bb :: CG : PE$. In like manner $Aa : Bb :: CE : QG$.

COR. 2. The sum of the squares of CE, CG, the segments of the diameter to which the semiordinates PE, QG are drawn, is equal to the square of CA, the semidiameter.

For $CE^2 + CG^2 = CE^2 + AE.Ea = CA^2$.

COR. 3. The sum of the squares of any two conjugate diameters, is equal to the sum of the squares of the axes.

Let Aa, Bb be the axes, and Pp, Qq any two conjugate diameters; draw PE, QG perpendicular to Aa, and PL, QM perpendicular to Bb; then $CE^2 + CG^2 = CA^2$, and $CM^2 + CL^2$, or $GQ^2 + PE^2 = CB^2$; therefore $CE^2 + PE^2 + CG^2 + GQ^2 = CA^2 + CB^2$; that is (47. 1. E.), $CP^2 + CQ^2 = CA^2 + CB^2$, therefore $Pp^2 + Qq^2 = Aa^2 + Bb^2$.

PROP. XX.

If four straight lines be drawn touching an ellipse at the vertices of any two conjugate diameters, the parallelogram formed by these lines is equal to the rectangle contained by the transverse and conjugate axes.

Let Pp, Qq be any two conjugate diameters, the parallelogram VXYZ formed by tangents to the curve at their vertices, is equal to the rectangle contained by Aa, Bb the two axes. Produce Aa, one of the axes, to meet the tangent pY in N, join QN, and draw pI, QG perpendicular to Aa. Because $CN : CA :: CA : CI$ (14.), and $CA : CB :: CI : QG$ (1 Cor. 19.) ex æq. $CN : CB :: CA : QG$, therefore $CN.QG = CB.CA$. But $CN.QG =$ twice trian. CNQ = paral. $CpYQ$, therefore the parallelogram $CpYQ = CB.CA$, and taking the quadruple of these, the parallelogram VXYZ is equal to the rectangle contained by Aa and Bb. Fig. 21.

PROP. XXI.

If two tangents, at the vertices of any diameter of an ellipse, meet a third tangent, the rectangle contained by their segments, between the points of contact and the points of intersection, is equal to the square of the semi-diameter to which they are parallel. And the rectangle contained by the segments of the third tangent, between its point of contact and the parallel tangents, is equal to the square of the semi-diameter to which it is parallel.

Let PH, ph, tangents at the vertices of a diameter Pp, meet HDh, a tangent to the curve, at any point D in H and h. Let CQ be the semi-diameter, to which the tangents PH, ph are parallel, and CR that to which Hh is parallel, then $PH.ph = CQ^2$, and $DH.Dh = CR^2$. If the tangent HDh be parallel to Pp, the proposition is manifest. If it is not parallel, let it meet the semidiameters CP, CQ in L and K. Draw DE, RM parallel to CQ, and DG parallel to CP. Because $LP.Lp = LE.LC$ (2 Cor. 14.) $LP : LE :: LC : Lp$, and because PH, ED, CK, ph, are parallel, $PH : ED :: CK : ph$, wherefore $PH.ph = ED.CK$; but $ED.CK = CG.CK = CQ^2$ (14.), therefore $PH.ph = CQ^2$. Again, the triangles LED, CMR are evidently similar; and LE, LD similarly divided at P and H, also at p and h, therefore $PE : HD :: (LE : LD ::) CM : CR$, also $pE : hD :: (LE : LD) CM : CR$, hence taking the rectangles of the corresponding terms, $PE.pE : HD.hD :: CM^2 : CR^2$. But if CD be joined, the points D and R are evidently the vertices of two conjugate diameters (Cor. Def. 14.) and therefore $PE.pE = CM^2$ (19.), therefore $HD.hD = CR^2$. Fig. 22.

COR. The rectangle contained by LD and DK, the segments of a tangent intercepted between D the point of contact and Pp, Qq, any two conjugate diameters is equal to the square of CR, the semi-diameter to which the tangent is parallel. Let the parallel tangents PH, ph meet LK in H and h, and draw DE a semi-ordinate to Pp. Because of the parallels PH, ED, CK, ph, $LE : LD :: EP : DH$, and $EC : DK :: Ep : Dh$, therefore $LE.EC : LD.DK :: EP.Ep : DH.Dh$. But $LE.EC = EP.Ep$ (1. Cor. 14.), therefore $LD.DK = DH.Dh =$ (by this Prop.) CR^2.

Ellipse.

Prop. XXII.

Fig. 23. If two straight lines be drawn from the foci of an ellipse perpendicular to a tangent, straight lines drawn from the centre to the points in which they meet the tangent, will each be equal to half the transverse axis.

Let DPd be a tangent to the curve at P, and FD, fd perpendiculars to the tangent from the foci; the straight lines joining the points C, D, and C, d are each equal to AC, half the transverse axis. Join FP, fP, and produce FD, fP till they intersect in E. The triangles FDP, EDP, have the angles at D right angles, and the angles FPD, EPD equal (8.), and the side DP common to both, they are therefore equal, and consequently have ED=DF, and EP=PF, wherefore Ef=FP+Pf=Aa. Now, the straight lines FE, Ff being bisected at D and C, the line DC is parallel to Ef (2. 6. E.); and thus the triangles FfE, FCD are similar; therefore Ff : fE or Aa : : FC : CD; but FC is half of Ff, therefore CD is half of Aa. In like manner it may be shewn, that Cd is half of Aa.

Cor. If the diameter Qq be drawn parallel to the tangent Dd, it will cut off from PF, Pf, the segments PG, Pg, each equal to AC, half the transverse axis. For CdPG, CDPg are parallelograms, therefore PG=dC, and Pg=DC=AC.

Prop. XXIII.

The rectangle contained by perpendiculars drawn from the foci of an ellipse to a tangent, is equal to the square of half the conjugate axis.

Fig. 23. Let DPd be a tangent, and FD, fd, perpendiculars from the foci, the rectangle contained by FD and fd is equal to the square of CB, half the conjugate axis.

It is evident from the last proposition, that the points D, d are in the circumference of a circle, whose centre is the centre of the ellipse, and radius CA half the transverse axis; now FDd being a right angle, if dC be joined, the lines DF, dC, when produced, will meet at H, a point in the circumference (31. 3. E.); and since FC=fC, and CH=Cd, and the angles FCH, fCd are equal, FH is equal to fd, therefore DF.df=DF.FH =AF.Fa (35. 3. E.) =CB², (2. Cor. 3.)

Cor. If PF, Pf be drawn from the point of contact to the foci, the square of FD is a fourth proportional to fP, FP, and BC². For the lines fP, FP make equal angles with the tangent (8.), and fdP, FDP are right angles, therefore the triangles fPd, FPD are similar, and fP : FP : : (fd : FD : :) fd.FD or CB² : FD².

Prop. XXIV.

Fig. 24. If from C, the centre of an ellipse, a straight line CL be drawn perpendicular to a tangent LD, and from D, the point of contact, a perpendicular be drawn to the tangent, meeting the transverse axis in H, and the conjugate axis in h, the rectangle contained by CL and DH is equal to the square of CB, the semi-conjugate axis; and the rectangle contained by CL and Dh is equal to the square of CA, the semi-transverse axis.

Produce the axes to meet the tangent in M and m, and from D draw the semi-ordinates DE, De, which will be perpendicular to the axis.

The triangles DEH, CLm are evidently equiangular, therefore DH : DE : : Cm : CL, hence CL.DH=DE.Cm; but DE.Cm, or Ce.Cm=BC², therefore CL.DH=BC². In the same manner it is shewn, from the triangles Dhe, CLM, that CL.Dh=AC².

Cor. 1. If a perpendicular be drawn to a tangent at the point of contact, the segments, intercepted between the point of contact and the axes, are to each other reciprocally as the squares of the axes by which they are terminated.

For AC² : BC² : : CL.Dh : : CL.DH : : Dh : DH.

Cor. 2. If DF be drawn to either focus, and HK be drawn perpendicular to DF, the straight line DK shall be equal to half the parameter of the transverse axis. Draw CG parallel to the tangent at D, meeting DH in N, and DF in G. The triangles GDN, HDK are similar; therefore GD : DN : : HD : DK, and hence GD.DK=HD.DN. But GD=AC, (Cor. 22.) and ND=CL, therefore AC.DK=HD.CL= (by the Prop.) CB²; wherefore AC : BC : : BC : DK, hence DK is half the parameter of Aa, (Def. 15.)

Prop. XXV.

Let Aa, Bb be the transverse aud conjugate axes of an ellipse; from K, any point in the conjugate axis, let a straight line KH, which is equal to the sum or difference of the semi-axes CA, CB, be placed so as to meet the transverse axis in H, and in KH, produced beyond H, when KH is the difference of the semi-axis, let HD be taken equal to CB, the point D is in the ellipse. Fig. 25.

Draw DE perpendicular to Aa, and through C draw CG parallel to KD, meeting ED in G, then CG=KD =AC by construction; hence G is in the circumference of a circle, of which C is the centre, and CA the radius; and because the triangles CEG, HED are similar, GE : DE : : CG : HD : : CA : CB, therefore DE is a semiordinate, and D a point in the ellipse, (Cor. 5. 16.)

Scholium.

The instrument called the *trammels*, and likewise the *elliptical compasses*, which workmen use for describing elliptic curves, are constructed on the property of the curve demonstrated in this proposition.

Prop. XXVI. *Problem.*

An ellipse being given by position to find its axes.

Let ABab be the given ellipse, draw two parallel chords Hh, Kk, and bisect them at L and M; join LM, and produce it to meet the ellipse in P and p, then Pp is a diameter, (4. Cor. 13.) Bisect Pp in C, the point C is the centre of the ellipse (9.) Take D any point in the ellipse, and on C as a centre, with the distance CD describe a circle. If this circle fall wholly without the curve, then CD must be half the transverse axis; and if it fall wholly within the curve, then CD must be half the conjugate axis (17.) If the circle neither fall wholly without the curve nor within it, let the circle meet it again in d; join Dd, and bisect Dd in E, join CE, which produce, to meet the ellipse in A and a, then Aa will be one of the axes (5. Cor. 13.), for it is perpendicular to Dd (3. 3. E.), which is an ordinate to Aa. The other axes Bb will be found, by drawing a straight line through the centre perpendicular to Aa. Fig. 26.

SECTION III.

Of the Hyperbola.

Definitions.

1. Let F, f be two given points, and PQ, pq two straight lines between these points, equally distant from Fig. 27.

Hyperbola. C, the middle of the line joining them, and perpendicular to that line at P and p; and in the same line, let CA and Ca be taken in contrary directions, each a mean proportional between CF and CP; then, if a point D be conceived to move in the plane of the lines, in such a manner, that DF its distance from one of the given points, has to DE its distance from the given line adjacent to that point, the given ratio of CF to CA, and consequently so that Df its distance from the other given point has to De its distance from the other given line the same given ratio, (Sect. I. Prop. 1.) the point D will describe a curve line called an *Hyperbola.*

2. Each of the lines PQ, pq is called a *directrix.*

3. Each of the points F, f is called a *focus.*

4. The given ratio of CF to CA is called the *determining ratio.*

5. The point C is called the *centre* of the hyperbola.

Cor. to Def. 1. 3. 4. If Mm be drawn through F at right angles to Ff, and FM, Fm be taken, so that FM and Fm are each to FP in the determining ratio, the points M, m are in the hyperbola, and these are the only points in which the line Mm can meet the curve.

Def. 6. The straight line Aa is called the *transverse axis.*

7. The extremities of the transverse axis are called the *vertices.*

8. The distance of either focus from the centre is called the *eccentricity.*

Corollaries to Def. 1, 3, 4, 6.

1. The hyperbola passes through the extremities of the transverse axis. For since CA : CP : : CF : CA, therefore CF—CA : CA—CP : : CF : CA (19. 5. E.) that is, FA : AP : : CF : CA. Again, since Ca : CP : : CF : Ca, therefore, Ca+CF : CP+Ca : : CF : Ca, that is Fa : aP : : CF : Ca, or CA, therefore A and a are points in the hyperbola.

2. The distance between the foci has to the transverse axis, and the transverse axis has to the distance between the directrices, the determining ratio.

Prop. I.

Fig. 28. The difference between two straight lines drawn from any point D in the hyperbola to the foci is equal to the transverse axis.

$$\left.\begin{array}{l}\text{For } ED : DF :: Pp : Aa \\ \text{and } eD : Df :: Pp : Aa\end{array}\right\}\text{Cor. 2. to Def. 1. 3. 4. 6.}$$

$$\text{therefore } eD—ED : Df—DF :: Pp : Aa.$$

$$\text{But } eD—ED = Pp, \text{ therefore } Df—DF = Aa.$$

Scholium.

This property of the hyperbola affords a good definition of the curve, and has been employed as such by many writers on conics. The following mechanical description is also derived from it: Let one end of a string be fastened at F, (Fig. 28.) either of the foci, and the other to E, the extremity of a ruler fDE, and let the difference between the length of the string and the length of the ruler be equal to Aa, the transverse axis. Let the other end of the ruler be fixed at the other focus f, and let it revolve about f as a centre in the plane of the figure, while the string is stretched by means of a pin at D, so that the part of it between E and D is applied close to the edge of the ruler. By the revolution of the ruler, the lines Df, DF will manifestly be equally increased, and therefore their difference will always be the same quantity, viz. the line Aa; hence the point D will describe a branch of a hyperbola, of which Aa is the transverse axis, and F, f the foci. The other branch may be described, by fixing the end of the ruler to the other focus.

Hyperbola.

Prop. II.

Let FM be a perpendicular to the transverse axis at either focus, which meets the hyperbola at M, and let a circle be described on F as a centre, with FM as a radius; then, if from any point in the curve, a line DF be drawn to, or through the focus, meeting the circle in I, so that the points D, I may be on contrary sides, or the same side of the focus, according as the focus and the point D are on the same side or contrary sides of the directrix, and let IN be perpendicular to the axis, then the rectangle contained by the lines FD.PN is equal to the constant rectangle PF.FM. Fig. 29. No. 1, 2.

Join EF and PI, and because FM or FI : FP : : FD : DE (Cor. to Def. 1—4.), and (from the position of the lines) the angles FDE, IFP are equal (29. 1. E.) the triangles FDE, IFP are similar (6. 6. E.), and the angles DFE, FIP equal; hence FE is parallel to PI (2. 1. E.): Therefore the triangles FPE, PNI having the angles at F and P equal (29. 1. E.), and the angles at P and N being right angles, the triangles are equiangular: And because FD : FE : : IF : IP, and FE : FP : : IP : PN, ex æq. FD : FP : : IF or FM : PN (22. 5. E.), and FD.PN=FP.FM.

Cor. Hence it is evident how the point in which a straight line drawn from the focus meets the curve may be found, viz. by taking FD a fourth proportional to PN, FM and FP.

Scholium.

From this proposition we may acquire a correct notion of the figure of the curve, by considering the changes which take place in the magnitude of the line FD, while the angle PFD increases. Let us suppose the line FD to come to the position FA on the same side of the directrix as the focus (Fig. 29. No. 1.), then the point N will recede to L the extremity of the diameter farthest from P; and as PN will then be the greatest possible, FD will be the least. Suppose now the line FD to depart from the position FA, and to revolve about F, then the angle DFP increasing, the point N will approach to P; and as the rectangle FD.PN has always the same magnitude, the line FD must increase. Now, the determining ratio being a ratio of majority, and FM to FP in that ratio (Cor. to Def. 1—4.), FP must be less than FM; therefore P falls within the circle: hence it follows that PN may become less, and consequently FD greater than any assignable quantity. If we suppose the point I to arrive at last at K, one of the intersections of the directrix and circle, then the line PN altogether vanishes; therefore, corresponding to this position, there can be no intersection of the curve and the revolving line FD. By supposing the line FD to depart from the position FA, and to revolve in the contrary direction, or from A towards m, it will appear that it increases continually, until FI, its prolongation, arrive at the position Fk, (k being the other intersection of the directrix and circle), and here the point in which the line meets the hyperbola again has no existence. Fig. 29. No. 1.

If we now suppose the line FD (Fig. 29. No. 2.) which is drawn from the focus F to the part of the hyperbola on the other side of the directrices, to come to the position Fa, and departing from thence, to re- Fig. 29. No. 2.

volve about F, first on one, and then on the other side of the axis, until in the one case it come to the position F k, and in the other to FK, it will appear that PN, one side of the constant rectangle FD.PN, will pass through all gradations of magnitude from PL′ its greatest value, until it at last vanish, and consequently that PD the other side will increase continually, from P a its least value, until it exceed any assignable quantity. Moreover, the hyperbola does not meet either of the lines FK, Fk.

We may conceive the very same construction to be made at the other focus f, as has been made at F, in both figures; so that, upon the whole, we may draw the following conclusions.

1. The hyperbola consists of two parts entirely separate from each other, and having the directrices between them; and each is bent at the vertex into two branches, which lie on opposite sides of the transverse axis produced both ways.

2. If a circle be described on F, either focus, as stated in the proposition, and straight lines KFX, kFx be drawn from its intersections with the directrix through the focus, and produced indefinitely, the part of the hyperbola which is on the same side of the directrix will lie entirely in the space bounded by the directrix and the lines FX, Fx, and it will not meet these lines, and the other part will be entirely contained in the angle yFY, formed by these lines produced the contrary way.

3. The vertices are the points of the curve nearest to either focus, and of lines drawn from a focus to the curve, those nearer the vertex are less than those more remote. And the curve goes off indefinitely from both foci, and from the prolongation of the axis.

4. Lines drawn from a focus to the curve, so as to make equal angles with the axes on either side of it, are equal to one another.

Definitions.

9. The two parts of an hyperbola, which lie on opposite sides of the centre, are termed opposite *branches of the hyperbola.*

Fig. 27. 10. If a straight line Bb be perpendicular to the transverse axis at the centre C, and BA, b A, the distance of its extremities from either vertex, be equal to FC the eccentricity; the line B b is called the *Conjugate axis.*

Note. The conjugate axis of the hyperbola is not limited in its magnitude by the figure of the curve, as is that of the ellipse; it is an artificial axis introduced conventionally, in order to preserve the analogy between certain properties of the two curves.

Cor. to Def. 10. The conjugate axis is bisected at the centre of the hyperbola.

Prop. III.

The square of the semiconjugate axis is equal to the rectangle contained by the distances of either focus from the vertices of the transverse axis.

Fig. 27. For $AB^2 = AC^2 + CB^2$ (47.1.E.) and FC^2 $(=AB^2)$ $=AC^2 + FA.Af$ (5. 2. E.) therefore $BC^2 = FA.Af$.

Cor. Let P be the point in which the directrix belonging to the focus F meets the axis; then, $BC^2 = PF.FC$. For $FC^2 = PF.FC + PC.FC$ (2. 2. E.) $= PF.FC + AC^2$, because $AC^2 = PC.CF$ (Def. 1.); but FC^2 or $AB^2 = CB^2 + AC^2$, therefore $PF.FC = CB^2$.

Definition.

11. A straight line which meets the hyperbola, and being produced does not cut it, is said to *touch* the curve, and is called a *Tangent.*

Prop. IV. *Problem.*

Having given the transverse axis, and a focus, and consequently its directrix, to find the points in which a straight line given by position, perpendicular to the axis, meets the hyperbola.

Let Aa be the transverse axis, F either focus, PQ the directrix, and L l the line given by position, which meets the axis in G. Draw FM perpendicular to the axis, meeting the curve in M; draw MPL, meeting the line, given by position in L. On F as a centre, with GL as a radius, describe a circle, meeting LG in D and d; and these will be two points in the curve. Fig. 30.

For join FD, Fd, and draw DE, de perpendicular to the directrix; and because the triangles PGL, PFM are similar, GL : GP : : MF : FP, or, since ED, ed are each equal to PG, and that FD and Fd are each equal to LG, FD : DE, also Fd : de : : MF : FP, that is, (Cor. to Def. 1. 3. 4.) in the determining ratio; therefore D and d are points in the hyperbola, (Def. 1.)

It appears that the problem can be resolved only when GL=FD is greater than GF. To determine the limits within which this happens, draw AH, a h perpendicular to the axis, meeting PL in H and h; and join FH, Fh. Then, by similar triangles, PF : FM : : PA : AH : : Pa : ah, but PF : FM : : PA : AF : : Pa : aF (Def. 1.) therefore AH=AF and ah=a F. Now let GL meet either of the lines FH, Fh in N, then GN=GF; but when G is any point in the axis Aa produced either way, GN or GF is less than GL; when it is at A or a, then GN or GF=GL, and when it is between A and a, then GN or GF is greater than GL; therefore the problem will be possible, only when the line L l meets the tranverse axis A a produced.

Cor. 1. Every straight line perpendicular to the transverse axis, at any point in the axis, produced either way, meets the hyperbola in two points and no more; at either extremity of the axis it meets the curve in one point only, and at any point between the extremities of the axis, it falls entirely without both branches of the hyperbole.

Cor. 2. Every chord perpendicular to the transverse axis is bisected by the axis.

Cor. 3. A perpendicular to the axis at either of its extremities is a tangent.

Cor. 4. The transverse axis divides the hyperbola into parts exactly alike.

Prob. V. *Problem.*

The transverse axis, and a focus, and consequently its directrix, being given to find the points in which a straight line given by position, parallel to the axis, meets the hyperbola.

Let EH, the line given by position, meet the directrix in E, and the conjugate axis, or that axis produced in H; draw FE from the focus, meeting HC in G. On G as a centre, with a radius, which is a mean proportional between EG and GF, describe a circle, meeting EH in D and d; and these will be two points in the hyperbola. Fig. 31.

Join DF, Df, and because EG : GD : : GD : GF and

Hyperbola.

that the angle at G is common to the triangles EGD, DGF; these triangles are similar (6. 6. E.) and ED : DF : : EG : GD, therefore $ED^2 : DF^2 :: EG^2 : GD^2$; but $EG^2 : GD^2 :: EG : GF$ (2. Cor. 20. 6. E.) that is, as PC to CF (2. 6. E.) and $PC : CF :: AC^2 : CF^2$ (Def. 1. and Cor. 2. 20. 6. E.) therefore $ED^2 : DF^2 :: AC^2 : CF^2$ and $ED : DF :: AC : CF$; hence D is a point in the hyperbola (Def. 1.) and in like manner it may be shewn, that d is a point in the hyperbola.

And because the point E must, from the position of the directrix, always fall between F and G, therefore DG, the mean proportional between GE and GF, will always be greater than GE, and consequently much greater than GH, the perpendicular from G on D d; hence whatever be the position of the given line EH, provided that it be parallel to the axis, the circle will always cut it in two points, so that in this case there is not any limitation to the possibility of constructing the problem.

Cor. 1. Every straight line parallel to the transverse axis meets the opposite branches of the hyperbola each in one point and no more.

Cor. 2. Every straight line parallel to the transverse axis, and terminating on opposite branches of the hyperbola, is bisected by the conjugate axis, or that axis produced.

Cor. 3. The two branches of the hyperbola are perfectly alike, so that if applied one on the other they would coincide.

Prop. VI.

Fig. 32.

If from any point Q in the directrix a straight line be drawn to meet the hyperbola in D, and LF l a parallel to the directrix passing through the focus in H, and if another straight line be drawn to D through F, and a perpendicular QK be drawn to FD; the lines FH, QK have to each other the determining ratio.

Draw DE perpendicular to the directrix, and let DF meet it in I. The triangles DHF, DQI are evidently equiangular (29. 1. E.) and the triangles QIK DIE are also equiangular, for the angles at K and E are right angles, and the angle at I is common to both, therefore (4. 6. E.) FH : FD (: : QI : ID) : : QK : DE, and by alternation FH : QK : : FD : DE, that is in the determining ratio.

Cor. 1. If a straight line QH meet the directrix in Q, and the parallel Ll in H; and if KF, a line which is not parallel to QH, have such a position that FH has to QK (the distance of KF from Q) the determining ratio, the lines QH, KF shall meet at a point D in the hyperbola: For then FD : DE : : FH : QK, that is in the determining ratio; therefore D is in the hyperbola (Def. 1.)

Cor. 2. If QF be drawn to the focus, and in FH, the parallel to the directrix, FL and Fl be taken in contrary directions, each to FQ in the determining ratio, then every straight line which meets the hyperbola will either pass between, or through the points L, l; For since, by hypothesis, FQ : FL : : KQ : FH, and since KQ, cannot exceed FQ; therefore FH cannot exceed FL.

Cor. 3. Any straight line drawn from Q to intersect the parallel Ll beyond the limits L, l falls entirely without both branches of the hyperbola.

Prop. VII. *Problem.*

Having given a focus, its directrix, and the determining ratio, to find the points in which a straight line given by position, and not parallel to the directrix, meets the hyperbola.

Hyperbola.

Fig. 33. Nos. 1, 2.

Case 1. Let XY (Fig. 33. No. 1. and No. 2.) the line given by position, pass through F the focus: draw FQ perpendicular to XY, meeting the directrix in Q, and in LF l, the line passing through the focus parallel to the directrix, take FL and F l each to FQ in the determining ratio, and join QL and Q l; then, if neither of the angles FQL, FQl be a right angle, as in Fig. 33. No. 1, the lines QL, Q l will meet XY in two points D, d, which will be points in the curve (as is evident from Cor. 1. Prop. VI.) But if one of the angles FQ l be a right angle, as in Fig. 33. No. 2. there will be only one intersection D. To determine the position which the line XY must have, in order that this may happen, produce it to meet the directrix in V, and draw FP perpendicular to the directrix: The triangle FPV being similar to VFQ or FQ l (8. 6. E.) we have FV : FP : : F l : FQ, that is in the determining ratio. Let M be an intersection of L l and the curve, and FM will have to FP the same ratio (Cor. to Def. 1—4) therefore FV = FM, and V is the point in which a circle described on F as a centre, with FM as a radius, meets the directrix.

Fig. 34. Nos. 1, 2.

Case 2. Next let the line given by position meet the parallel to the directrix in H, (Fig. 34. No. 1. and 2.) so that QF being drawn to the focus, and FL and F l taken to FQ in the determining ratio, it may fall between F and either of the points L, l. In QF take QN, so that HF may have to QN the determining ratio, that is, the ratio of FL to QF, then it is manifest that QN is less than QF. On Q as a centre, with QN as a radius, describe a circle, and draw FK, F k tangents to it, then if neither of these is parallel to the line QH, as in Fig. 34. No. 1. they will meet it in two points D, d, which will be points in the hyperbola, as is evident from Prop. 6. Cor. 1. But if, as in Fig. 34. No. 2. one of the tangents F k be parallel to the line QH, there will be only one intersection D. To determine the position which the line QH ought to have, that this may happen, let F k meet the directrix in V, and let FP be perpendicular to the directrix. The triangles FPV, QV k are evidently equiangular, therefore FV : FP : : VQ or FH : Q k, that is as FM to FP (Cor. to Def. 1—4.) hence FM = FV; and V is that point in which the directrix meets the circumference of a circle, of which FM is the radius and HQ, the line given by position, is parallel to FV.

Case 3. Lastly, let the line given by position, and which meets the directrix in Q, pass through one of the points l (Fig. 34. No. 1.) which are so taken that F l or FL has to FQ the determining ratio: Draw FD′ perpendicular to FQ, and if it is not parallel to Q l it will meet Q l in some point D′ which will be a point in the hyperbola (1. Cor. Prop. 6.) But if, (as in Fig. 3. No. 2.), FQ l is a right angle, FD will be parallel to Q l, and so the line Q l will not meet the curve at all. To determine the position of Q in this case, draw FV perpendicular to FQ meeting the directrix in V. Then the triangle FPV is similar to VFQ or FQ l (8. 6. E.) therefore FV : FP : : F l: FQ that is in the determining ratio; therefore FV = FM, and so V is the intersection of the directrix and a circle whose radius is FM, and QL is parallel to FV.

Cor. 1. The points L, l being determined as in the second and third cases, (Fig. 34. No. 1. and No. 2.), any straight line drawn from Q to pass between them, will either cut the hyperbola in one point only, or in two points, and no more. For the number of points in which the line cuts the curve must be the same as the number of tangents to the circle KN k which meet that line, as was shewn with respect to the ellipse (Sect. II. Prop. 7.)

Fig. 34. No. 1. Cor. 2. If from D d (Fig. 34. No. 1.) the points in which a straight line meets an hyperbola, straight lines DF, d F be drawn to either focus, these make equal angles with FQ, a straight line drawn from the focus to the point in which D d meets the directrix. For the triangles FQK, FQ k are in all respects equal (47. 1. E.) therefore the angles QFK, QF k are equal.

Cor. 3. The points L, l (Fig. 33. No. 2.) and the lines FV, F v being determined as in Case 3. If a line be drawn from Q through L or l, provided it be not parallel to one of the lines FV, F v, that line will be a tangent to the hyperbola.

Cor. 4. If any line whatever meet a hyperbola, it will either cut it in one point only, or in two points and no more, or it will touch it.

Fig. 35. Cor. 5. If two straight lines FD, FQ (Fig. 35.) which contain a right angle at the focus, meet the curve and the directrix in D and Q; the straight lines which join these points is a tangent to the hyperbola at D, and only one tangent can be drawn at that point.

It is evident from the third case, that QD is a tangent; and to prove that there is no other at D, draw any other line DQ′ meeting the directrix in Q′, and the parallel to the directrix in H; take FL to QF in the determining ratio, and draw Q′K perpendicular to FD: and because FH has to Q′K, and also FL has to QF the determining ratio; and Q′K is less than QF, therefore FH is less than FL; hence the line QH cuts the hyperbola (Cor. 1. of this Prop.) therefore no line besides DQ can be a tangent to the curve at D.

Cor. 6. Tangents DQ, dQ (Fig. 33. No. 1.) at the extremities of any focal chord, and a perpendicular to that chord at the focus, meet at the same point in the directrix.

Prop. VIII.

A tangent to the hyperbola makes equal angles with straight lines drawn from the point of contact to the foci.

Fig. 36. If the tangent be at either extremity of the transverse axis, the proposition is evidently true (3. Cor. 4.) In any other case, let it touch the curve at D, and meet the directrices in Q and q; draw DF, Df, to the foci, and DE e perpendicular to the directrices; and join FQ, f q. The triangles DEQ, D e q are manifestly equiangular; therefore DQ : DE : : D q : D e (4. 6. E.) but DE : DF : : D e : Df (Def. 1.) therefore ex æq. (22. 5. E.) DQ : DF : : D q : D f; hence it appears, that the triangles DFQ, Df q, which have the angles at F, f right angles (5. Cor. 7.) have the sides about one of their acute angles proportionals, therefore they are equiangular (7. 6. E.) and have the angles FDQ, fD q equal.

Definition.

12. A straight line passing through the centre and terminating both ways in an hyperbola, is called a *Transverse Diameter*. It is also sometimes called simply a *Diameter.*

Prop. IX.

Every diameter is bisected at the centre.

From D any point in the hyperbola draw the straight line DH d' parallel to the transverse axis, meeting the conjugate axis at H, and the opposite branch in d'; and draw the chord d' h d perpendicular to the transverse axis at h, and join H h, DC, dC. Then, DH = H d' (2. Cor. 5.) = C h (34. 1. E.) and HC = d' h = h d; hence the figures DH hC, HC d h are parallelograms (33. and 34. 1. E.) and since (29. 1. E.) the angles DCh and ChH, that is the angles DCh and hCd, are equal to two right angles, the line DC and Cd lie in the same straight line (14. 1. E.) or DC d is a diameter; moreover DC = H h = Cd, therefore the diameter DC d is bisected at C. Fig. 37.

Prop. X.

The tangents at the vertices of any transverse diameter of an hyperbola are parallel.

Let D d be a diameter, HD, h d tangents at its vertices; draw straight lines from D and d to F, and f the foci. The triangles FCD, fC d, having FC = fC, CD = Cd (9.) and the angles at C equal, are in all respects equal, and because the angle FDC is equal to C$d$$f$, FD is parallel to $f$$d$ (27. 1. E.), therefore Df is equal and parallel to F d (33. 1. E.); thus FD$f$$d$ is a parallelogram, of which the opposite angles D and d are equal (34. 1. E.); now the angles FDH, $f$$d$ h are the halves of these angles (8.); therefore the angles FDH, $f$$d$$h$, and hence CDH and C$d$$h$ are also equal, and consequently HD is parallel to h d. Fig. 38.

Cor. 1. If tangents be drawn to an hyperbola at the vertices of a transverse diameter, straight lines drawn from either focus to the points of contact, make equal angles with these tangents. For the angle Fd h is equal to FDH.

Cor. 2. The transverse axis is the only diameter which is perpendicular to tangents at its vertices. For let D d be any other diameter, the angle CDH is less than CDF, that is, less than the half of FDf; therefore CDH is less than a right angle.

Prop. XI.

A straight line drawn from either focus of an hyperbola to the intersection of two tangents to the curve will make equal angles with straight lines drawn from the same focus to the points of contact.

Let HD, H d be tangents to an hyperbola at the points D, d; let a straight line be drawn from H, their intersection to F, either of the foci; and let FD, F d be drawn to the points of contact; the lines DF, d F make equal angles with HF. Draw Df, df, and Hf to the other focus. In DF, d F take DK = Df, and d k = df; join HK, Hk, and let fK, $f$$k$ be drawn meeting the tangents in G and g. The triangles fDH, KDH have Df = DK, by construction, and DH common to both, also the angle fDH equal to KDH, (8.) therefore fH = KH. In like manner it may be shewn that fH is equal k H, therefore HK is equal to H k: now, F K is equal to F k, for each is equal to the difference between FD and fD, or F d and $f$$d$, that is, to the transverse axis; therefore the triangles FKH, F k H are in all respects equal, and hence the angle KFH is equal to k FH, therefore DF and d F make equal angles with HF. Fig. 39. Nos. 1, 2.

Cor. 1. Perpendiculars HI, H i drawn from the intersection of two tangents DH, d H to straight lines drawn from either focus through the points of contact are equal; for HI, Hi, perpendiculars to FD, F d, are manifestly equal (26. 1. E.)

Hyperbola.

COR. 2. Straight lines drawn from the intersection of any two tangents to the foci make equal angles with those tangents.

For produce FH to O any distance; and because the angles FHK, FHk are equal, the angles OHK, OHk are equal: but $\text{OHK}=\text{OH}f+2f\text{HD}$ and $\text{OH}k=k\text{H}g+\text{OH}g=f\text{H}g+\text{OH}g=\text{OH}f+2\,\text{OH}g$, therefore $\text{OH}f+2f\text{HD}=\text{OH}f+2\text{OH}g$; hence $2f\text{HD}=2\,\text{OH}g$ and $f\text{HD}=\text{OH}g=\text{OH}d$ (in Fig. 39. No 1.) or $f\text{HD}=\text{FH}d$ (in Fig. 39. No. 2.)

PROP. XII.

If there be two tangents at the extremities of a chord, and a third be parallel to the chord, the part of this tangent intercepted between the other two is bisected at the point of contact.

Fig. 40. Let HD, Hd be tangents at the extremities of the chord Dd, and KPk another tangent parallel to the chord, meeting the others in K and k; the line Kk is bisected at P the point of contact. From the points of contact D, P, d draw lines to F either of the foci, and from the intersection of each two tangents, draw perpendiculars to straight lines drawn from the focus through their points of contact; that is, draw HI, Hi perpendicular to FD, Fd and KM, Km perpendicular to FD and FP; and kN, kn perpendicular to Fd and FP. The triangles DHI, DKM are manifestly equiangular, as also $d\text{H}i$, $dk\text{N}$; therefore, DH : DK : : HI : KM; and dH : dk : : Hi : kN, but Kk being parallel to Dd, DH : DK : : dH : dk (2. 6. E.); therefore HI : KM : : Hi : kN, now HI = Hi (1. Cor. 11.) therefore KM = kN; but KM = Km, and kN = kn (1. Cor. 11.) therefore Km = Kn; and since we have manifestly Km : kn : : KP : kP (4. 6. E.) therefore KP=kp.

Definitions.

13. Any chord not passing through the centre which is bisected by a diameter, is called an *Ordinate* to that *diameter*.

14. The segments into which an ordinate divides a diameter are called *Abscissæ*.

LEMMA.

Fig. 41. Let HK$'k'$ be a triangle, having its base K$'k'$ bisected at p; and let Kk, any straight line parallel to the base, and terminated by the sides produced, be bisected at P, then P, p, the points of bisection, and H, the vertex of the triangle, are in a straight line, which bisects Dd any other straight line parallel to Kk.

Join HP, Hp. The triangles KHk, and K$'$Hk' being similar, and Kk, K$'k'$ similarly divided at P and p, we have HK : HK$'$ (: : Kk : K$'k'$) : : KP : K$'p$; now the angles at K and K$'$ are equal, therefore the triangles HKP, HK$'p$ are similar; and the angle PHK is equal to pHK$'$, and the sum of PHK and pHK is equal to the sum of pHK$'$ and pHK, that is to two right angles (13. 1. E.) therefore HP, Hp lie in the same straight line (14. 1. E.)

Again, let Dd meet HP in E, then KP : DE (: : PH : EH) : : Pk : Ed, but KP = Pk; therefore DE=Ed.

PROP. XIII.

Any chord not passing through the centre, but parallel to a tangent, is bisected by the diameter which passes through the point of contact, or it is an ordinate to that diameter.

The chord Dd, which is parallel to Kk a tangent at P, is bisected at E by the diameter Pp. Draw K$'pk'$ a tangent at p, the other end of the diameter, and DH, dH tangents at D, d, the extremities of the chord meeting the other tangents in K, k, and K$'$, k'. Then KPk and K$'pk'$ are bisected at P and p (12.) therefore the diameter Pp when produced must pass through H and bisect Dd, which is parallel to Kk or K$'k'$, in E (Lemma.) Fig. 42.

COR. 1. Straight lines which touch an hyperbola at the extremities of an ordinate to any transverse diameter, intersect each other in that diameter.

COR. 2. Every ordinate to a transverse diameter is parallel to a tangent at its vertex. For if not, let a tangent be drawn parallel to the ordinate, then the diameter drawn through the point of contact would bisect the ordinate, and then the same line would be bisected in two different points, which is absurd.

COR. 3. All the ordinates to the same transverse diameter are parallel to each other.

COR. 4. A straight line that bisects two parallel chords, and terminates in the opposite branches, is a transverse diameter.

COR. 5. The ordinates to the transverse axis are perpendicular to it, and no other transverse diameter has its ordinates perpendicular to it. This follows from Cor. 3. to 4. and Cor. 2. to 10.

PROP. XIV.

If a tangent to an hyperbola meet a transverse diameter, and from the point of contact an ordinate be drawn to that diameter, the semi-diameter will be a mean proportional between the segments of the diameter intercepted between the centre and the ordinate, and between the centre and the tangent.

Let DH, a tangent to the curve at D, meet the diameter Pp in H; and let DEd be an ordinate to that diameter; then CE : CP : : CP : CH. Through P and p, the vertices of the diameter, draw the tangents PK, pK$'$, meeting DH in K and K$'$: draw PF, pF, DF to either of the foci, and draw KM, Km perpendicular to FP and FD, and K$'$N, K$'n$ perpendicular to Fp, FD. The triangles PKM, pK$'$N are equiangular, for the angles at M and N are right angles, and the angles MPK, NpK$'$ are equal (1. Cor. 10.), therefore PK : pK$'$: : KM : K$'$N (4. 6. E.) : : Km : K$'n$ (1. Cor. 11.), but the triangles KmD, K$'n$D being manifestly equiangular, Km : K$'n$: : KD, K$'$D, therefore PK : pK$'$: : KD : K$'$D. But because of the parallel lines KP, DE, K$'p$, we have PK : pK$'$: : PH : pH, and KD : K$'$D : : PE : pE, therefore PH : pH : : PE : pE. Take CG= CE, then pG=PE, and (Cor. Prop. D. 5. E.) PH : Pp : : PE : EG, and taking the halves of the consequents, PH : PC : : PE : EC : hence by division HC : PC : : PC : EC. Fig. 42.

COR 1. The rectangle contained by PE and Ep is equal to the rectangle contained by HE and CE. For $\text{CP}^2=\text{HC.CE}=\text{EC}^2-\text{HE.EC}$ (2. 2. E.), also $\text{CP}^2=\text{EC}^2-\text{PE.E}p$ (6. 2. E.), therefore $\text{EC}^2-\text{HE.EC}=\text{EC}^2-\text{PE.E}p$, and $\text{HE.EC}=\text{PE.E}p$.

COR. 2. The rectangle contained by PH and Hp is equal to the rectangle contained by HE and HC.

For $\text{HC}^2=\text{CP}^2-\text{PH.H}p$ (5. 2. E.) also $\text{HC}^2=\text{EC.HC}-\text{EH.HC}=\text{CP}^2-\text{EH.HC}$ (3. 2. E. and by the Prop.), therefore $\text{CP}^2-\text{PH.H}p=\text{CP}^2-\text{EH.HC}$, and $\text{PH.H}p=\text{EH.HC}$.

Hyperbola.

Prop. XV.

If a tangent to an hyperbola meet the conjugate axis, and from the points of contact a perpendicular be drawn to that axis, the semi-axis will be a mean proportional between the segments of the axis intercepted between the centre and the perpendicular, and between the centre and the tangent.

Fig. 43. Let DH, a tangent to the hyperbola at D, meet the conjugate axis B*b* in H, and let DG be perpendicular to that axis, then CG : CB : : CB : CH.

Let DH meet the transverse axis in K, draw DE perpendicular to that axis, draw DF, D*f* to the foci, and describe a circle about the triangle D*f*F : the conjugate axis will evidently pass through the centre of the circle, and because the angle FD*f* is bisected by the tangent DK, the line DK will pass through one extremity of that diameter which cuts F*f* at right angles; therefore the circle passes through H. Draw DL to the other extremity of the diameter. The triangles LGD, KCH are similar, for each is similar to the right-angled triangle LDH, therefore LG : GD (=CE) : : CK : CH; hence $LG.CH = CE.CK = CA^2$ (by last Prop.) Now $LC.CH = CF^2$ (35. 3. E.) therefore $LC.CH - LG.CH = CF^2 - CA^2$, that is, $CG.CH = CB^2$ (Def. 10.) wherefore CG : CB : : CB : CH.

Definition.

Fig. 44. 15. If through A, one of the vertices of the transverse axis, a straight line HA*h* be drawn, equal and parallel to B*b*, the conjugate axis, and bisected at A by the transverse axis, the straight lines CHM, C*h m*, drawn through the centre and the extremities of that parallel, are called *Asymptotes.*

Cor. 1. The asymptotes are common to both branches of the hyperbola. Through *a*, the other extremity of the axis, draw H′*ah*′, parallel to B*b*, and meeting the asymptotes of the branch DAD in H′ and *h*′. Because *a*C is equal to AC, *a*H′ is equal to A*h*, or to BC; also *ah*′ is equal to AH, or to BC; hence, by the definition, CH′ and C*h*′ are asymptotes to the opposite branch *d a d*.

Cor. 2. The asymptotes are diagonals of a rectangle formed by drawing perpendiculars to the axes at their vertices. For the lines AH, CB, *a*H′ being equal and parallel, the points H, B, H′ are in a straight line passing through B parallel to A*a*; the same is true of the points *h*, *h*, *h*′.

Prop. XVI.

The asymptotes do not meet the hyperbola; and if from any point in the curve a straight line be drawn parallel to the conjugate axis, and terminated by the asymptotes, the rectangle contained by its segments from that point is equal to the square of half that axis.

Fig. 45. Through D, any point in the hyperbola, draw a straight line parallel to the conjugate axis, meeting the transverse axis in E, and the asymptotes in M and *m*; the points M and *m* shall be without the hyperbola, and the rectangle MD.D*m* is equal to the square of BC. Draw DG perpendicular to B*b*, the conjugate axis: let a tangent to the curve at D meet the transverse and conjugate axis in K and L, and let a perpendicular at the vertex A meet the asymptote in H. Because DK is a tangent, and DE an ordinate to the axis, CA is a mean proportional between CK and CE (14.), and therefore $CK : CE : : CA^2 : CE^2$ (2. Cor. 20. 6. E.) But CK : CE : : LC : LG, and $CA^2 : CE^2 : : AH^2 : EM^2$, therefore $LC : LG : : AH^2 : EM^2$. Again, CB being a mean proportional between CL and CG (15.), $LC : CG : : CB^2 : CG^2$, and therefore $LC : LG : : CB^2 : CB^2 + CG^2$ or $CB^2 + ED^2$; wherefore $AH^2 : EM^2 : : CB^2 : CB^2 + ED^2$. Now $AH^2 = CB^2$ (Def. 15.) therefore $EM^2 = CB^2 + ED^2$, consequently EM^2 is greater than ED^2, and EM greater than ED, therefore M is without the hyperbola. In like manner it appears, that *m* is without the hyperbola, therefore every point in both the asymptotes is without the hyperbola. Again, the straight line M*m*, terminated by the asymptotes, being manifestly bisected by the axis at E, $ME^2 = MD.Dm + DE^2$; but it has been shewn that $ME^2 = BC^2 + DE^2$, therefore $MD.Dm = BC^2$.

Cor. 1. Hence, if in a straight line M*m*, terminated by the asymptotes, and parallel to the conjugate axis, there be taken a point D such, that the rectangle MD.D*m* is equal to the square of that axis, the point D is in the hyperbola.

Cor. 2. If straight lines MD*m*, NR*n* be drawn through D and R, any points in the same branch, or opposite branches of the hyperbola, parallel to the conjugate axis, and meeting the asymptotes in M, *m*, and N, *n*, the rectangles MD.D*m*, NR.R*n* are equal.

Prop. XVII.

The hyperbola, and its asymptote when produced, continually approach to each other, and the distance between them becomes less than any given line.

Take two points E and O in the transverse axis produced, and through these points draw straight lines parallel to the conjugate axis, meeting the hyperbola in D, R, and the asymptotes in M, *m*, and N, *n*. Because NO^2 is greater than ME^2, and $NR.Rn = MD.Dm$ (2. Cor. 16.), therefore $NO^2 - NR.Rn$ is greater than $ME^2 - MD.Dm$, that is, RO^2 is greater than DE^2, and RO is greater than DE; now O*n* is greater than E*m*, therefore R*n* is greater than D*m*, and since R*n* : D*m* : : DM : RN (2. Cor. 16.), DM is greater than RN, therefore the point R is nearer to the asymptote than D; that is, the hyperbola when produced approaches to the asymptote. Let S be any line less than half the conjugate axis, then because D*m*, a straight line drawn from a point in the hyperbola, parallel to the conjugate axis, and terminated by the asymptote on the other side of the transverse axis, may evidently be of any magnitude greater than A*h*, which is equal to half the conjugate axis, D*m* may be a third proportional to S and BC; and since D*m* is also a third proportional to DM, (the segment between D and the other asymptote), and BC, DM may be equal to S; but the distance of D from the asymptote is less then DM; therefore that distance may become less than S; and consequently less than any given line. Fig. 45.

Cor. Every straight line passing through the centre, within those angles contained by the asymptotes through which the transverse axis passes, meets the hyperbola, and therefore is a transverse diameter; and every straight line passing through the centre within the adjacent angles falls entirely without the hyperbola.

Scholium.

The name asymptote (*non concurrentes*) has been given to the line CH, C*h*, because of the property they have of continually approaching to the hyperbola without meeting it, as has been proved in this Proposition.

Hyperbola.

Prop. XVIII.

If from two points in the same branch, or opposite branches of an hyperbola, two parallel straight lines be drawn to meet the asymptotes, the rectangles contained by their segments between the points and the asymptotes are equal.

Fig. 46. Nos. 1, 2. Let D and G be two points in the same branch, or in opposite branches of the hyperbola, and let parallel lines EDe, HGh be drawn to meet the asymptotes in E and e, and H, h; the rectangles $ED.De$, $HG.Gh$ are equal. Through D and G draw straight lines parallel to the conjugate axis, meeting the asymptotes in the points L, l, and M, m. The triangles HGM, EDL are similar; as also the triangles hGm, eDl; therefore $DL : DE :: GM : GH$, and $Dl : De :: Gm : Gh$, hence, taking the rectangles of the corresponding terms of the proportions, $LD.Dl : ED.De :: MG.Gm : HG.Gh$. But $LD.Dl = MG.Gm$ (2 Cor. 16.), therefore $ED.De = HG.Gh$.

Cor. 1. If a straight line be drawn through D, d, two points in the same branch, or opposite branches, the segments DE, de between these points and the asymptotes are equal. For in the same manner that the rectangles $ED.De$, $HG.Gh$ have been proved to be equal, it may be shewn that the rectangles $Ed.de$, $HG.Gh$ are equal, therefore $ED.De = Ed.de$. Let Ee be bisected in O; then $ED.De = EO^2 - OD^2$, and $Ed.de = EO^2 - Od^2$, therefore $EO^2 - OD^2 = EO^2 - Od^2$; hence $OD = Od$, and $ED = ed$.

Cor. 2. When the points D and d are in the same branch, by supposing them to approach till they coincide at P, the line Ee will thus become a tangent to the curve at P. Therefore any tangent KPk, which is terminated by the asymptotes, is bisected at P, the point of contact.

Cor. 3. And if any straight line KPk, limited by the asymptotes, be bisected at P, a point in the curve, that line is a tangent at P. For it is evident that only one line can be drawn through P, which shall be limited by the asymptotes, and bisected at P.

Cor. 4. If a straight line be drawn through D, any point in the hyperbola, parallel to a tangent KPk, and terminated by the asymptotes at E, and e, the rectangle $ED.De$ is equal to the square of PK, the segment of the tangent between the point of contact and either asymptote. The demonstration is the same as in the Proposition.

Cor. 5. If from any point D in a hyperbola, a straight line be drawn parallel to Pp any diameter, meeting the asymptotes in E and e; the rectangle $ED.De$ is equal to the square of half the diameter. The demonstration is the same as in the Proposition.

Prop. XIX.

If two straight lines be drawn from any point in an hyperbola to the asymptotes, and from any other point in the same branch, or opposite branches, two other lines be drawn parallel to the former, the rectangle contained by the first two lines will be equal to the rectangle contained by the other two lines.

Fig. 47. From D, any point in the hyperbola, draw DH and DK to the asymptotes; and from any other point d, draw dh and dk parallel to DH and DK. The rectangles $HD.DK$, $hd.dk$ are equal. Join D, d, meeting the asymptotes in E and e. From similar triangles $ED : DH :: Ed : dh$, and $eD : DK :: ed : dk$, therefore taking the rectangles of the corresponding terms $ED.De : HD.DK :: Ed.de : hd.dk$; but $ED.De = Ed.de$ (18.), therefore $HD.DK = hd.dk$.

Cor. 1. If the lines $D'K'$, $D'H'$, $d'k'$, $d'h'$, be parallel to the asymptotes, and thus form the parallelograms $D'K'CH'$, $d'k'Ch'$, these are equal to one another (16. and 14. 6. E.) And if $D'C$, $d'C$ be joined, the halves of the parallelograms, or the triangles $D'K'C$, $d'k'C$ are also equal.

Cor. 2. If from D', d', any two points in an hyperbola, straight lines $D'K'$, $d'k'$ be drawn parallel to one asymptote, meeting the other in K' and k', these lines are to each other reciprocally as their distances from the centre, or $D'K' : d'k' :: Ck' : CK'$. This appears from last Cor. and 14. 6. E.

Definitions.

16. If Aa be the transverse axis, and Bb the conjugate axis, of an hyperbola DAD, dad; and if Bb be the transverse axis, and Aa the conjugate axis of another hyperbola EBE, ebe, these hyperbolas are said to be conjugate to each other. Fig. 48.

Cor. The asymptotes of the branches DAD, dad of the one hyperbola, are also the asymptotes of the branches EBE, ebe of the other hyperbola. This is evident from Cor. 2. Def. 14.

17. Any diameter of either of the conjugate hyperbolas, is called *a second diameter of the other hyperbola.*

Cor. Every straight line passing through the centre, within the angle through which the conjugate or second axis passes, is a second diameter of the hyperbola.

18. Any straight line not passing through the centre, but terminated both ways by the opposite branches, and bisected by a second diameter, is called an *Ordinate to that diameter.*

Prop. XX.

Any straight line not passing through the centre, but terminated by the opposite branches, and parallel to a tangent to either of the conjugate hyperbolas, is bisected by the second diameter that passes through the point of contact, or is an ordinate to that diameter.

The straight line Dd, terminated by the opposite branches, and parallel to the tangent KQk, is bisected at E by Qq, the diameter that passes through the point of contact. Fig. 49.

Let Dd meet the asymptotes in G and g, and let the tangent meet them in K and k. The straight lines Gg, Kk, are evidently similarly divided in E and Q, and since $KQ = Qk$ (2. Cor. 18.) therefore $GE = Eg$; now $DG = gd$ (2. Cor. 18.) therefore $DE = Ed$.

Cor. 1. Every ordinate to a second diameter is parallel to a tangent at its vertex. The demonstration is the same as in Cor. 2. Prop. 13.

Cor. 2. All the ordinates to the same second diameter are parallel to each other.

Cor. 3. A straight line that bisects two parallel straight lines, which terminate in the opposite branches, is a second diameter.

Cor. 4. The ordinates to the conjugate or second axis are perpendicular to it, and no other second diameter is perpendicular to its ordinates.

Prop. XXI.

If a transverse diameter of an hyperbola be parallel to the ordinates to a second diameter, the latter shall be parallel to the ordinates to the former. Fig. 50.

Hyperbola.

Fig. 50.

Let Pp, a transverse diameter of an hyperbola, be parallel to DEd, any ordinate to the second diameter Qq, the second diameter Qq shall be parallel to the ordinates to the diameter Pp. Draw the diameter dCG through one extremity of the ordinate dD, and join G and D the other extremity, meeting Pp in H. Because dG is bisected at C, and CH is parallel to Dd, the line DG is bisected at H, therefore DG is an ordinate to the diameter Pp. And because dG and dD are bisected at C and E, the diameter Qq is parallel to DG (2. 6. E.) therefore Qq is parallel to any ordinate to the diameter Pp.

Definitions.

19. Two diameters are said to be *conjugate* to one another, when each is parallel to the ordinates to the other diameter.

Cor. Diameters which are conjugate to one another are parallel to tangents at the vertices of each other.

20. A third proportional to any diameter and its conjugate is called the *Parameter,* also the *Latus rectum* of that diameter.

Prop. XXII.

The tangent at the vertex of any transverse diameter of an hyperbola, which is terminated by the asymptotes, is equal to the diameter that is conjugate to that diameter.

Fig. 51.

Let PCp be any transverse diameter of an hyperbola, HPh a tangent at its vertex, meeting the asymptotes in H and h, and Qq the diameter which is conjugate to Pp; the tangent Hh is equal to the diameter Qq. For through D, any point in the hyperbola, draw a straight line parallel to the tangent and diameter, cutting either of the conjugate hyperbolas in d, and the asymptotes in E and e, and through D and d draw lines parallel to Bb the conjugate axis, meeting the asymptotes in the points K, k, and L, l. The triangles DEK, dEL are similar, as also eDk, edl, therefore $KD : DE :: Ld : dE$, and $kD : De :: ld : de$: therefore, taking the rectangles of the corresponding terms, $KD.Dk :: ED.De :: Ld.dl : Ed.de$. But $KD.Dk = BC^2$ (16.) and $BC^2 = Ld.dl$ (5. Cor. 18.) therefore $ED.De = Ed.de$. Now $ED.De = HP^2$ (4. Cor. 18.) and $Ed.de = QC^2$ (5. Cor. 18.) therefore $HP^2 = QC^2$, and $HP = QC$; and consequently $Hh = Qq$.

Cor. 1. If another tangent be drawn to the curve at p, meeting the asymptotes in H' and h', the straight lines which join the points H, H' also h, h' are tangents to the conjugate hyperbolas at Q and q: for pH' as well as PH is equal and parallel to CQ; therefore the points H, Q, H' are in a straight line parallel to Pp, and $HQ = H'Q$ (33. 1. E.) therefore HQH' is a tangent to the curve at Q (3. Cor. 18.) In like manner it appears that hqh' is a tangent at q.

Cor. 2. If tangents be drawn at the vertices of two conjugate diameters, they will meet in the asymptotes, and form a parallelogram, of which the asymptotes are diagonal.

Prop. XXIII.

If a tangent to an hyperbola meet a second diameter, and from the point of contact an ordinate be drawn to that diameter, half the second diameter will be a mean proportional between the segments of the diameter intercepted between the centre and the ordinate, and between the centre and the tangent.

Hyperbola.

Fig. 52.

Let DL a tangent to the curve at D' meet the second diameter Qq in L, and let DGd' be an ordinate to that diameter, then $CG : CQ :: CQ : CL$. For let Pp be the diameter that is conjugate to Qq, let HPh be a tangent at the vertex, terminated by the asymptotes; through D draw the ordinate DEd to the diameter Pp, meeting the asymptotes in M and m; let K be the intersection of DL and Pp. Because DK is a tangent at D, and DEd an ordinate to Pp, CP is a mean proportionl between CE and CK (14.) and therefore $CE^2 : CP^2 :: CE : CK$. Now the lines CQ, PH, EM being parallel (2. Cor. 13.) from similar triangles $CE^2 : CP^2 :: EM^2 : PH^2$, and CE or $DG : CK :: LG : LC$; therefore $EM^2 : PH^2 :: LG : LC$, and by division, &c. $EM^2 - PH^2 : PH^2 :: CG : LC :: CG^2 : CG.LC$. But since $PH^2 = MD.Dm$ (4 Cor. 18.), $EM^2 - PH^2 = ED^2 = CG^2$, therefore $PH^2 = CG.LC$, wherefore, and since $PH = CQ$ (22.) $CG : CQ :: CQ : CL$.

Prop. XXIV.

If an ordinate be drawn to any transverse diameter of an hyperbola, the rectangle contained by the abscissæ of the diameter will be to the square of the semiordinate as the square of the diameter to the square of its conjugate.

Fig. 52.

Let DEd be an ordinate to the transverse diameter Pp, and let Qq be its conjugate diameter, $PE.Ep : DE^2 :: Pp^2 : Qq^2$. Let DKL, a tangent at, D meet the diameter in K, and its conjugate in L. Draw DG parallel to Pp, meeting Qq in G. Because CP is a mean proportional between CE and CK (14.) $CP^2 : CE^2 :: CK : CE$, and by division, $CP^2 : PE.Ep :: CK : KE$. But, because ED is parallel to CL, $CK : KE :: CL : DE$ or CG; and because CQ is a mean proportional between CG and CL (23.) $CL : CG :: CQ^2 : CG^2$, or DE^2, therefore $CP^2 : PE.Ep :: CQ^2 : DE^2$, and by inversion, and alternation, $PE.Ep : DE^2 :: CP^2 : CQ^2 :: Pp^2 : Qq^2$.

Cor. 1. If an ordinate be drawn to any second diameter of an hyperbola, the sum of the squares of half the second diameter, and its segment intercepted by the ordinate from the centre, is to the square of the semiordinate as the square of the second diameter to the square of its conjugate.

Let DG be a semiordinate to the second diameter Qq. It has been shewn that DE^2 or $CG^2 : CQ^2 :: PE.Ep : CP^2$, therefore by composition $CQ^2 + CG^2 : CQ^2 :: CE^2$ or $DG^2 : CP^2$; and by alternation, $CQ^2 + CG^2 : DG^2 :: CQ^2 : CP^2 :: Qq^2 : Pp^2$.

Cor. 2. The squares of semiordinates, and of ordinates to any transverse diameter, are to one another as the rectangles contained by the corresponding abscissæ; and the squares of semiordinates, and of ordinates to any second diameter, are to one another as the sums of the squares of half that diameter, and the segments intercepted by the ordinates from the centre.

Cor. 3. The ordinates to any transverse diameter, which intercept equal segments of that diameter from the centre, are equal to one another, and, conversely, equal ordinates intercept equal segments of the diameter from the centre.

Prop. XXV.

The transverse axis of an hyperbola is the least of all its transverse diameters, and the conjugate axis is the least of all its second diameters.

Hyperbola.

Fig. 53.

Let Rr be the transverse axis, Pp any other transverse diameter, draw PE perpendicular to Rr; then CE being greater than CR, and CP greater than CE, much more is CP greater than CR; therefore Pp is greater than Rr. In like manner it is shewn, that if Ss be the conjugate axis, and Qq any other second diameter, Qq is greater than Ss.

Prop. XXVI.

If an ordinate be drawn to any transverse diameter of an hyperbola, the rectangle contained by the abscissæ of the diameter is to the square of the semiordinate as the diameter to its parameter.

Fig. 54.

Let DE be a semiordinate to the transverse diameter Pp; let PG be the parameter of the diameter, and Qq the conjugate diameter. By the definition of the parameter (Def. 20.) $Pp : Qq :: Qq : PG$, therefore $Pp : PG :: Pp^2 : Qq^2$, (2 Cor. 20. 6. E.) But $Pp^2 : Qq^2 :: PE.Ep : DE^2$, (24.) therefore $PE.Ep : DE^2 :: Pp : PG$.

Cor. Let the parameter PG be perpendicular to the diameter Pp; join pG, and from E draw EM parallel to PG meeting pG in M. The square of DE the semiordinate is equal to the rectangle contained by PE and EM. For $PE.Ep : DE^2 :: Pp : PG$, and $Pp : PG :: Ep : EM :: PE.Ep :: PE.EM$; therefore $DE^2 = PE.EM$.

Scholium.

If the rectangles $PGLp$, HGKM be completed, it will appear that the square of ED is equal to the rectangle MP, which rectangle is greater than the rectangle KP, contained by the abscissa PE and the parameter GP, by a rectangle KH similar, and similarly situated to LP, the rectangle contained by the parameter and diameter. It was on account of the excess of the square of the ordinate above the rectangle contained by the abscissa and parameter that Apollonius gave the curve to which the property belongs the name *Hyperbola*.

Prop. XXVII.

If from the vertices of two conjugate diameters of an hyperbola there be drawn ordinates to any third transverse diameter, the square of the segment of that diameter, intercepted between the ordinate from the vertex of the second diameter, and the centre, is equal to the rectangle contained by the segments between the other ordinate and the vertices of the third transverse diameter. And the square of the segment intercepted between the ordinate from the vertex of the transverse diameter, and the centre, is equal to the square of the segment between the other ordinate and the centre, together with the square of half the third transverse diameter.

Fig. 53.

Let Pp, Qq be two conjugate diameters, of which Pp is a transverse, and Qq a second diameter; let PE, QG be semiordinates to any third transverse diameter Rr, then, $CG^2 = RE.Er$ and $CE^2 = CG^2 + CR^2$. Draw the tangents PH, QK, meeting Rr in H and K. The rectangles HC.CE and KC.CG are equal, for each is equal to CR^2 (14. and 23.) therefore $HC : CK :: CG : CE$. But the triangles HPC, CQK are evidently similar (Cor. to Def. 19.) and since PE, QG are parallel, their bases CH, KC are similarly divided at E and G, therefore $HC : CK :: HE : CG$, wherefore $CG : CE :: HE : CG$, consequently $CG^2 = CE.EH =$ (by 1. Cor. 14.) $RE.Er$. Again, from the similar triangles HPC, CQK, $HC : CK :: CE : KG$. Now it was shewn that $HC : CK :: CG : CE$, therefore $CG : CE :: CE : KG$. consequently $CE^2 = CG.GK =$ (3.2.E.) $CG^2 + GC.CK$, But $GC.CK = CR^2$ (23.) therefore $CE^2 = CG^2 + CR^2$.

Hyperbola.

Cor. 1. Let Ss be the diameter that is conjugate to Rr, then Rr is to Ss as CG to PE, or as CE to QG. For $Rr^2 : Ss^2 :: RE.Er$, or $CG^2 : PE^2$, therefore $Rr : Ss :: CG : PE$. In like manner $Rr : Ss :: CE$ QG.

Cor. 2. The difference between the squares of CE, CG, the segments of the transverse diameter to which the semiordinates PE, QG are drawn, is equal to the square of CR, the semidiameter. For it has been shewn that $CE^2 = CG^2 + CR^2$; therefore $CE^2 - CG^2 = CR^2$.

Cor. 3. The difference of the squares of any two conjugate diameters is equal to the difference of the squares of the axes. Let Rr, Ss be the axes, and Pp, Qq any two conjugate diameters; draw PE, QG perpendicular to Rr, and PL, QM perpendicular to Ss. Then $CE^2 - CG^2 = CR^2$, and $CM^2 - CL^2$, or $GQ^2 - PE^2 = CS^2$, therefore $CE^2 + PE^2 - (CG^2 + GQ^2) = CR^2 - CS^2$, that is (47. 1. E.) $CP^2 - CQ^2 = CR^2 - CS^2$, therefore $Pp^2 - Qq^2 = Rr^2 - Ss^2$.

Prop. XXVIII.

If four straight lines touching conjugate hyperbolas at the vertices of any two conjugate diameters, the parallelogram formed by them is equal to the rectangle contained by the transverse and conjugate axis.

Let Pp, Qq be any two conjugate diameters, a parallelogram DEGH formed by tangents to the conjugate hyperbolas at their vertices is equal to the rectangle contained by Aa, Bb, the two axes. Fig. 55.

Let Aa, one of the axes, meet the tangent PE in K; join QK, and draw PL, QM perpendicular to Aa. Because $CK : CA : CA : CL$ (14.) and $CA : CB :: CL : QM$ (1. Cor. 26.) ex æq. $CK : CB :: CA : QM$; therefore $CK.QM = CB.CA$. But $CK.QM =$ twice the trian. CKQ=paral. CPEQ; therefore the paral. CPEQ $= CB.CA$; and, taking the quadruples, the parallelogram DEGH is equal to the rectangle contained by Aa and Bb.

Prop. XXIX.

If two tangents at the vertices of any transverse diameter of an hyperbola meet a third tangent, the rectangle contained by their segments between the points of contact, and the points of intersection, is equal to the square of the semidiameter to which they are parallel. And the rectangle contained by the segments of the third tangent between its point of contact and the parallel tangents, is equal to the square of the semidiameter to which it is parallel.

Let PH, ph, tangents at the vertices of a transverse diameter Pp, meet DHh, a tangent to the curve, at any point D, in H and h; let CQ be the semidiameter to which the tangents PH, ph are parallel, and CR that to which Hh is parallel; then $PH.ph = CQ^2$, and $DH.Dh = CR^2$; let Hh meet the semidiameters CP, CQ in L and K. Draw DE, RM parallel to CQ, and DG parallel to CP. Because $LP.Lp = LE.LC$ (2. Cor. 14.), $LP : LE :: LC : Lp$; hence, and because of the parallels PH, ED, CK, ph, $PH : ED :: CK : ph$, wherefore $PH.ph = ED.CK$. But $ED.CK = CG.CK = CQ^2$ (23.), therefore $PH.ph = CQ^2$. Again, the triangles LED, CMR are evidently similar, and Fig. 56.

Hyperbola.

LE, LD are similarly divided at P and H, also at p and h, therefore PE : HD : : (LE : LD) CM : CR, also pE : hD : : (LE : LD : :) CM : CR, hence taking the rectangles of the corresponding terms, PE.pE : HD.hD : : $CM^2 : CR^2$. But if C, D be joined, the points D and R are evidently the vertices of two conjugate diameters (Cor. to Def. 19.), and therefore PE.pE=CM^2 (27.), therefore HD.hD=CR^2.

Cor. The rectangle contained by LD and DK, the segments of a tangent intercepted between D, the point of contact, and Pp, Qq, any two conjugate diameters, is equal to the square of CR, the semidiameter to which the tangent is parallel.

Let the parallel tangents PH, $p\,h$, meet LK in H and h, and draw DE a semiordinate to Pp. Because of the parallels ED, PH, CK, ph, LE : LD : : EP : DH, and EC : DK : : Ep : Dh, therefore LE.EC : LD.DK : : EP.Ep : DH.Dh. But LE.EC=EP.Ep (1. Cor. 14.), therefore LD.DK=DH.Dh= (by this Prop.) CR^2.

Prop. XXX.

If two straight lines be drawn from the foci of an hyperbola perpendicular to a tangent, straight lines drawn from the centre, to the points in which they meet the tangents, will each be equal to half the transverse axis.

Fig. 57. Let PdD be a tangent to the curve at P, and FD, fd perpendiculars to the tangent from the foci, the straight lines joining the points C, D and C, d are each equal to AC, half the transverse axis. Join FP, fP, and produce FD, Pf till they intersect in E. The triangles FDP, EDP have the angles at D right angles, and the angles FPD, EPD equal (8.), and the side DP common to both; they are therefore equal, and consequently have ED=DF, and EP=PF, wherefore Ef=FP—Pf=Aa. Now, the straight lines FE, Ff being bisected at D and C, the line DC is parallel to Ef, (2. 6. E.) and thus the triangles FfE, FCD are similar, therefore Ff:fE, or Aa : : FC : CD: but FC is half Ff, therefore CD is half of Aa.

Cor. If a straight line Qq be drawn through the centre parallel to the tangent Dd, it will cut off from PF, Pf the segments PG, Pg, each equal to AC, half the transverse axis. For CdPG, CDPg are parallelograms, therefore PG=dC=AC, and Pg=DC=AC.

Prop. XXXI.

The rectangle contained by perpendiculars drawn from the foci of an hyperbola to a tangent, is equal to the square of half the conjugate axis.

Fig. 57. Let PdD be a tangent, and FD, fd perpendiculars from the foci, the rectangle contained by FD and fd is equal to the square of BC, half the conjugate axis.

It is evident from the last Proposition, that the points D, d are in the circumference of a circle, having the same centre as the hyperbola, and radius CA half the transverse axis. Now, FDd being a right angle, if dC be joined, and produced, it will meet DF in H, a point in the circumference (31. 3. E.); and since FC=fC, and CH=Cd, and the angles FCH, fCd are equal, FH is equal to fd, therefore DF.df=DF.FH=AF.aF (Cor. 36. 3. E.)=CB^2 (3.)

Cor. If PF, Pf be drawn from the point of contact to the foci, the square of FD is a fourth proportional to fP, FP, and CB^2. For the angles fPd, FPD are equal (8.), and FDP, fdP are right angles, therefore the triangles FDP, fdP are similar, and fP : FP : : fd : FD : : fd.FD or $BC^2 : FD^2$.

Prop. XXXII.

If from C, the centre of an hyperbola, a straight line CL be drawn perpendicular to a tangent LD, and from D, the point of contact, a perpendicular be drawn to the tangent, meeting the transverse axis in H, and the conjugate axis in h, the rectangle contained by CL and DH is equal to the square of CB, the semiconjugate axis; and the rectangle contained by CL and Dh is equal to the square of CA, the semitransverse axis. Fig. 58.

Let the axes meet the tangent in M and m, and from D draw the semiordinates DE, De, which will be perpendicular to the axes. The triangles DEH, CLm are evidently equiangular, therefore DH : DE : : Cm : CL, hence CL.DH=DE.Cm, but DE.Cm or Ce.Cm=BC^2 (15.), therefore CL.DH=BC^2. In the same way it is shewn that CL.Dh=AC^2.

Cor. 1. If a perpendicular be drawn to a tangent at the point of contact, the segments intercepted between the point of contact and the axes are to each other reciprocally as the squares of the axes by which they are terminated. For $AC^2 : BC^2$: CL.Dh : CL.DH : : Dh : DH.

Cor. 2. If DF be drawn to either focus, and HK be drawn perpendicular to DF, the straight line DK shall be equal to half the parameter of the transverse axis. Draw CG parallel to the tangent at D, meeting DH in N, and DF in G. The triangles GDN, HDK are similar, therefore GD : DN : : HD : DK; and hence GD.DK=HD.DN. But GD=AC (Cor. 30.) and ND=CL, therefore AC.DK=HD.CL= (by the Prop.) CB^2, wherefore AC : BC : : BC : DK, hence DK is half the parameter of Aa, (Def. 20.)

Prop. XXXIII.

If through P and Q, the vertices of two semidiameters of an hyperbola, there be drawn straight lines PD, QE parallel to one of the asymptotes CM, meeting the other asymptote in D and E, the hyperbolic sector PCQ is equal to the hyperbolic trapezium PDEQ. Fig. 59.

Let CQ meet PD in T, the triangles CDP, CEQ are equal (1. Cor. 19.); therefore, taking the triangle CDT from both, the triangle CTP is equal to the quadrilateral DEQT: to these add the figure PTQ, and the hyperbolic sector PCQ is equal to the hyperbolic trapezium PDEQ.

Prop. XXXIV.

If from the centre of an hyperbola the segments CD, CE, CH be taken in continued proportion in one of the asymptotes, and the straight lines DP, EQ, HR be drawn parallel to the other asymptote, meeting the hyperbola in P, Q, R; the hyperbolic areas PDEQ, QEHR are equal. Fig. 59.

Through Q draw a tangent to the curve, meeting the asymptotes in K and L; join PR, meeting the asymptotes in M and N; draw the semidiameters CP, CQ, CR; let CQ meet PR in G. Because QE is parallel to CM, and KQ is equal to QL (2. Cor. 18.), CE is equal to EL; and because MC, PD, RH are parallel, and MP is equal to RN (1. Cor. 18.), CD is equal to HN. Now, by hypothesis, CD : CE : : CE : CH, therefore NH : LE : : CE : CH; but CE : CH : : HR : EQ

Hyperbola.

(2. Cor. 19.), therefore NH : LE : : HR : EQ, and by alternation, NH : HR : : LE : EQ. Now the angles at H and E are equal, therefore the triangles NHR, LEQ are equiangular, and NR is parallel to LQ; consequently, RP is an ordinate to the diameter CQ (13.), and is bisected by it at G; and as CQ bisects all lines which are parallel to KL, and are terminated by the hyperbola, it will bisect the area PQR. Let the equal areas PQG, RQG be taken from the equal triangles PCG, RCG, and there will remain the hyperbolic sectors PCQ, RCQ equal to each other. Therefore (33.) the areas DPQE, EQRH are also equal.

Cor. Hence, if CD, CE, CH, &c. any number of segments of the asymptote be taken in continued proportion, the areas DPQE, DPQRH, &c. reckoned from the first line DP, will be in arithmetical progression.

Prop. XXXV. *Problem.*

An hyperbola being given by position, to find its axes.

Fig. 60.

Let H*A*h be the given hyperbola. Draw two parallel straight lines Hh, Kk, terminating in either of the opposite branches, and bisect them at L and M; join LM, and produce it to meet the hyperbola in P; then LP will be a transverse diameter (4. Cor. 13.) Let p be the point in which it meets the opposite branch, bisect Pp in C; the point C is the centre (9.) Take D, any point in the hyperbola, and on C as a centre, with the distance CD, describe a circle; if this circle be wholly without the opposite branches of the hyperbola, then CD must be half the transverse axis (25.); but if not, let the circle meet the hyperbola again in d, join Dd, and bisect it in E, join CE meeting the opposite branches in A and a; then Aa will be the transverse axis (5. Cor. 13.), for it is perpendicular to Dd (3. 3. E.), which is an ordinate to Aa. The other axis will be found, by drawing Bb a straight line through the centre perpendicular to Aa, and taking CB so, that CB^2 may be a fourth proportional to the rectangle AE.Ea, and the squares of DE and CA, thus CB is half the conjugate axis, (24.)

SECTION IV.

Of the Parabola.

Definitions.

Fig. 61.

1. Let PQ be a straight line given by position, and F a given point without it, and let a point D move in their plane, in such a manner that DF, its distance from the given point, is equal to DE, its distance from the given line; the point D will describe a curve line, called a *Parabola.*

2. The straight line PQ is called the *Directrix.*

3. The given point F is called the *Focus.*

Corollaries to Def. 1, 2, and 3. If a straight line FP be drawn through the focus perpendicular to the directrix at P, the parabola passes through A, the middle of FP, and it cannot meet the perpendicular FP in any other point.

2. If MFm be drawn perpendicular to FP, and FM and Fm be each taken equal to FP, the parabola will pass through M and m, and through no other points in the line Mm.

Parabola.

Def. 4. The straight line AF produced indefinitely, is called the *Axis.*

5. The point A, in which the axis meets the curve, is called the *Vertex.*

Scholium.

Fig. 61.

From the definition of the curve, we have the following method of describing it mechanically. Place the edge of a fixed ruler along PQ the directrix, and to this edge apply another moveable ruler, LEG, of any length which is so constructed that one of its sides EG is always perpendicular to EQ. Fasten one end of a string equal in length to GE at G the end of this ruler, and the other at F the focus; and pull the string tight by passing it round a pin D, which slides along GE. If the moveable ruler be now made to slide along the fixed ruler, and the pin D along the line EG, so as to keep the string always extended into the two straight lines GD, DF, it is evident that the pin will trace the parabola.

Prop. I.

Fig. 62.

If a circle be described on F the focus as a centre, with a radius equal to FP its distance from the directrix; and from any point D in the parabola a straight line be drawn to the focus and produced to meet the circle in I, and IN be drawn perpendicular to the axis; the rectangle FD.PN is equal to the constant space PF^2.

Draw DE perpendicular to the directrix, and join EF, PI. The triangles EDF, PFI are similar (6. 6. E.) for ED=DF, (Def. 1.) and PF=FI, and the angles EDF, PFI are equal (29. 1. E.) therefore FE is parallel to PI (28. 1.) The triangles FPE, PNI are also equiangular; for the angles at P and N are right angles, and the angles EFP, NPI are equal (29. 1. E.) Hence DF : FE : : IF : IP; and FE : FP : : IP : PN (4. 6. E.) therefore, ex æq. DF : FP : : IF : PN (22. 5. E.) and $DF.PN=FP.FI=FP^2$ (16. 6. E.)

Cor. Hence the point in which a line drawn from the focus meets the curve may be found, viz. by taking FD a third proportional to PN and FP.

Scholium.

From this Proposition we learn what is the figure of the curve, by considering the change that takes place in the magnitude of the line FD, corresponding to a change in its position. When FD has the position FA, the points I and N are at L, and as in this case PN, one side of the constant rectangle FD.PN is the greatest possible; the other side FD must be the least. Suppose now FD to depart from the position FA, and to revolve about F; then, as the angle PFD, or IFL increases, the point N will approach to P, and as PN one side of the rectangle FD.PN now decreases until it vanishes, FD its other side must increase; and go on increasing until it has attained a magnitude greater than any that can be assigned. In general, we may conclude,

1. That the parabola is a continuous curve, which passes through A the middle of FP, and extends to an indefinite distance from the focus on both sides of the axis.

2. That every line which can be drawn from the focus will, if produced, terminate in the curve, with the exception of FX the prolongation of FA; and that the least will be FA, and of the others, those nearer the least will be less than those more remote.

Parabola.

3. That lines drawn from the focus at equal angles with the axis on opposite sides of it, and terminating in the curve, are equal to one another.

Definition.

6. A straight line which meets a parabola, and being produced does not cut it, is said to *touch* the curve, and is called a *Tangent.*

PROP. II. *Problem.*

Having given the focus, and directrix, and consequently the axis, to find the points in which a straight line perpendicular to the axis meets the curve.

Fig. 63. Let RS, the line given by position, meet the axis in G, on the focus F as a centre, with a radius equal to PG, the distance of the line from the directrix, describe a circle to meet the line in D and d, which will be points in the parabola.

For draw DE, de perpendicular to the directrix, then DE=PG=DF, and de=PG=dF; therefore D and d are points in the parabola. (Def. 1.)

The construction of the problem requires that FG should not exceed FD, that is PG; but this condition will manifestly be fulfilled if G be any where in AX the prolongation of PA, and it would not be fulfilled if G were between P and A: Therefore the line given by position must not be nearer to the directrix than to the focus.

COR. 1. Every straight line perpendicular to the axis that does not pass through the vertex meets the curve in two points, and no more; if it pass through the vertex, it will meet the curve in one point only, and if it be nearer to the directrix than to the focus, it will not meet the curve at all.

COR. 2. Every chord perpendicular to the axis is bisected by the axis.

COR. 3. A perpendicular to the axis at the vertex is a tangent.

PROP. III. *Problem.*

Having the focus and directrix, and consequently the axis, to find the point in which a line parallel to the axis meets the parabola.

Fig. 64. Let ER, the line given by position, meet the directrix in E. Draw FE to the focus, and bisect EF at O, by a perpendicular OT; and because PER is a right angle, the angle OER is not a right angle, and therefore the lines ER, OT will meet at a point D, which will be a point in the parabola. For the triangles FOD, EOD are manifestly in all respects equal (4. 1. E.), therefore DF=DE; and hence D is a point in the parabola (Def. 1.)

COR. Every straight line parallel to the axis meets the parabola in one point and no more. For besides D, no other point can be found in ER that is equally distant from E and F.

PROP. IV.

Fig. 65. If from any point Q in the directrix a straight line be drawn to meet the parabola in D, and LF l a parallel to the directrix through the focus in H; and if another straight line be drawn to D from the focus, a perpendicular QK, drawn to this last line from Q, shall be equal to FH, the segment cut off by the former from the line FL.

Draw DE perpendicular to the directrix, and produce DF to meet it in I. The triangles DFH, DIQ are manifestly equiangular (29. 1. E.) as also the triangles IED, IKQ (32. 1. E.) therefore, DF : FH (:: DI : IQ) :: DE : QK; but DF=DE, (Def. 1.) therefore FH=QK.

Parabola.

COR. 1. If the lines FD, QH have such a position that FH is equal to QK the perpendicular drawn from Q to FD; then if FD and QH are not parallel, they will meet at D, a point in the parabola.

COR. 2. If QF be drawn to the focus, and in LF l, which is parallel to the directrix, there be taken FL, and F l each equal to FQ, then, any straight line drawn from Q to meet the parabola will either pass through the points L, l, or between these points. For QK cannot exceed QF, therefore FH cannot exceed FL.

COR. 3. Any straight line drawn from Q, to pass beyond the limits L l will be entirely without the parabola.

PROP. V. *Problem.*

The focus and directrix being given, to find the points in which a straight line not perpendicular to the axis meets the curve.

CASE 1. Let the line given by position be XY, which passes through F the focus. Draw FQ perpendicular to XY, meeting the directrix in Q, and in a line passing through F, parallel to the directrix, take FL and F l each equal to FQ; and join QL, Q l, then as the angles FQL, FQ l cannot be right angles (5. and 17. 1. E.) the lines QL, Q l must meet XY in two points D, d, which will be in the parabola. (Cor. 1.) Fig. 66.

CASE 2. Next, let the line given by position meet the directrix in Q (Fig. 67.) and the parallel LF l in H, so that FL and F l being taken each equal to FQ, the point H may fall between L and l. On Q as a centre, with a radius equal to FH, (which is less than FL or FQ,) describe a circle; draw FK, F k tangents to that circle at K and k; and if neither of these is parallel to QH, they will meet it in D, d, which will be two points in the parabola, as is evident from Cor. 1. Prop. 4. by joining QK, Q k. Fig. 67.

If one of the lines, as F k, were parallel to QD, so that there was only one intersection, then as FH=Q k, the figure kQHF would, in that case, be a rectangle, and so QH would be perpendicular to FL, or parallel to the axis, a conclusion which agrees with what has been already shewn in Prop. 3.

CASE 3. Lastly, let the line Q l, given by position, pass through l, either of the two points L, l, determined as above. Draw FD′ perpendicular to FQ, and because FQ l is not a right angle (7. 6. and 17. 1. E.) the lines Q l, FD′ must meet, and D′, their intersection, is a point in the parabola (1. Cor. 4.)

COR. 1. The points L, l being supposed determined as in the proposition, every straight line drawn from Q to pass between L and l, either meets the curve in one point only, or in two points and no more; for the number of intersections cannot exceed the number of tangents to the circle, as has been explained in Sect. II. Prop. 7.

COR. 2. A straight line drawn from Q, through L, or l, meets the curve in one point only, and is a tangent. The reason is the same as has been given in the like case of Prop. 7. Sect. II.

COR. 3. Every straight line which meets a parabola cuts it in one point only, or in two points, and no more, or it touches it, and these are all the varieties that can happen.

COR. 4. If two lines FD, FQ, which contain a right angle at the focus, meet the curve in D, and the di-

Parabola. rectrix in Q; a line joining Q and D shall be a tangent at D; and only one tangent can be drawn at that point. It is evident from Case 3, and Corollary 3, that DQ is a tangent; and to prove that no other can be drawn at D; (Fig. 68.) draw DHQ′ any other line, meeting the directrix, and its parallel in Q′ and H′; draw QK perpendicular to FD, and take FL=FQ′; then, because FH=Q′K (4.) and FL=Q′F (by construction) therefore FH is less than FL; hence the line Q′D cuts the parabola, as appears from the first corollary.

Fig. 68.

Cor. 5. Tangents drawn at the extremities of a chord passing through the focus, meet in the directrix, and form a right angle; and a perpendicular to the chord at the focus meets the directrix, at their intersection. See Fig. 66.

Prop. VI.

A tangent to a parabola makes equal angles with a straight line drawn from the point of contact to the focus, and another perpendicular to the directrix.

Fig. 69. If the tangent be at the extremity of the axis, the truth of the proposition is evident from Cor. 3. Prop. 2. If it have any other position, as DQ, let it meet the directrix in Q, and draw DF to the focus, and DE perpendicular to the directrix; And because FD=DE and QD is common to the triangles QFD, QED, and the angles at F and E are right angles (by Hyp. and 4. Cor. 5.) the triangles are in all respects equal (47. and 8. 1. E.) hence the angles QDE, QDF are equal.

Cor. 1. The straight line FE, which joins the points F and E, is perpendicular to the tangent, and is bisected by it. For the triangles DEI, DFI, are evidently equal in all respects (4. 1. E.)

Cor. 2. Every tangent, except that at the vertex, meets the directrix at an oblique angle.

Definition.

7. A straight line parallel to the axis, which terminates at one extremity in the parabola, and lies entirely within it, is called a *diameter*, and the point in which it meets the curve is called its *vertex*.

Prop. VII.

A straight line drawn from the focus of a parabola to the intersection of two tangents, makes equal angles with straight lines drawn from the focus to the points of contact.

Fig. 70. Let tangents to a parabola at D and *d* intersect each other at H; draw DF, *d* F, HF, to the focus; the lines DF, *d* F make equal angles with HF.

Draw DE, *de* perpendicular to the directrix, and join HE, H*e*. The triangles HDE, HDF are in all respects equal, (4. 1. E.) for they have DE = DF, and DH common to both; and the angles at D equal; therefore HE=HF, and the angle HED is equal to HFD. In the same way it may be proved, that the triangles H *d e*, H *d*F are equal, and consequently that HF=H*e*, and the angle HF *d* to the angle H *e d*; but HE being equal to H *e*, for each has been proved equal to HF, the angles HE *e*, H *e* E are equal, (5. 1. E.) and adding the right angles *e*ED, E *ed*; the angles HED, H *e d* are equal; but these have been proved equal to HFD, HF *d*, therefore the line HF makes equal angles with FD, F *d*.

Cor. 1. Perpendiculars drawn from the intersection of two tangents to lines drawn from the focus through the points of contact, are equal. For HI, H *i*, being drawn perpendicular to DF, *d*F; the triangles HFI, HF *i* are manifestly equal (26. 1. E) and therefore HI=H *i*. Parabola.

Cor. 2. Perpendiculars from the intersection of two tangents to diameters passing through the points of contact are equal.

Draw GH *g* through H perpendicular to DG, *dg*; and because the triangles HDG, HDI have HD common to both, the angles at D equal, and the angles at G and I right angles, they are in all respects equal, (26. 1. E.) and HG=HI; in like manner it appears that H *g*=H *i*; but HI = H *i*, therefore HG=H*g*.

Cor. 3. If a straight line HF be drawn to the focus, from the intersection of two tangents HD, H *d*, and another HK be drawn perpendicular to the directrix; these will make equal angles with the tangents.

The triangles EHK, *e*HK are equiangular (32. 1. E.) for the angles at K are right angles, and the angles at E and *e* equal (5. 1. E.) therefore the angles EHK, *e* HK are equal; but EHK=EHD+DHK=DHF+DHK = FHK+2 DHF; and *e* HK=*e*H *d*+*d* HK=*d* HF+*d* HK=FHK+2*d*HK, therefore FHK+2DHF =FHK +2 *d* HK, and 2 DHF =2 *d* HK, or DHF= *d* HK.

Prop. VIII.

If two tangents be at the extremities of a chord, and a third tangent be parallel to the chord, the part of this tangent intercepted between the other two is bisected at the point of contact.

Let HD, H *d* be tangents at the extremities of the chord D*d*, and K *p k* a tangent parallel to the chord, meeting the others in K and *k*; the line K *k* is bisected at P, the point of contact. From the intersection of each two tangents, draw perpendiculars upon the diameters passing through their points of contact, that is, draw HI, H *i* perpendicular to the diameters DL, *d l*, and KM, K *m* perpendicular to the diameters DL, PE, and *k*N, *k n* perpendicular to the diameters *d l*, PE. Fig. 71.

The triangles DHI, DKM are manifestly equiangular, as also the triangles *d* H *i*, *d k* N; therefore HD : DK :: HI : KM, and H *d* : *d k* :: H *i* : *k* N, (4. 6. E.) but because K*k* is parallel to D*d*, HD : DK :: H*d* : *dk* (2. 6. E.) therefore HI : KM :: H *i* : *k* N, now HI=H *i* (2. Cor. 7.) therefore KM=*k* N; but KM=K *m*, and KN=*k n* (2 Cor. 7.) therefore K *m*=*k n*, and since we have manifestly K *m* : *k n* : : KP : *k* P (4. 6. E.) therefore KP=*k* P.

Definitions.

8. Any chord that is bisected by a diameter is called an *ordinate* to that diameter.

9. The segment of a diameter between its vertex and an ordinate is called an *abscissa*.

Prop. IX.

Any chord parallel to a tangent, is bisected by the diameter which passes through the point of contact, or is an ordinate to that diameter.

The chord D*d*, which is parallel to the tangent KP*k*, is bisected at E by PE, the diameter that passes through P, the point of contact. For, let HD, H*d*, be tangents, and DN, D*n* diameters at the extremities of the chord, and let the tangent at P meet the former in K, *k*, and the latter in L, *l*; also through H draw OH*o* parallel- Fig. 72.

Parabola. lel to Dd; and IHi perpendicular to the diameters DN, dn. The triangles DKL, DHO, are manifestly similar, as also the triangles dkl, dHo, and the triangles IHO, iHo; therefore, DK : DH :: KL : HO, and dk : dH :: kl : Ho; (4. 6. E.) but because Kk is parallel to Dd, DK : DH :: dk : dH (2. 6. E.), therefore, KL : HO :: kl : Ho; but HO : HI :: Ho : Hi; therefore ex æquali KL : HI :: kl : Hi (22. 5. E.), but HI = Hi (2. Cor. 7.), therefore KL = kl, now KP = kP (8.), therefore PL = Pl, and (34. 1. E.) ED = Ed.

Cor. 1. Straight lines which touch a parabola at the extremities of an ordinate to a diameter, intersect each other in that diameter; for Kk and Dd being bisected at P and E, the points H, P, E, lie in a straight line, (Lemma to Prop. 13. Sect. II.)

Cor. 2. Every ordinate to a diameter is parallel to a tangent at its vertex; for if not, let a tangent be drawn parallel to the ordinate; then the diameter passing through the point of contact would bisect the ordinate, and thus the same line would be bisected in two different points, which is absurd.

Cor. 3. All the ordinates to the same diameter are parallel to each other.

Cor. 4. A straight line that bisects two parallel chords, and terminates in the curve, is a diameter.

Cor. 5. The ordinates to the axis are perpendicular to it, and no other diameter is perpendicular to its ordinates. This is evident from 3. Cor. Prop. 2. and 2. Cor. Prop.

Prop. X.

If a tangent at any point in a parabola meet a diameter, and from the point of contact an ordinate be drawn to that diameter, the segment of the diameter between the vertex and the tangent is equal to the segment between the vertex and the ordinate.

Fig 73. Let DH, a tangent to the curve at D, meet the diameter EP in H, and let DEd be an ordinate to that diameter: PH is equal to PE. For draw PK, a tangent at P, meeting the tangent DH in K; and draw iKI perpendicular to the diameter PE at i, meeting a diameter drawn through D at I: And because Hi is parallel to DI, and PK to DE, we have IK : iK :: DK : HK :: EP : HP (2. 6. E.), but IK = iK (2. Cor. 7.), therefore EP = HP.

Definition.

10. A straight line quadruple the distance between the vertex of a diameter and the directrix, is called the *Parameter*, also the *Latus Rectum* of that diameter.

Prop. XI.

If an ordinate to any diameter pass through the focus, the abscissa is equal to one fourth of the parameter of that diameter, and the ordinate is equal to the whole parameter.

Fig. 74. Let DEd, a straight line passing through the focus, be an ordinate to the diameter PE; the abscissa PE is equal to one fourth of the parameter, and the ordinate Dd is equal to the whole parameter of the diameter PE. Let DK, PI, be tangents at D and P; let DK meet the diameter in K; draw PF to the focus, and DL parallel to EP. The angles KPI, IPF, being equal (6.), and PI parallel to EF (2. Cor. 9.), the angles PEF, PFE, are also equal (29. 1. E.), and PE = PF = $\frac{1}{4}$ the parameter (Def. 1. and 10.) Again, the angle KDE is equal to LDK (6.), and therefore equal to DKE; consequently ED is equal to EK, or to twice EP (10.); therefore Dd is equal to 4 EP, or to 4 PF, that is, to the parameter of the diameter, (Def. 10.)

Prop. XII.

If any two diameters of a parabola be produced to meet a tangent to the curve, the segments of the diameters between their vertices and the tangent are to one another as the squares of the segments of the tangent intercepted between each diameter and the point of contact.

Let QH, RK, any two diameters, be produced to meet PI, a tangent to the curve at P, in the points G, I; then HG : KI :: PG^2 : PI^2. For let PN, a semiordinate to the diameter HQ, meet KR in O; and let PR, a semiordinate to the diameter KO, meet HN in Q; from H draw parallels to NO and QR, meeting KR in L and M; thus HL is a tangent to the curve, and HM a semiordinate to KR. Now KI = KR, and KL = KM, (10.) Therefore, by subtraction, LI = MR = HQ, but LO = HN = HG (10.); therefore, by addition, IO = GQ. The triangles PGN, PIO, are similar, as also PGQ, PIR; therefore GN : IO, or 2 GH : IO :: PG : PI, and GQ : IR, or IO : 2 IK :: PG : PI; hence, taking the rectangles of the corresponding terms, 2 GH . IO : 2 IO . IK :: PG^2 : PI^2; therefore GH : IK :: PG^2 : PI^2. Fig. 75.

Cor. The squares of semiordinates, and of ordinates to any diameter, are to one another as their corresponding abscissæ. Let HEh, KNk, be ordinates to the diameter PN; draw PG a tangent to the curve at the vertex of the diameter, and complete the parallelograms PEHG, PNKI; then PG, PI, are equal to EH, NK; and GH, IK, to PE, PN, respectively; therefore HE^2 : KN^2 :: PE : PN. Fig. 76.

Prop. XIII.

If an ordinate be drawn to any diameter of a parabola, the rectangle under the abscissa and the parameter of the diameter, is equal to the square of the semiordinate.

Let HBh be an ordinate to the diameter PB, the rectangle contained by PB and the parameter of the diameter is equal to the square of HB, the semiordinate. Let DEd be that ordinate to the diameter which passes through the focus. The semiordinates DE, Ed, are each half of the parameter; and the abscissa EP is one-fourth of the parameter (11.), therefore Dd : DE :: DE : PE, and Dd.PE = DE^2, but Dd.PE : Dd.PB :: (PE : PB ::) DE^2 : HB^2 (Cor. 12.), therefore Dd . PB = HB^2. Fig. 74.

Scholium.

It was on account of the equality of the square of the semiordinate to a rectangle contained by the parameter of the diameter and the abscissa, that Apollonius called the curve to which the property belongs a *Parabola.*

Prop. XIV.

A straight line drawn from the focus of a parabola, perpendicular to a tangent, is a mean proportional between the straight line drawn from the focus to the point of contact, and one-fourth of the parameter of the axis.

Let FB be a perpendicular from the focus upon the Fig. 77.

Parabola.

tangent PB, and FP a straight line drawn to the point of contact; let A be the vertex of the axis, and therefore FA equal to one-fourth of the parameter of the axis; FB is a mean proportional between FP and FA.

Produce FB and FA to meet the directrix in D and C, and join AB. The lines FC, FD, are bisected at A and B (Cor. Def. 1.—3. and 1. Cor. 6.); therefore, (2. 6. E.) AB is parallel to CD, or perpendicular to CF, and consequently a tangent to the curve at A (3. Cor. 2.); now BP is a tangent at P, therefore the angle AFB is equal to BFP (7.), and since the angles FAB, FBP, are right angles, the triangles FAB, FBP, are equiangular; hence FP : FB :: FB : FA.

Cor. 1. The common intersection of a tangent and a perpendicular from the focus to the tangent, is in a straight line touching the parabola at its vertex.

Cor. 2. If PH be drawn perpendicular to the tangent, meeting the axis in H, and HK be drawn perpendicular to PF, PK shall be equal to half the parameter of the axis. For the triangles HPK, PFB are manifestly equiangular; therefore HP : PK :: PF : FB :: FB : FA :: FD : FC. But if PD be joined, the line PD is evidently perpendicular to the directrix (6.); therefore the figure HPDF is a parallelogram, and HP = FD; therefore PK = FC = half the parameter of the axis.

Prop. XV. *Problem.*

A parabola being given by position, to find its directrix and focus.

Fig. 78. Let DPd be the given parabola; draw any two parallel chords Dd, Ee, and bisect them at H and K; join KH, meeting the parabola in P; the straight line PHK is a diameter (4 Cor. 9.), the point P is its vertex, and Dd, Ee are ordinates to it. In HP produced take PL, equal to one-fourth part of a third proportional to PH and HD, and draw LN perpendicular to PL, the line LN will evidently be the directrix (Def. 10. & Prop. 13.) Draw PM parallel to the ordinates to the diameter PK, then PM will be a tangent to the curve at P (2. Cor. 9.) Draw LM perpendicular to PM, and take MF = ML, and the point F will be the focus of the parabola, (1. Cor. 6.)

SECTION V.

Of the Curvature of the Conic Sections.

Definitions.

1. A circle is said to *touch* a conic section in any point, when the circle and conic section have a common tangent in that point.

2. If a circle touch a conic section in any point, so that no other circle touching it in the same point can pass between it and the conic section on either side of the point of contact, it is said to have the *same curvature* with the conic section in the point of contact, and it is called the *Circle of Curvature.*

Lemma.

Fig 79. Let PK be any chord in a circle, PX a tangent at one of its extremities, and KL a diameter passing through the other extremity; draw any chord Hh parallel to the tangent, meeting PK in E, and from its extremities draw HG, hg perpendicular to the diameter, meeting PK in M and m; the square of HE is equal to the rectangle contained by PE and KM, and the square of hE is equal to the rectangle contained by PE and Km.

Curvature.

From H and h draw the straight lines HP, hP, HK, hK, and let KN a perpendicular to the diameter, and therefore a tangent to the circle at K, meet PX in N. The triangle MHE is evidently similar to the triangle KNP, and KN = NP, therefore MH = HE; hence the angles HMK, HEP are equal. Now, PHE is equal to the alternate angle HPX, that is, to the angle HKM in the alternate segment of the circle (32. 3. E.), therefore the triangles PHE, HKM are similar, and PE : EH :: HM or EH : MK, therefore $HE^2 = PE.MK$. In the same way it may be demonstrated, that $mh = h$E, and that the triangles PhE, hKm are similar, and therefore PE : Eh :: hm or Eh : mK, and hence $hE^2 = PE.mK$.

Prop. I.

If a circle be described touching a conic section, and cutting off from the diameter that passes through the point of contact a segment greater than the parameter of that diameter, a part of the circumference on each side of the point of contact will be wholly without the conic section; but if it cuts off from the diameter a segment less than the parameter, a part of the circumference on each side of the point of contact will be wholly within the conic section.

Figs. 80, 81, 82, 83. Let Pp be the diameter of a conic section; let a circle HPh touch the section in P, the vertex of the diameter, and cut off a segment PK either greater or less than the parameter of the diameter: In the former case, a part HPh of the circumference of the circle on each side of P, the point of contact, will be wholly without the conic section, as in Fig. 80. and Fig. 81; and in the latter, a part HPh of the circumference on each side of P will be wholly within the section, as in Fig. 82. and Fig. 83. Through K, draw KL a diameter of the circle; let DEd, an ordinate to the diameter of the section, meet the circle in H and h, so that the points H, P, h may be on the same side of KL, the diameter of the circle, and draw HG, hg, PO perpendicular to KL, the two former lines meeting KP in M and m. From K, towards P, place KR in the diameter equal to its parameter: then, in the former case, the point R will fall between K and P, as in Fig. 80. and Fig. 81; and in the latter, it will fall in KP produced, as in Fig. 82. and Fig. 83.

Case 1. First, let the section be a parabola (Figs. 80. and 82.); then DE^2, also $dE^2 = PE.RK$ (Prop. 13. of Sect. IV.): Now $HE^2 = PE.KM$, and $hE^2 = PE.Km$ (Lemma): Therefore $DE^2 : HE^2 :: KR : KM$, and $dE^2 : hE^2 :: KR : Km$. Now, if the ordinate Dd be supposed to approach to the tangent at the vertex, the points H, h will approach to P, the lines HG, hg to the line PO, and the points M, m to the vertex P, where they will at last coincide; hence it is evident, that the ordinate DEd may be at such a distance from the tangent, that the points M, m, and the vertex P, may be all on the same side of the point R. In this position of the ordinate, if the segment cut off by the circle be greater than the parameter, as in Fig. 80, then KR will be less than either KM or Km, and therefore DE^2 less than HE^2, also dE^2 less than hE^2; so that the points H, h are both without the parabola. If the ordinate approach nearer to the tangent, as the points M, m will also approach nearer to P, the line KR will still be less than either KM, or Km, and therefore DE^2 less than HE^2, and dE^2 less than hE^2. Hence, every point

Curvature. in the arch HPh, which lies on each side of the point of contact, is wholly without the parabola.

If the segment cut off by the circle be less than the parameter (Fig. 82.), and therefore KR greater than either KM or Km, then, reasoning as before, it will appear that DE^2 is greater than HE^2, and dE^2 greater than hE^2, so that the points H, h are within the parabola; and as the same will hold for every other position of the ordinate nearer to the tangent, the arch HPh, which lies on each side of the point of contact, is wholly within the parabola.

Case 2. Next, let the section be an ellipse, or an hyperbola, (Fig. 81, 83.) * Take V a point in KR, so that $pP : pE :: KR : KV$, and therefore $Pp : KR :: pE : KV :: pE.EP : KV.EP$. But $Pp : KR :: pE.EP : DE^2$ or dE^2 (18. Sect. II. and 26. Sect. III.); therefore DE^2, also $dE^2 = KV.EP$. Now $HE^2 = KM.EP$, and $hE^2 = Km.EP$ (Lemma), therefore $DE^2 : HE^2 :: KV : KM$, and $dE^2 : hE^2 :: KV : Km$. Now, as Pp and RK are similarly divided at E and V, if E approach to P, the point V will approach to R, and as E may come nearer to P than any assignable line, so V may come nearer to R than any assignable line; but as then HG and hg will approach to PO, and M and m to P, it is evident that the ordinate Dd may have such a position, that the points M, m and the vertex P may be all on the same side of V, and the same thing may have place for every other position of the ordinate nearer to the tangent: therefore, in these circumstances, when KP, the segment cut off from the diameter, is greater than KR the parameter (Fig. 81.), KV will be less than either KM or Km, and consequently DE^2 less than HE^2, and dE^2 less than hE^2; thus the points H, h, as well as every other point in the arch HPh, which lies on both sides of the vertex, are without the ellipse or hyperbola. On the contrary, when KP is less than KR, the parameter (Fig. 83.), KV will be greater than either KM or Km, and therefore DE^2 greater than HE^2, also dE^2 greater than hE^2, and therefore the points H, h, as well as every other point in the arch HPh, are within the ellipse or hyperbola.

Cor. 1. If a circle touch a conic section, and cut off from the diameter that passes through the point of contact a segment equal to its parameter, it will have the same curvature with the conic section in the point of contact. For if a greater circle be described, it will cut off from the diameter a segment greater than its parameter, therefore a part of its circumference on each side of the point of contact will be wholly without the conic section; and as it will also be without the former circle, it will not pass between that circle and the conic section at the point of contact. If a less circle be described, it will cut off from the diameter a segment less than its parameter; therefore a part of its circumference on each side of the point of contact will fall within the conic section; and as it will be within the former circle, it will not pass between that circle and the conic section at the point of contact. Hence (Def. 2.) the circle which cuts off a segment equal to the parameter, is the circle of curvature.

Cor. 2. Only one circle can have the same curvature with a conic section in a given point.

Prop. II.

The circle of curvature at the vertex of the axis of a parabola, or at the vertex of the transverse axis of an ellipse or hyperbola, falls wholly within the conic section; but the circle of curvature at the vertex of the conjugate axis of an ellipse, falls wholly without the ellipse. Curvature.

Let Pp be the axis of a parabola (Fig. 84.), and $PHKh$ the circle of curvature at its vertex, which therefore cuts off from the axis a segment PK equal to the parameter of the axis; because the tangent at the vertex is common to the parabola and circle, the centre of the circle is in Pp. Let DEd, an ordinate to the axis, meet the circle in H and h; it may be shewn, as in the last proposition, that $DE^2 : HE^2 :: KP : KE$. But in every position of the ordinate, KP is greater than KE, therefore DE^2 is always greater than HE^2, and dE^2 greater than hE^2; therefore the circle is wholly within the parabola. Next let Pp be the transverse axis of an ellipse or hyperbola (Fig. 85, 86.), or the conjugate axis of an ellipse (Fig. 87.), and $PHKh$ the circle of curvature, then, as in the parabola, the centre of the circle will be in the axis. Draw Dd an ordinate to the axis, meeting the circle in H, h, and take a point V in PK, so that $pP : pE :: KP : KV$, then it will appear as in last Prop. that $DE^2 : HE^2 :: KV : KE$. Now, when Pp is the transverse axis of an ellipse (Fig. 85.), as Pp is greater than KP, and $Pp : PK :: PE : PV$; therefore PE is greater than PV, and hence KV is always greater than KE. Therefore DE^2 is greater than HE^2, also dE^2 greater than hE^2, so that the circle falls wholly within the ellipse. Again, when Pp is the transverse axis of an hyperbola (Fig. 86.) as pE is greater than pP, therefore KV is greater than KP, and consequently greater also than KE; hence DE^2 is greater than HE^2, and dE^2 is greater than hE^2, and the circle is wholly within the hyperbola. Lastly, when Pp is the conjugate axis of an ellipse (Fig. 87.), as Pp is less than KP, and $Pp : KP :: PE : PV$, therefore PE is less than PV; hence KV is less than KE, and consequently DE^2 is less than HE^2; also dE^2 less than hE^2, therefore the circle is wholly without the ellipse. Figs. 84, 85, 86, 87.

Prop. III.

The circle of curvature at the vertex of any diameter of a conic section which is not an axis, meets the conic section again in one point only, and between that point and the vertex of the diameter the circle falls wholly within the conic section on the one side, and wholly without it on the other.

Case I. Let the section be a parabola, of which Pp is a diameter (Fig. 88.), and PKL the circle of curvature at the vertex, cutting off from the diameter a segment PK equal to its parameter. Draw KL a diameter of the circle, and draw PO perpendicular to KL, this line will necessarily meet the circle again, let it meet the circle in I; draw IS parallel to the tangent at P, meeting the chord PK in S; then because IP is perpendicular to KL; $IS^2 = PS.PK$ (Lemma); hence (Prop. 13. Sect. IV.) I is a point in the parabola. Let DEd, an ordinate to the diameter Pp, meet the arch PKI any where in H; draw HG perpendicular to KL, meeting PK in M, then because KP is equal to the parameter, as in Prop. 1. Case 1. $DE^2 : HE^2 :: KP : KM :: KO : KG$. But wherever the point H be taken in the arch PKI, KO is greater than KG, therefore DE^2 is also greater than HE^2; thus the arch PHKI falls wholly within the parabola. Fig. 88.

* As the reasoning applies alike to the ellipse and the hyperbola, to avoid a number of figures, those for the hyperbola are omitted.

Let the ordinate DEd now meet the arch PLI any where as at h, draw hg perpendicular to KL, meeting KP in m, then it will appear as before that $dE^2 : hE^2 :: KP : Km :: KO : Kg$; but KO is less than Kg, and therefore dE^2 is less than hE^2, thus the arch $PhLI$ falls wholly without the parabola.

Fig. 89. CASE 2. Let the section be either an ellipse or hyperbola, of which Pp is a diameter, and PKL the circle of curvature at its vertex, cutting off PK equal to its parameter. Draw KL the diameter of the circle, and KQ perpendicular to KL, and let pQ, a tangent to the conic section in p, meet KQ in Q. Join PQ; this line will necessarily meet the circle again; let it meet the circle in I; and draw IS, IT parallel to Qp, QK meeting PK in S, T. Then because of the parallels, $pP : pS :: QP : QI :: KP : KT$, hence $pP : KP :: pS : KT :: pS.SP : KT.SP$; but $KT.SP = IS^2$ (Lemma) therefore $pP : KP :: pS.SP : SI^2$, hence I is a point in the ellipse or hyperbola. (Prop. 18. Sect. II. and 26. Sect. III.)

Let DEd an ordinate to the diameter Pp meet the arch PLKI any where in H, if the point K is between P and p, or the arch PHI, if K is in pP produced. Let Dd meet PI in Y, draw HG perpendicular to KL, meeting PK in M, and PI in Z, and draw YV parallel to HM, meeting KP in V. Because EY, pQ are parallel, also VY, KQ; $Pp : pE :: (QP : QY ::)\ KP : KV$; now KP being the parameter, we have, as in Case 2. Prop. 1. $DE^2 : HE^2 :: KV : KM :: QY : QZ$; but wherever the point H be taken in the arch PHI, QY is greater than QZ, therefore also DE^2 is greater than HE^2; thus the arch PHI falls wholly within the conic section.

Let the ordinate DEd now meet the other arch PhI any where in h; draw hg perpendicular to KL meeting KP in m, and IP in z, then it will in like manner appear that $dE^2 : hE^2 :: KV : Km :: QY : Qz$; and since in this case QY is less than Qz, therefore dE^2 is less than hE^2; hence the arch PhI is wholly without the conic section.

PROP. IV.

The chord of the circle of curvature which is drawn from the point of contact through the focus of a parabola, is equal to the chord which the circle cuts off from the diameter of the parabola; and half the radius of the circle is a third proportional to the perpendicular from the focus upon the tangent, and the distance of the point of contact from the focus.

Fig. 90. Let PK be the chord cut off from the diameter, and PFG the chord passing through F, the focus; draw PN the diameter of the circle, join GK, GN, and draw FL perpendicular to the tangent at P. Because the lines PFG, PK make equal aagles with the tangent at P (6. Sect. IV.) the angles PGK, PKG are equal (32. 3. E.); hence $PG = PK$.

Again, the triangles FLP, PGN being manifestly similar, $FL : FP :: PG$ or $4PF : PN$; hence $FL : FP :: FP : \frac{1}{4}PN$ or $\frac{1}{2}$ the radius.

COR. 1. Hence the radius is equal to $\dfrac{2\,FP^2}{FL}$

COR. 2. The radius is also equal to $\dfrac{2\,FL^3}{AF^2}$, where AF is the distance of the focus from the vertex of the parabola; for $FP = \dfrac{FL^2}{AF}$ (14. of Sect. IV.)

COR. 3. Hence also the radius is equal to $\dfrac{\frac{1}{2}L.FP^3}{FL^3}$, where L denotes the parameter of the axis, for $\dfrac{2\,FP^2}{FL}$ $= \dfrac{2\,AF.FP^3}{AF.FP.FL} = \dfrac{\frac{1}{2}L.FP^3}{FL^3}$.

PROP. V.

The radius of the circle of curvature at the vertex of any diameter of an ellipse or hyperbola is a third proportional to the perpendicular drawn from the centre upon the tangent and half the conjugate diameter; and the chord which is drawn from the point of contact through the focus, is a third proportional to the transverse axis and conjugate diameter.

Let PK be the chord cut off from the diameter, and PFG the chord passing through F, the focus; draw PN the diameter of the circle, and from the centre O draw OR perpendicular to PK, which will bisect PK in R; join GN, and draw the conjugate diameter QCq, meeting PG in M, and PN in S, then PS is equal to the perpendicular from the centre C upon the tangent. The triangles PSC, PRO are similar, therefore $PS : PC :: PR : PO$, but $PC : CQ :: CQ : PR$ (Def. of parameter),; therefore $PS : CQ :: CQ : PO$. Fig. 91.

Again, the triangles PSM, PGN are similar; therefore $PM : PS :: PN : PG$, but $PS : CQ :: (CQ : PO ::)\ Qq : PN$, therefore, $PM : CQ :: Qq : PG$, or since $PM = AC$ (Cor. 22. Sect. II. and Cor. 30. Sect. III.) $Aa : Qq :: Qq : PG$.

COR. 1. Hence the radius of curvature is equal to $\dfrac{CQ^2}{PS}$, and the chord passing through the focus is equal to $\dfrac{2\,CQ^2}{AC}$.

COR. 2. The radius of curvature is also equal to $\dfrac{CQ^3}{AC.BC}$, for $PS = \dfrac{AC.BC}{CQ}$. (Prop. 20. Sect. II. and Prop. 28. Sect. III.)

COR. 3. Draw FL from the focus perpendicular to the tangent, and let L denote the parameter of the transverse axis; the radius of curvature is also equal to $\dfrac{\frac{1}{2}L.FP^3}{FL^3}$. For the triangles PFL, MPS are manifestly similar, therefore $FL : FP :: (PS : PM \text{ or } AC ::)\ BC : CQ$; hence $CQ = \dfrac{FP}{FL} \times BC$, and $\dfrac{CQ^3}{AC.BC} = \dfrac{FP^3}{FL^3} \times \dfrac{BC^2}{AC} = \dfrac{FP^3}{FL^3} \times \frac{1}{2}L$.

This expression for the radius of curvature is the same for all the conic sections.

SECTION VI.

OF THE SECTIONS OF A CONE.

Definitions.

1. If ADB be a circle, and V a point out of its plane, both having a fixed position; and if a straight line aVA, indefinitely extended both ways, pass through V, and move in the circumference of the circle; when it has made a complete revolution, it will have gene- Fig. 92.

Sections of a Cone.

rated two superfices which meet at V, and include within them a solid called a *Cone.*

2. The point V is called the *Vertex of the Cone.*

3. The circle ADB is called its *Base.*

4. Any straight line drawn from the vertex of the cone to a point in the circumference of the base is called a *Side of the Cone.*

5. A straight line VC drawn from the vertex to the centre of the base, is called the *Axis of the Cone.*

Cor. Any section of a cone through the axis is a triangle.

Prop. I.

If a cone be cut by a plane parallel to its base, the section is a circle.

Fig. 92.

Let EFGM be the section, and the triangles VAB, VCD two other sections made by any two planes through the axis; let EG, OF be the common sections of these and the section EFG. Then, EO, FO, GO are parallel to AC, DC, BC respectively: therefore $AC : EO\ (:: CV : OV) :: DC : FO$; but $AC = DC$; therefore $EO = FO$; and in like manner it appears that $GO = FO$; therefore EFGM is a circle of which EG is the diameter.

Prop. II.

If a cone be cut by a plane which neither passes through the vertex, nor is parallel to the base, the section will be one or other of these figures, viz. a circle, an ellipse, an hyperbola, or a parabola.

Figs. 92, 93, 94.

Let PX be the common section of the base, and a plane passing through V, the vertex of the cone; and let FKM be a section of the cone parallel to the plane VPX. From C, the centre of the base, draw CN perpendicular to PX; meeting the circumference in A and B; and let a plane pass through V, A, B, and meet the plane XPV in the line NV, the surface of the cone in VA, and VB, and the plane of the section FKM in KL; then because the planes XVP, MKF are parallel, KL is parallel to VN.

Let EFGM be a section of the cone parallel to the base, meeting the plane VAB in EG, and the plane FKM in FM; and let L be the intersection of EG and FM; then EG will be parallel to BN; and FM is parallel to PX, and therefore will make the same angle with LK, wherever the lines FM, LK cut each other; and since BN is perpendicular to PX; EG is perpendicular to FM. Now the section EFGM is a circle, of which EG is the diameter (1.) therefore FM is bisected at L, and $FL^2 = EL.LG$.

Now there will be four cases, resulting from the different positions of the line VN in respect of the cone.

Fig. 92.

Cases 1. and 2. Let the line PNX fall without the base of the cone (Fig. 92.) Then KH will meet the opposite sides in K and H, below the vertex. Draw KR, HQ parallel to AB; then, the triangles KLG, KHQ are similar, as also HLE, HKR; therefore,

$$KL : LG :: KH : HQ,$$

$$\text{and } HL : LE :: KH : KR;$$

therefore taking the rectangles of the corresponding terms,

$$KL.LH : GL.LE \text{ or } LF^2 :: KH^2 : HQ.KR.$$

Now if the angles VKH, VAB are equal, then also $VKH = VRK$, and $HKQ = HRK$; and as the alternate angles RKH, HKQ are equal, the triangles RKH, HKQ are similar, so that $RK : KH :: KH : HQ$, and $HK^2 = HQ.KR$, therefore in this case $KL.LH = LF^2$, and consequently HFK is the circumference of a *circle,* of which KH is the diameter (35. 3. E.)

Areas of the Conic Sections.

Note. This particular section of a cone is called a *Subcontrary Section.*

If, however, the angles VKH, VAB be unequal, then HK^2 will not be equal to HQ.KR, but will have to it the same ratio wherever the point L is situated in the line HK; therefore, in this case KL.LH has a constant ratio to LF^2, and consequently the section HFK is an *ellipse,* of which HK is a diameter, and LF an ordinate (1. Cor. 16. Sect. II.)

Fig. 93.

Case 3. Next let the line PNX fall within the base of the cone, (Fig. 93.) then the plane FKM will meet the base in a line SID, and the line KL will meet AV, the side of the cone, at H a point above the vertex. Draw VT perpendicular to IH, and by similar triangles

$$HT : TV :: LH : LE,$$

$$\text{and } KT : TV :: KL : LG;$$

therefore, $HT.KT : TV^2 :: HL.LK : LE.LG \text{ or } LF^2$. Hence it appears that in this case, HL.LK has to LF^2 a constant ratio; therefore the section DFKMS is an hyperbola, of which KH is a transverse diameter, and FM an ordinate to that diameter. (2. Cor. 24. Sect. III.)

Fig. 94.

Case 4. Lastly, let the line PNX touch the circumference of the base in A, (Fig. 94.) In this case, DIS, the common section of the base and the plane FKM, is evidently parallel to FLM, and perpendicular to AB; therefore $DI^2 = AI.IB$, and $DI^2 : FL^2 :: AI.IB : EL.LG :: IB : LG$. But since EG is parallel to AB, and IK parallel to AV, we have $IB : LG :: KI : KL$; therefore $DI^2 : FL^2 :: KI : KL$; hence it follows that the section DFKMS is a parabola, of which KLI is a diameter, and DIS, FLM ordinates to that diameter. (Cor. to 12. Sect. IV.)

SECTION VII.

Of the Areas of the Conic Sections.

Prop. I.

Fig. 95.

If an ordinate AB, and abscissa PQ of a parabola be completed into a parallelogram ABCD; the area of the parabola included between the ordinate and the curve is two thirds of the parallelogram.

Draw the chords AP, PB; also draw the diameters Ff, Ii, to bisect the semiordinates AQ, QB in f and i, and draw the chords AF, FP, PI, IB. Again, draw the diameters Ee, Gg, Hh, Kk to bisect the distances between the points A, f, Q, i, B, and draw the chords AE, EF, FG, GP, PH, HI, IK, KB; and suppose this operation of drawing diameters to be repeated any number of times. By this process there will be formed successive series of triangles; the first consisting of one term, viz. APB; the second of two, viz. the triangles AFP, PIB; the third of four, viz. AEF, FGP, PHI, IKB, and so on.

Let Ff meet PD in M, and the chord PA in N; and because PA is manifestly an ordinate to the diameter Ff, (Def. 8. Sect. IV.) and PM a tangent, at the extremity of the ordinate; $FN = \frac{1}{2} MN$; but because $PM = Af$, it follows that $MN = Nf = \frac{1}{2} PQ$; therefore $FN = \frac{1}{4} PQ$. Now the triangles AFP, AQP, which have the same base AP, being to each other as their alti-

Areas of the Conic Sections.

tudes; they will also be to one another as FN to QP, which making equal angles with the common base, have the same ratio as the altitudes; therefore the triangle AFP is $\frac{1}{4}$ of the triangle APQ; and as in like manner it may be shewn that the triangle BIP is $\frac{1}{4}$ of the triangle BPQ; the triangles AFP, BIP are together $\frac{1}{4}$ of the triangle APB.

If a tangent be drawn at F, and produced to meet the two diameters E*e*, G*g*, it may be proved in the same manner, that the triangles AEF, PGF are the fourths of the triangles AFN, PFN, and therefore, that their sum is $\frac{1}{4}$ of the triangle AFP; and as it may also be shewn that the triangles PHI, BKI are together equal to $\frac{1}{4}$ of the triangle PIB, the four triangles AEF, FGP, PHI, IKB are together $\frac{1}{4}$ of the sum of the triangles AFP, PIB. Proceeding in this way, it appears that at every succeeding bisection, a new set of triangles is produced, which together are $\frac{1}{4}$ of the area of the preceding set.

Put S for the area of the parallelogram ADCB, then we have

Triangle $APB=\frac{1}{2}S$,

Polygon $AFPIB=(\frac{1}{2}+\frac{1}{8})S$,

Polygon $AEFGPHIKB=(\frac{1}{2}+\frac{1}{8}+\frac{1}{32})S$.

From the law according to which the terms in these numerical series are formed, it is evident that whatever be the number of sides of the polygon inscribed in the parabola, its area will be expressed by the geometrical series $(\frac{1}{2}+\frac{1}{8}+\frac{1}{32}+\frac{1}{64}+ \&c.)\ S$, the number of terms depending on the number of sides of the polygon. Suppose now the number of sides to be continually increased, then its area will manifestly approach continually to the area of the parabola, which is its limit, and will at last differ from it by less than any assignable space. Therefore the area of the parabola is exactly equal to the product of S, by the fraction which expresses the sum of the geometrical series continued indefinitely; now, observing that the first term is $\frac{1}{2}$, and common ratio $\frac{1}{4}$, the sum is readily found by a known formula to be $\frac{2}{3}$, (See Algebra, Art. 207.) therefore the area of the parabola is $\frac{2}{3}$ of the parallelogram ABCD.

Definition.

If the two axes of an hyperbola be equal, it is called an *Equilateral Hyperbola.*

Prop. II.

Fig. 96, 97. Let C be the centre of a circle, or of an equilateral hyperbola, and CA the semitransverse axis; let ACB, BCD be two equal sectors of the circle, or hyperbola, and let AHK, a tangent at the vertex A, meet the semidiameters CB, CD in H and K; then,

in the circle, $2\,CA : AK :: CA^2-AH^2 : CA.AH$,

and in the hyperbola, $2\,CA : AK :: CA^2+AH^2 : CA.AH$.

For draw DA, D*a* to the extremities of the axis; let the chord DA meet the semidiameter CB in O, and draw DE perpendicular to the axis; and because AO=OD, (Geometry, and Prop. 34. Part III.) and AC=C*a*, the line CO, *a* D are parallel (2. 6. E.) therefore the triangles CAH, *a*ED are similar; but because $ED^2=AE.Ea$ (Prop. 24. of Part III.) $AE:ED::ED:Ea$ (16. 6. E.) hence the triangles DEA, *a* ED are similar, (6. 6. E.) and each is similar to CAH; therefore

$Ea : ED :: AC : AH :: AC^2 : AC.AH$,

$EA : ED :: AH : AC :: AH^2 : AC.AH$,

Hence in the circle,

$Ea-EA$ or $2\,CE : ED :: AC^2-AH^2 : AC.AH$;

and in the hyperbola, (24. 5. E.)

$Ea+EA$ or $2\,CE : ED :: AC^2+AH^2 : AC.AH$.

But $2\,CE : ED :: 2\,CA : AK$

therefore $2\,CA : AK :: AC^2 \mp AH^2 : AC.AH$.

Prop. III.

If two ellipses, or two hyperbolas, have a common axis A *a*, and a semiordinate DD′E be drawn from the same point E in the axis, to each of the curves; the areas ADE, AD′E included between the common abscissa, the ordinates, and the two curves are to one another as the conjugate axes BC, B′C. Fig. 98, 99.

Let the common abscissa AE be divided into any number of equal parts A*p*, *p q*, *q* E; draw the semiordinates *p m′ m*, *q n′ n*, and the chords A *m*, *m n*, *n* D, also A *m′*, *m′ n′*, *n′* D′. And because $BC^2 : DE^2$ (:: $AC.Ca : AE.Ea$) :: $B'C^2 : D'E^2$ (1. Cor. 16. Part II, and 2. Cor. 24. Part III.), therefore $BC : DE :: B'C : D'E$, and $BC : B'C :: DE : D'E$; in like manner it appears that $BC : B'C :: nq : n'q :: mp : m'p$. Now, the triangle A *p m* is to the triangle A *p m′* as *m p* to *m′ p*, that is, as BC to B′C; and the trapezoid *p m n q* is evidently to the trapezoid *p m′ n′ q*, also the trapezoid *q n* DE to the trapezoid *q n′* D′E in the same ratio; therefore the polygon A *m n* DE is to the polygon A *m′ n′* D′E also as BC to B′C: and this will be true, whatever be the number of equal parts into which the common abscissa AE is divided. Suppose, now, that number to be indefinitely increased, then it is evident that the polygons will approach continually to the elliptic, or hyperbolic areas in which they are inscribed, so as at last to differ from them by less than any assignable space; therefore the elliptic, or hyperbolic spaces themselves, which are the limits of the polygons, are also to one another as BC to B′C.

Cor. 1. Hence it appears, that the area of an ellipse is to that of its circumscribing circle, as the conjugate axis to the transverse axis. For a circle may be considered as an ellipse having its axes equal.

Cor. 2. It also appears, that the area of any segment of an ellipse may be found from that of a corresponding segment of a circle: And the area of any hyperbolic segment from the corresponding segment of an equilateral hyperbola, having the same transverse axis.

Prop. IV. *Problem.*

To investigate a formula that shall express the area of a circle, or equilateral hyperbola.

Let ACD be a sector of a circle or hyperbola, and AC the radius of the circle, or semitransverse axis of the hyperbola. Let the sector be bisected by the semidiameter CB, and let each of the sectors ACB, BCD be bisected by the semidiameters CP, CQ; and proceed in this way, by repeated bisections, to divide the whole sector first into two equal parts, then into four, then into eight, and so on. Draw tangents to the curves at the alternate points A, B, D; and because, from the nature of the curves, the chords which join these points are ordinates to the semidiameters CP, CQ, which pass between them, the tangents will intersect each other at G, L, points in the semidiameters (1. Cor. Prop. 13. Sect. III.) Draw the chord AB joining any two contiguous points of contact, and let it meet CP in I; and because the triangles ACI, BCI are equal (38. 1. E.), as also the triangles AGI, BGI, by Fig. 100, 101.

Areas of the Conic Sections.

adding in Fig. 100, and subtracting in Fig. 101, the triangles CAG, CBG are equal: In the same way it appears, that the triangles DCL, BCL are equal. Again, because the semidiameter CB bisects the chord which joins P and Q, it will bisect GL, the tangent which is parallel to that chord; and therefore the triangles GCB, LCB are equal. Hence it follows, that the triangles ACG, GCB, BCL, LCD, are all equal; and this will be true, whatever be their number.

Let AK, a tangent at the vertex A, meet the semidiameters CP, CB, CD in G, H, K: Put the letter a to denote the semitransverse axis CA; and let the tangents AK, AH, AG, &c. which correspond to the whole sector, its half, its fourth, &c. be denoted by t, t', t'', &c. respectively: And because (by Prop. 2.) $2a:t::a^2\mp t'^2:at'$: (where the upper sign applies to the circle, and the lower to the hyperbola) we have $\frac{a^2}{t}=\frac{a^2}{2t'}\mp\frac{t'}{2}$; but as similarly $\frac{a^2}{t'}=\frac{a^2}{2t''}\mp\frac{t''}{2}$, we have, by substitution, $\frac{a^2}{t}=\frac{a^2}{4t''}\mp\left(\frac{t'}{2}+\frac{t''}{4}\right)$, and hence $\frac{a^3}{4at''}=\frac{a^2}{t}\pm\left(\frac{t'}{2}+\frac{t''}{4}\right)$. Now the expression $4at''$ or 4CA $\times$ AG (see Fig. 100. and 101.) is eight times the triangle ACG, that is double the polygon CAGBLD which circumscribes the circular, or is inscribed in the hyperbolic sector; therefore putting s' to denote the polygon, we have

$$\frac{a^3}{2s'}=\frac{a^2}{t}\pm\left(\frac{t'}{2}+\frac{t''}{4}\right).$$

If we carry on the process of bisecting the sector ACD indefinitely, so as to divide it next into 8, then into 16, then into 32 equal parts, and so on, and put t''' for the tangent corresponding to its 8th part, and t^{iv} for that corresponding to its 16th part, &c. we shall have in like manner,

$$\frac{a^3}{2s'}=\frac{a^2}{t}\pm\left(\frac{t'}{2}+\frac{t''}{4}+\frac{t'''}{8}+\frac{t^{\text{iv}}}{16}+, \text{ \&c.}\right)$$

Now the polygon CAGBLD manifestly approaches continually to the area of the sector, as the number of its sides is increased, and at last differs from it by less than any assignable quantity; therefore, putting now s for the area of the sector, if we substitute s in the above expression instead of s', and conceive the series of terms $\frac{t'}{2}$, $\frac{t''}{4}$, &c. to be continued *ad infinitum*, we have the quantity $\frac{a^3}{2s}$ expressed by an infinite series, from which we readily find

$$2s=\frac{a^3t}{a^2\pm t\left(\frac{t'}{2}+\frac{t''}{4}+\frac{t'''}{8}+, \text{ \&c.}\right)}$$

the formula to be investigated, and in which it must be observed, that the upper part of the sign $\pm$ applies to the circle, and the lower to the hyperbola.

As to the successive quantities t', t'', t''', &c. they may be determined from each other, and from t, by the series of formulas $2a^2t'=t\,(a^2\mp t'^2)$, $2a^2t''=t'\,(a^2\mp t''^2)$ &c. for it will be found by resolving a quadrate equation, that in the case of the circle,

$$t'=a\left\{\sqrt{\frac{a^2}{t^2}+1}-\frac{a}{t}\right\}:$$

but in the case of the hyperbola,

$$t'=a\left\{\frac{a}{t}-\sqrt{\frac{a^2}{t^2}-1}\right\};$$

and in the latter case the least root is taken, because t' ought to be less than t. The value of t'', t''', &c. are found each from that before it exactly as t' is found from t.

Scholium.

The formula for the determination of the tangents t', t'', t''', &c. each from that before it, in the case of the hyperbola, is entirely similar to that for the circle, differing from it only in the signs of the terms In the hyperbola, however, these tangents have a property which does not belong to them in the circle, by which their calculation may be facilitated: For since in the hyperbola

$$a:t::a^2+t'^2:2at', \text{ (by Prop. 2.)}$$

by mixing,

$$a+t:a-t::a^2+2at'+t'^2:a^2-2at'+t'^2;$$

that is, $a+t:a-t::(a+t')^2:(a-t')^2$;

and because, similarly,

$$a+t':a-t'::(a+t'')^2:(a-t'')^2,$$

and therefore

$$(a+t')^2:(a-t')^2::(a+t'')^4:(a-t'')^4;$$

therefore $a+t:a-t::(a+t'')^4:(a-t'')^4$;

and so on: Hence,

$$\frac{a+t'}{a-t'}=\left(\frac{a+t}{a-t}\right)^{\frac{1}{2}},$$

$$\frac{a+t''}{a-t''}=\left(\frac{a+t'}{a-t'}\right)^{\frac{1}{2}},$$

$$\frac{a+t'''}{a-t'''}=\left(\frac{a+t''}{a-t''}\right)^{\frac{1}{2}}, \text{ \&c.}$$

Let us now put $\frac{a+t}{a-t}=v$, then $\frac{a+t'}{a-t'}=v^{\frac{1}{2}}$, $\frac{a+t''}{a-t''}=v^{\frac{1}{4}}$, &c. therefore, resolving these equations in respect of t', t'', &c. we find $t'=a\frac{v^{\frac{1}{2}}-1}{v^{\frac{1}{2}}+1}$, $t''=a\frac{v^{\frac{1}{4}}-1}{v^{\frac{1}{4}}+1}$, $t'''=a\frac{v^{\frac{1}{8}}-1}{v^{\frac{1}{8}}+1}$, &c. This series of fractions, by which the tangents t', t'', &c. is expressed, being formed in a very simple manner from the square, the fourth, the eighth, &c. root of the fraction $v=\frac{a+t}{a-t}$, they may be easily computed, and thence the values of t', t'', &c. and sector s, found.

The tangents t', t'', &c. may also be readily found from the trigonometrical tables, for each is related to that which follows it, exactly as the sine of an angle to the tangent of half that angle. This may be proved as follows:

Put u and z to denote any two angles, then it appears, from the third and fourth formulas of Table D, Art. 12, Arithmetic of Sines, that

$$\frac{\text{Sin. }u+\text{Sin. }z}{\text{Sin. }u-\text{Sin. }z}=\frac{\text{Sin. }\frac{1}{2}(u+z)\text{ Cos. }\frac{1}{2}(u-z)}{\text{Cos. }\frac{1}{2}(u+z)\text{ Sin. }\frac{1}{2}(u-z)},$$

$$=\frac{\text{Tan. }\frac{1}{2}(u+z)}{\text{Tan. }\frac{1}{2}(u-z)}.$$

Now, by Art. 26,

$$\text{Tan. }\tfrac{1}{2}(u+z)=\frac{\text{Tan. }\frac{1}{2}u+\text{Tan. }\frac{1}{2}z}{1-\text{Tan. }\frac{1}{2}u\text{ Tan. }\frac{1}{2}z},$$

Areas of the Conic Sections.

$$\text{Tan.}\ \tfrac{1}{2}(u-z)=\frac{\text{Tan.}\ \frac{1}{2}u-\text{Tan.}\ \frac{1}{2}z}{1+\text{Tan.}\ \frac{1}{2}u\ \text{Tan.}\ \frac{1}{2}z},$$

therefore,

$$\frac{\text{Sin.}\ u+\text{Sin.}\ z}{\text{Sin.}\ u-\text{Sin.}\ z}=$$

$$\frac{(\text{Tan.}\ \frac{1}{2}u+\text{Tan.}\ \frac{1}{2}z)\ (1+\text{Tan.}\ \frac{1}{2}u\ \text{Tan.}\ \frac{1}{2}z)}{(\text{Tan.}\ \frac{1}{2}u-\text{Tan.}\ \frac{1}{2}z)\ (1-\text{Tan.}\ \frac{1}{2}u\ \text{Tan.}\ \frac{1}{2}z)}.$$

Suppose now that u is a right angle, so that Sin. $u=1$, and Tan. $\frac{1}{2}u=1$. In this case the formula becomes

$$\frac{1+\text{Sin.}\ z}{1-\text{Sin.}\ z}=\frac{(1+\text{Tan.}\ \frac{1}{2}z)^2}{(1-\text{Tan.}\ \frac{1}{2}z)^2}.$$

By comparing this formula with those which express the relation of t, t', t'', &c. to each other, viz.

$$\frac{1+\frac{t}{a}}{1-\frac{t}{a}}=\frac{\left(1+\frac{t'}{a}\right)^2}{\left(1-\frac{t'}{a}\right)^2},\qquad \frac{1+\frac{t'}{a}}{1-\frac{t'}{a}}=\frac{\left(1+\frac{t''}{a}\right)^2}{\left(1-\frac{t''}{a}\right)^2},\ \text{\&c.}$$

it will immediately appear, that the relation of $\frac{t}{a}$ to $\frac{t'}{a}$, also of $\frac{t'}{a}$ to $\frac{t''}{a}$, &c. is the very same as that of Sin. z to Tan. $\frac{1}{2}z$.

Hence it follows, that if we find from the trigonometrical tables the series of sines

Sin. z, Sin. z', Sin. z'', &c.

such that

$$\text{Sin.}\ z=\frac{t}{a},\ \text{Sin.}\ z'=\text{Tan.}\ \tfrac{1}{2}z,\ \text{Sin.}\ z''=\text{Tan.}\ \tfrac{1}{2}z',\ \text{\&c.}$$

and suppose s to express, as before, the hyperbole sector, then

$$2s=\frac{a^2 t}{a-t\ (\frac{1}{2}\ \text{Sin.}\ z'+\frac{1}{4}\ \text{Sin.}\ z''+\frac{1}{8}\ \text{Sin.}\ z'''+,\ \text{\&c.})}$$

The series in the denominator evidently approaches continually to a geometrical series, of which the common ratio is $\frac{1}{4}$; and because, in an infinite geometrical progression, whose common ratio is $\frac{1}{4}$, the sum of all the terms following any assigned term is exactly $\frac{1}{3}$ of that term, therefore any term of the series will be nearly triple of the sum of all that follow it, and this will be more nearly true as the term is farther from the beginning; the same also holds true of the series for the circle.

Prop. V. *Problem.*

Figs. 100, 101. To investigate a second formula that shall express the area of a circle or equilateral hyperbola.

Let the letters a, t, t', t'', &c. and s', s denote the same things as in last Proposition. Then because

$$\frac{a^2}{t}=\frac{a^2}{2t'}\mp\frac{t'}{2},$$

by taking the square of each side of the equation, we obtain

$$\frac{a^4}{t^2}=\frac{a^4}{4t'^2}+\frac{t'^2}{4}\mp\frac{a^2}{2};$$

and similarly we have

$$\frac{a^4}{t'^2}=\frac{a^4}{4t''^2}+\frac{t''^2}{4}\mp\frac{a^2}{2};$$

therefore, by substituting this value of $\frac{a^4}{t'^2}$ in the preceding equation, and taking the value of the term $\frac{a^4}{16t''^2}$, and also multiplying its numerator and denominator by a^2, we get

$$\frac{a^6}{16a^2t''^2}=\frac{a^4}{t^2}-\left(\frac{t'^2}{4}+\frac{t''^2}{4^2}\right)\pm a^2\left(\frac{1}{2}+\frac{1}{2.4}\right).$$

Now, $a t''$, being the numerical expression for the double of the triangle CAG, and $2at''$ that of the polygon s', and consequently, $16a^2t''^2$ that of $4s'^2$, we have only to substitute $4s'^2$ in the denominator of the first member of the equation, and the result will be an expression from which s' may be found; but as the terms of this expression will follow the same law, whatever be the number of quantities t', t'', &c. we have universally

$$\frac{a^6}{4s'^2}=\begin{cases}\frac{a^4}{t^2}-\left(\frac{t'^2}{4}+\frac{t''^2}{4^2}+\frac{t'''^2}{4^3}+,\ \text{\&c.}\right)\\ \pm a^2\left(\frac{1}{2}+\frac{1}{2.4}+\frac{1}{2.4^2}+,\ \text{\&c.}\right),\end{cases}$$

the two series being supposed continued to any extent whatever. Let us now suppose the series of quantities t, t', t'', t''', &c. to be continued indefinitely, then the numerical series $\frac{1}{2}+\frac{1}{2.4}+\frac{1}{2.4^2}+$, &c. being an infinite geometrical progression, whose common ratio is $\frac{1}{4}$, its sum will be $\frac{2}{3}$, and the limit of s' being s, we have

$$\frac{a^6}{4s^2}=\begin{cases}\frac{a^4}{t^2}\pm\frac{2}{3}a^2\\ -\left(\frac{t'^2}{4}+\frac{t''^2}{4^2}+\frac{t'''^2}{4^3}+,\ \text{\&c.}\right)\end{cases}$$

Let this equation be now resolved in respect of s^2, then extracting the square root, and putting

$$\text{T}=\frac{t'^2}{4}+\frac{t''^2}{4^2}+\frac{t'''^2}{4^3}+,\ \text{\&c.}$$

we have

$$2s=\frac{a^3t}{\sqrt{(a^4\pm\frac{2}{3}a^2t^2-t^2\text{T})}}$$

the formula to be investigated, and in which it must be observed, that the sign of the second term of the radical in the denominator is + for the circle and — for the hyperbola.

To determine the quantities t'^2, t''^2, &c. we have, from Prop. 2.

$$a:t::a^2\mp t'^2:2at',$$

the upper part of the sign $\mp$ applying to the case of the circle, and the lower to the hyperbola. Hence, in the former case, we have, by taking the squares

$$a^2:t^2::a^4-2a^2t'^2+t'^4:4a^2t'^2,$$

and, by conversion,

$$a^2:a^2+t^2::a^4-2a^2t'^2+t'^4:a^4+2a^2t'^2+t'^4;$$

therefore, taking the square roots,

$$a:\sqrt{(a^2+t^2)}::a^2-t'^2:a^2+t'^2,$$

and, by mixing,

$$\sqrt{(a^2+t^2)}+a:\sqrt{(a^2+t^2)}-a:2a^2:2t'^2::a^2:t'^2,$$

hence we find for the circle,

$$t'^2=\frac{a^2\left(\sqrt{(a^2+t^2)}-a\right)}{\sqrt{(a^2+t^2)}+a};$$

and, by proceeding in the very same manner it will appear, that in the hyperbola,

$$t'^2=\frac{a^2\left\{a-\sqrt{(a^2-t^2)}\right\}}{a+\sqrt{(a^2-t^2)}}$$

The quantities t''^2, t'''^2, &c. are derived each from that before it, exactly as t'^2 is from t^2.

Areas of the Conic Sections.

Scholium.

If, in the case of the circle, we denote the angle ACD by u, then $t = a \tan. u$, $\sqrt{(a^2+t^2)} = a \sec. u = \frac{a}{\cos. u}$, $\sqrt{(a^2+t^2)} - a = \frac{a(1-\cos. u)}{\cos. u}$, $\sqrt{(a^2+t^2)} + a = \frac{a(1+\cos. u)}{\cos. u}$; therefore,

$$t'^2 = a^2 \frac{1-\cos. u}{1+\cos. u},$$

$$t''^2 = a^2 \frac{1-\cos. \frac{1}{2}u}{1+\cos. \frac{1}{2}u},$$

$$t'''^2 = a^2 \frac{1-\cos. \frac{1}{4}u}{1+\cos. \frac{1}{4}u}, \text{ \&c.}$$

In this manner the quantities t'^2, t''^2, &c. may be readily formed from the cosines of the submultiples of the angle u; and these may be derived one from another by the formula $\cos. \frac{1}{2}u = \sqrt{\left(\frac{1+\cos. u}{2}\right)}$. A similar transformation may be made in the series T in the case of the hyperbola; also the quantities t'^2, t''^2, &c. may in this case be found from the trigonometrical tables, by considering, that if $\text{Sin.}\, z = \frac{t}{a}$, then $t'^2 = \text{Tan.}^2 \frac{1}{2} z$, &c. (Scholium to last Prop.) The series T, in this formula, converges more rapidly than that in the last, the terms approximating continually to those of a geometrical series, of which the common ratio is $\frac{1}{16}$; from which it follows, that the sum of all the terms following any term, is nearly $\frac{1}{15}$ of that term; and this is more nearly true, as the term is more advanced in the series.

By the same mode of deduction, other formulæ for the areas of a circle and hyperbola may be found, but for these we refer the reader to a paper in the fifth volume of the *Transactions of the Royal Society of Edinburgh*, by Mr Wallace, of the Royal Military College.

Sect. VIII.

On the Equations of the Conic Sections, and their Identity with Lines of the Second Order.

From the property of the conic sections, which we have employed in their definition, their *polar equation* may be immediately derived. Let us suppose, as in the definitions of Sections II. III. and IV. that the curves are traced by D, the extremity of a variable radius FD, which revolves about F, a fixed point, as a centre. This line has, in the application of the theory of these curves to astronomy, been called the *Radius Vector*. Put r for the line FD, z for the angle DFA, which it makes with the axis; d for FP, the distance of the focus from the directrix; and let the determining ratio be that of 1 to n, a given number. Draw DI perpendicular to the axis, and DE to the directrix; and because Rad. : Cos. z : : FD or r : FI, and $1 : n$: : FD or r : DE or IP, we have $\text{FI} = r \text{ Cos. } z$, $\text{IP} = n r$, and therefore $d = r \text{ Cos. } z + n r$, and

Figs. 3. 27. 61.

$$r = \frac{d}{n + \text{Cos. } z}; \;\ldots\ldots (1.)$$

This equation is common to all the sections. In the Ellipse and Hyperbola, put the eccentricity $\text{CF} = e$; the semitransverse axis $\text{CA} = a$; then because $1 : n : : e : a$, we have $n = \frac{a}{e}$, and

Equations of the Conic Sections.

$$r = \frac{e d}{a + e \text{ Cos. } z}; \;\ldots\ldots (2.)$$

This equation belongs to the Ellipse and Hyperbola.

Again, because when $z=0$, then $r = a - e$ in the ellipse, and $= e - a$ in the hyperbola; and as, in this case, $\text{Cos. } z = 1$, we have, in the former case, $e d = a^2 - e^2$; and in the latter $e d = e^2 - a^2$, therefore,

$$\left.\begin{array}{l} \text{In the Ellipse, } r = \dfrac{a^2 - e^2}{a + e \text{ Cos. } z}. \\ \text{In the Hyperbola, } r = \dfrac{e^2 - a^2}{a + e \text{ Cos. } z}. \end{array}\right\} \;\ldots\ldots (3.)$$

In the Parabola, put p for the parameter of the axis, then as in this case, $n=1$, we have

$$r = \frac{p}{2(1 + \text{Cos. } z)} \;\ldots\ldots (4.)$$

for the polar equation of the parabola.

Let us now suppose that the origin of the rectangular co-ordinates is at A, one of the vertices of the axis; put AI, the distance of the ordinate from the vertex, $= x$; ID the ordinate $= y$; and in the ellipse and hyperbola put BC the semiconjugate axis $= b$; then in the ellipse $a^2 : b^2 : : x(2a - x) : y^2$, (Sect. II. Prop. 16.); in the hyperbola $a^2 : b^2 : : x(2a + x) : y^2$, (Part III. Prop. 24.); therefore,

$$\left.\begin{array}{l} \text{In the Ellipse, } a^2 y^2 + b^2 x^2 - 2 a b^2 x = 0 \\ \text{In the Hyperbola, } a^2 y^2 - b^2 x^2 - 2 a b^2 x = 0 \\ \text{In the Parabola, } y^2 - p x = 0 \end{array}\right\} \;\ldots (5.)$$

In the ellipse and hyperbola, the centre may be taken as the origin of the co-ordinates, and then putting $\text{CI} = x'$, so that $x = a - x'$, we have

$$\left.\begin{array}{l} \text{In the Ellipse, } a^2 y^2 + b^2 x'^2 - a^2 b^2 = 0 \\ \text{In the Hyperbola, } a^2 y^2 - b^2 x'^2 + a^2 b^2 = 0 \end{array}\right\} \;\ldots (6.)$$

Since it appears that the rectangular co-ordinates of a conic *section* are in every case the variable quantities of an indeterminate equation of the second degree, it follows that every conic section is a line of the *second order*: The converse is also true, namely, that every line of the second order is a conic section, as we shall now demonstrate.

The equation to a line of the second order, in its most general form, is

$$\text{A} y^2 + \text{B} x y + \text{C} x^2 + \text{D} y + \text{E} x + \text{F} = 0,$$

where x and y denote co-ordinates to two axes, which are perpendicular to one another, (as explained in the theory of Curve Lines), and A, B, C, D, E, and F, are given quantities. By resolving this equation in respect of y, and putting $p = \text{B}^2 - 4\,\text{AC}$, $q = 2\,(\text{BD} - 2\,\text{AE})$, $r = \text{D}^2 - 4\,\text{AF}$, we find

$$y = -\frac{\text{B}x + \text{D}}{2\,\text{A}} \pm \frac{1}{2\text{A}} \sqrt{(p x^2 + q x + r)};$$

now that the equation may represent a real curve, the expression under the radical must be positive to all values of x within certain limits. If p be positive, we may suppose x to have such a value that $p x^2$ shall exceed the amount of the other terms, and every greater value of x will have the same property; so that in this case, the expression may always be positive. When p is negative, let the expression be put under this form,

$$\frac{1}{4p}\left\{(2 p x + q)^2 + 4 p r - q^2\right\}:$$

Then, in this case, to the values of x within certain limits, $(2 p x + q)^2 + 4 p r - q^2$ must also be negative, so that when multiplied by $\frac{1}{4p}$, the product may be positive, and consequently, changing the signs,

$$q^2 - 4 p r - (2 p x + q)^2,$$

must be positive; now the last term will always be negative, and it may evidently become as small as we please; therefore the whole expression may be rendered positive, provided that q^2-4pr or $4(BD-2AE)^2-4(B^2-4AC)(D^2-4AF)$ is a positive quantity. This expression when developed, and the common numerical multiplier rejected, gives us

$$A(AE^2+CD^2+FB^2-BDE-4AFC)$$

which, in the case of P or B^2-4AC being negative, must be a positive quantity, and this condition must be satisfied, otherwise the equation

$$Ay^2+Bxy+Cx^2+Dy+Ex+F=0$$

cannot represent a real curve.

Let the co-ordinates to any assumed point in the curve be a and b, so that

$$Ab^2+Bab+Ca^2+Db+Ea+F=0,$$

and let the origin of the co-ordinates be transferred to that point, by making

$$x=a+x',\ y=b+y';$$

x' and y' being new co-ordinates parallel to the former. Then we have

$$\left.\begin{array}{l} Ay'^2+Bx'y'+Cx'^2+(2Ab+Ba+D)y' \\ \quad +(2Ca+Bb+E)x' \end{array}\right\}=0$$

or, for greater simplicity, putting

$$2Ab+Ba+D=D',\ 2Ca+Bb+E=E',$$
$$Ay'^2+Bx'y'+Cx'^2+D'y'+E'x'=0.$$

Let us now change the direction of the co-ordinates x', y' about the new origin, at the same time keeping them at right angles to one another. This is done (see the article CURVES) by assuming

$$x'=x''\,\mathrm{Cos.}\,\alpha-y''\,\mathrm{Sin.}\,\alpha,\ y'=x''\,\mathrm{Sin.}\,\alpha+y''\,\mathrm{Cos.}\,\alpha,$$

x'' and y'' being new co-ordinates. By substituting these values of x' and y' we have

$$\left.\begin{array}{l} (A\,\mathrm{Cos.}^2\alpha-B\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha+C\,\mathrm{Sin.}^2\alpha)\,y''^2 \\ +(A\,\mathrm{Sin.}^2\alpha+B\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha+C\,\mathrm{Cos.}^2\alpha)\,x''^2 \\ +\left\{\begin{array}{l}2A\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha+B(\mathrm{Cos.}^2\alpha- \\ \quad \mathrm{Sin.}^2\alpha)-2C\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha\end{array}\right\}x''y'' \\ +(D'\mathrm{Cos.}\alpha-E'\mathrm{Sin.}\alpha)y''+(D'\mathrm{Sin.}\alpha+E'\mathrm{Cos.}\alpha)x'' \end{array}\right\}=0.$$

As the angle α is arbitrary, it may be taken such, that the term $x''y''$ may disappear; this will be the case if it satisfy the equation

$$\left.\begin{array}{l} 2A\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha+B(\mathrm{Cos.}^2\alpha-\mathrm{Sin.}^2\alpha) \\ \quad -2C\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha \end{array}\right\}=0.$$

But we have (ARITHMETIC OF SINES, Tables F. G.)
$\mathrm{Sin.}\,2\alpha=2\,\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha$, $\mathrm{Cos.}\,2\alpha=\mathrm{Cos.}^2\alpha-\mathrm{Sin.}^2\alpha$; therefore the equation which determines α may be put under this form

$$(A-C)\,\mathrm{Sin.}\,2\alpha+B\,\mathrm{Cos.}\,2\alpha=0,$$

which gives us

$$\mathrm{Tan.}\,2\alpha=-\frac{B}{A-C}.$$

The angle 2α will always be real, seeing that its tangent is real; thus the foregoing transformation and reduction are always possible. To introduce it into the equation, it must be observed that we have in general

$$\mathrm{Cos.}^2\alpha=\frac{1+\mathrm{Cos.}\,2\alpha}{2},\ \mathrm{Sin.}^2\alpha=\frac{1-\mathrm{Cos.}\,2\alpha}{2},$$

and by substituting these values and that of $\mathrm{Sin.}\,\alpha\,\mathrm{Cos.}\,\alpha$, we find the following expression equal to 0, viz.

$$\left\{A+C-B\,\mathrm{Sin.}\,2\alpha+(A-C)\,\mathrm{Cos.}\,2\alpha\right\}y''^2$$
$$+\left\{A+C+B\,\mathrm{Sin.}\,2\alpha-(A-C)\,\mathrm{Cos.}\,2\alpha\right\}x''^2$$
$$+2(D'\mathrm{Cos.}\,\alpha-E'\mathrm{Sin.}\,\alpha)\,y''+2(D'\mathrm{Sin.}\,\alpha+E'\mathrm{Cos.}\,\alpha)\,x''.$$

But from the value found for $\mathrm{Tan.}\,\alpha$, we get

$$\mathrm{Sin.}\,2\alpha=\frac{\mathrm{Tan.}\,2\alpha}{\surd(1+\mathrm{Tan.}^2 2\alpha)}=\frac{-B}{\surd\left\{B^2+(A-C)^2\right\}},$$

$$\mathrm{Cos.}\,2\alpha=\frac{1}{\surd(1+\mathrm{Tan.}^2 2\alpha)}=\frac{A-C}{\surd\left\{B^2+(A-C)^2\right\}};$$

if the co-efficients of y''^2 and x''^2 be represented by M and N, we shall find, by substituting these values of $\mathrm{Sin.}\,2\alpha$, and $\mathrm{Cos.}\,2\alpha$.

$$M=A+C+\surd\left\{B^2+(A-C)^2\right\},$$
$$N=A+C-\surd\left\{B^2+(A-C)^2\right\},$$

and the equation becomes

$$My''^2+Nx''^2+2(D'\,\mathrm{Cos.}\,\alpha-E'\,\mathrm{Sin.}\,\alpha)\,y''$$
$$+2(D'\,\mathrm{Sin.}\,\alpha+E'\,\mathrm{Cos.}\,\alpha)\,x''=0.$$

The co-efficients M and N are always real quantities, because $\mathrm{Tan.}\,2\alpha$ is a real quantity; but besides, M may be taken always positive, for that this may be the case, it is only necessary to dispose the terms of the equation so that A may be positive, which may always be done by changing the signs of the terms: And A being positive, if C is also positive, M will be entirely composed of positive quantities; but if C is negative, and equal to $-C$, the radical part which becomes then

$$\surd\left\{B^2+(A+C)^2\right\}$$

is greater than the rational part, which is then $A-C$: We shall therefore suppose M to be a positive quantity; as to N, it will be positive in some cases, and negative in others; and, in one case, it will be $=0$; for since $N=A+C-\surd\left\{B^2+(A-C)^2\right\}$; if $(A+C)^2 > B^2+(A-C)^2$, that is, if $4AC > B^2$, then N is positive. On the other hand, if $4AC < B^2$, then N is evidently negative; and if $4AC=B^2$, then in this case $N=0$; so that the equation may be expressed thus,

$$My''^2\pm Nx''^2+2(D'\,\mathrm{Cos.}\,\alpha-E'\,\mathrm{Sin.}\,\alpha)\,y''$$
$$+2(D'\,\mathrm{Sin.}\,\alpha+E'\,\mathrm{Cos.}\,\alpha)\,x''=0.$$

As this equation yet contains the quantities D', E', which are composed of the arbitrary co-ordinates a, b, we may make any other assumption that is consistent with the indetermination of x'' and y''. Let us therefore assume

$$2(D'\,\mathrm{Cos.}\,\alpha-E'\,\mathrm{Sin.}\,\alpha)=0;$$

by this, y'' vanishes from the equation; so that, if to abridge, we put

$$2(D'\,\mathrm{Sin.}\,\alpha+E'\,\mathrm{Cos.}\,\alpha)=P,$$

we have simply

$$My''^2\pm Nx''^2+Px''=0$$

which evidently belongs to an ellipse if N is positive, or to an hyperbola if N be negative; or, lastly, to a parabola if $N=0$, the origin of the co-ordinates being manifestly in each case the extremity of the axis.

The co-ordinates a, b, at first taken as arbitrary, may now be determined from the assumptions which have been made; for by multiplying the equation $2(D'\,\mathrm{Cos.}\,\alpha-E'\,\mathrm{Sin.}\,\alpha)=0$ by $\mathrm{Sin.}\,\alpha$, it becomes

Equations of the Conic Sections.

$$2 D' \text{Sin.}\, \alpha \,\text{Cos.}\, \alpha - 2 E' \text{Sin.}^2 \alpha = 0,$$

that is,

$$D' \text{Sin.}\, 2\alpha - E'(1 - \text{Cos.}\, 2\alpha) = 0;$$

this expression, by putting for Sin. 2α and Cos. 2α their values, gives us

$$BD' - E' \left\{ A - C - \sqrt{B^2 + (A-C)^2} \right\} = 0;$$

and this equation combined with the equation

$$A b^2 + B a b + C a^2 + D b + E a + F = 0$$

serves to determine the values of a and b. (ξ)

Coniston, Conjugation.

CONISTON. See LANCASHIRE.

CONJUGATION (from the Lat. *conjugare*, "to yoke together"), literally means *a yoking or pairing together;* whence, among the old anatomists, it was applied to nerves proceeding together from the brain, and serving the same operation, being used to denote what we commonly express by the term *pair of nerves.* This sense of the word, however, is now in a great measure obsolete; and the term conjugation is seldom employed, except in grammar.

Conjugation, in grammar, has sometimes been used to signify the orderly inflexion of verbs in all their different moods, tenses, and persons; and, undoubtedly, the term might, in just conformity to the original sense, be so applied; but, in fact, it is rarely employed in this extended meaning. It is now most generally restricted to denote "the mode of forming, in any particular language, the principal moods and tenses, or the radical parts of the verb, from which the various inflexions of the several moods and tenses originate, and by which their form is regulated."

The number of conjugations, or modes of forming the parts of the verbs, varies in different languages; in some there is but one, in others several. The origin of these different conjugations subsisting in the same language, probably was this: the inflexions of the verb were at first formed by uniting, or amalgamating, as it were, with the theme or radical part, certain pronouns, nouns, or particles. Experience (the great arbiter of language) soon indicated that certain of these themes coalesced more readily, or perhaps more smoothly, with the united words, either when certain vowels were interjected, or when the terminating syllables were lengthened, contracted, or otherwise modified. From convenience and custom, therefore, particular modifications in particular classes of verbs came to be generally adopted; and variations consequently taking place in the mode of forming the principal inflexions, these were distinguished by grammarians by the title of *conjugations.*

The number of conjugations, we have said, varies in different languages. This naturally arose from the different structure of the several languages. In Saxon, German, and many others, there is but one conjugation; in English, also, there is properly only one. Some English grammarians have indeed attempted to make *three,* founded on the peculiar formation of the past participle, as terminating in *ed* (or its contraction *t*), *ght,* and *en;* but as, by this scheme, the number of verbs of the first conjugation would, beyond all proportion, exceed those of both the others; and as, in fact, the peculiar formation of the participle in the second and third may easily be traced to the first, only admitting a small variation for the sake of euphony; the best English grammarians have concurred in reckoning only one conjugation, holding the other forms as only irregular deviations from the first. In Latin there are four conjugations, distinguished by the termination of the infinitive mood in *are, ēre, ĕre,* and *ire.* In some of the modern languages derived immediately from the

Conjugation ‖ Connecticut.

Latin, a similar variety only blending the long and short *ere,* occurs. Thus the Italian has three conjugations, in *are, ere, ire;* the Spanish has also three, in *ar, er,* and *ir;* the French varying a little from these, has four, in *er, ir, oir,* and *re.* In Greek, the older grammarians made no less than *thirteen* conjugations; six, called *Boryton's,* in ω, because the last syllable was marked with a grave accent; four, called *circumflex,* in ω, because admitting a contraction, and then marked with a circumflex accent; and four in μι. Dr Busby reduced these thirteen conjugations to four; but his distribution was very imperfect, classing similar forms under different conjugations, and different forms under the same. Messrs de Port Royal at last, with great propriety, reduced the whole to *two* verbs, terminating in the present of the indicative in ω and in μι, the former by far the most numerous, comprehending all the Barytone and circumflex conjugations of the old grammarians, the latter (probably merely the more ancient form of the verb occasionally retained in a few, though disused in the greater number) containing comparatively few verbs, and admitting four subdivisions according to the differences of the penult vowel. This arrangement possessing the advantages of superior simplicity and perspicuity, has long been universally adopted in Scotland, though it appears, by the Westminster and Eton grammars, that it is not yet generally received among the Greek scholars in England. The Hebrew grammarians, by improperly giving the names of *conjugations* to those forms of the verb which, in all other languages, would be termed *voices* or *moods;* hence they have formed no less than seven conjugations; the first five technically marked by the names, 1. *kal,* the *active* voice of the verb; 2. *niphal,* the *passive;* 3. *hiphil,* denoting the *operating power;* 4. its converse, or the *being operated upon;* 5. *reflected action,* nearly similar to the middle voice in Greek; and, in addition to these five, the Masoretic doctors, by the refinement of their points, have added other two: 6. *pihal,* or the performing a work *diligently;* and, 7. its passive *puhal;* the being *diligently performed.* These are, by the Hebrew grammarians, termed *conjugations,* using the term in a sense quite different from that in which it is employed in any other language. In Hebrew, there is, in fact, but one conjugation; the modification which it undergoes may constitute voices and moods, but ought not to be designated as different *conjugations.* (δ)

CONNAUGHT is the name of the western province of Ireland, which contains the counties of GALWAY, LEITRIM, MAYO, ROSCOMMON, and SLIGO. See these articles, for a Statistical Account of the Province.

CONNECTICUT, one of the United States of North America, comprehended within that part of the continent formerly called New England, and denominated by the ancient natives *Quennehticut,* is situated between

Connecticut. 41° and 42° 2′ north latitude, and between 71° 20′ and 73° 15′ west longitude. Its greatest breadth is about 72 miles, and its length 100 miles. It is bounded towards the north by Massachusets, on the east by Rhode Island; on the south by the sound which separates it from Long Island; and on the west by the state of New York.

Divisions. This state contains about 4674 square miles, equal to about 2,640,000 acres. It is divided into eight counties, viz. Fairfield, of which the chief towns are Fairfield and Danbury; New Haven, with a capital of the same name; Middlesex, the chief towns of which are Middlesex and Haddam; New London, of which the principal towns are New London and Norwich; and Litchfield, Hartford, Tolland, and Windham, each of which divisions respectively has a capital of the same name. Of these counties, the four former extend along the Sound from north to east; the others in the same direction, on the border of the state of Massachusets. They are divided into townships, which again are subdivided into parishes. The number of these townships is about 100, in each of which are contained two or more parishes, which are severally supplied with one or more places of public worship, and likewise school-houses at convenient distances. At New Haven there is a college.

Population. In 1756, the population of this state amounted to 130,611 persons; in 1774, to 197,856; in 1782, to 202,877 whites, and 6273 Indians and negroes; in 1790, to 237,496, exclusive of 2764 slaves; in 1800, to 251,002, of whom 121,113 were free white males, 123,528 free white females, 5300 free persons, except Indians, not taxed, and 951 slaves; and in 1810, to 261,727. The original stock, from which have sprung all the present occupiers of Connecticut, is said to have consisted of 3000 persons, chiefly from England, who settled here about the years 1635 and 1636.

Climate. Though exposed to the extremes of heat and cold, and to sudden changes of temperature, this country is very healthful. The north-west winds which prevail during the winter are keen, owing to the great body of snow which lies concealed from the influence of the sun in the immense north and north-west forests; but the serenity of the sky during the same season, makes amends in some degree for this severity of the weather. In the maritime towns, the weather is particularly variable, changing as the wind blows from the sea or land; in the inland country it is less so.

The territory of the state of Connecticut is generally broken land, made up of mountains, hills, and vallies. The soil is rich and fertile, though intermixed with portions that are comparatively thin and barren; and the whole is well watered. The principal productions are Indian corn, rye, wheat in many parts of the state, oats and barley, and of late some buck-wheat; flax in large quantities, some hemp, potatoes, pumpkins, turnips, pease, beans, &c. The principal object of the culture of the state consists, however, in its meadows, which enable the farmers to feed great numbers of neat cattle, horses, and other stock, with such advantage, that a given extent of good meadow land in Connecticut yields a return double of that derived from land laid under corn in the best districts of New York. Many farmers in the eastern part of the state have lately found their advantage in raising mules, which are carried to the West India islands.

The state of Connecticut is generally laid out in small farms, from 50 to 300 and 400 acres each, which are for the most part well cultivated. The country is intersected with numerous roads, in any of which, even in the most unsettled parts of the state, a traveller can seldom proceed more than two or three miles without finding a house or cottage, and a farm under such improvements as to afford the necessaries for the support of a family.

Rivers. The principal rivers of Connecticut are one of the same name, the Housatonick, and the Thames.

The Connecticut, which is the principal river in the eastern part of the United States, rises in the high lands which separate the states of Vermont and New Hampshire from Lower Canada. It has been surveyed about 25 miles beyond the 45° of latitude, to the head spring of its northern branch; from which, to its mouth, it flows upwards of 300 miles, through a well inhabited country. It fertilizes the lands through which it runs, but its navigation is much interrupted by falls. Some of these occur at Enfield in this state, at which place, to render the river navigable for boats, a company has been incorporated, and a sum of money raised by lottery. The principal stream which it receives within the Connecticut state, is the Farmington, which falls into it from the west at Windsor. At Hartford it meets the tide, whence it passes on in a winding course, till it falls into Long Island Sound, between Saybrook and Lyme. At its mouth there is a bar of sand, on which, however, at full tide, there is a depth of water of 10 feet. Above Middleton there are some shoals which, even at high tide, when the increase in the depth of the water may be about eight inches, are not more than six feet deep. About three miles from this city, the river is contracted by two mountains to the space of about 40 rods; but even so much farther up the stream as at 130 miles from its mouth, the breadth is from 80 to 100 rods, and commonly the banks are low, spreading into fine extensive meadows, which in the spring floods are covered with water. Notwithstanding the bar just mentioned, this river is navigable as far as Hartford, 50 miles distant from its mouth, for vessels of some burden, and the produce of the country for 200 miles above it is brought thither in flat-bottomed boats, which were so light as to be portable in carts. An important improvement was effected in 1795, by the completion of the locks and canals round the falls at South Hadley. Sturgeon, salmon, and shad are caught in abundance in this river, likewise a variety of small fish, such as pike, carp, and perch. In 1789, there were employed from or upon it three brigs of 180 tons each in the European trade, and about 60 sail from 60 to 150 tons in the West India trade, besides a few fishermen, and 40 or 50 coasting vessels; and a considerable increase has since taken place in these numbers.

Of the Housatonick river, one branch rises in Lanesborough, the other in Windsor, both in Massachussets. After passing a number of towns, it empties itself into the Sound, between Stratford and Milford, being navigable for 12 miles as far as to Derby, but with an obstruction in the way of large vessels, arising from a bar of shells at its mouth. Between Salisbury and Canaan there is a cataract in its course, where its whole water, which is here 150 yards wide, falls about 60 feet perpendicularly in a perfectly white sheet.

The Thames falls into Long Island Sound at New London, being navigable for 14 miles from its mouth to Norwich landing. At this point it divides into two branches, Norwich, or Little River, on the west, and on the east Shetucket. About a mile from the mouth of the former of these, there is a remarkable and very romantic cataract. The whole of the river having first pitched, in an entire sheet, over a rock 10 or 12 feet in perpendicular height, which extends quite across, is

Connecticut. Rivers.

channel, and then swiftly tumbling, foaming with the most violent agitation, for the space of about 15 or 20 rods, over the narrow, crooked, and gradually descending rocky bed, that next receives it, falls at length into a broad bason. The smoothness of the water above the descent, the regularity and beauty of the perpendicular fall, the tremendous roughness of the other, the curious excavations produced in the rock by the long continued impulses of the water, with the craggy towering cliffs which, on each side of the river, on one of them particularly, impend, the whole presenting to the view a scene highly striking and majestic. On this river, which in each of its branches is fed by numberless brooks from every part of the adjacent country, there occur some of the finest mill-seats in New England, or perhaps in the world.

Besides the Naugatuck and the Farmington rivers, which severally empty themselves into the Housatonick and the Connecticut, there are also the East or North-Haven river, the Mill river, and West river, with a number of other small rivers west of the Housatonick, none of which are of any great consideration. Of those last mentioned, the Byram may be noticed, as forming a part of the boundary between this state and New York.

Harbours. The whole of the sea-coast of Connecticut is indented with harbours, many of which are safe and commodious. The two principal ones are at New London and New Haven. The former opens to the south; the distance from the light-house, which stands at it mouth, to the town, being about three miles, its breadth three-fourths of a mile, and in some places more. The depth of water in the harbour is from five to six fathoms, with a clear bottom, tough ooze, and for a mile above the town, secure and commodious stations for large ships. The harbour of New Haven is greatly inferior to this. It is a bay which sets up northerly from the Sound about four miles, with good anchoring ground; but no where any considerable depth of water. Its entrance is about half a mile wide.

Mines. Mines of different kinds have been found in this state, but in general they have not been wrought to any considerable extent. On the banks of the Connecticut, two miles from Middleton, there is one of lead, which while wrought during the war, was found productive, but attended with great expence. Copper mines have been discovered and opened in several parts of the state, but having proved unprofitable, have been much neglected. The same thing may be said of the zinc mines. Iron mines are numerous and productive. Steel ore has been found in the mountains between Woodbury and New Milford. There occur here also talcs of various kinds; white, brown, and chocolate-coloured crystals, with several other fossils and metals. At Stafford there is a medicinal spring, which is said to be a sovereign remedy for scorbutic, cutaneous, and other disorders. There has also been observed a spring at Guildford, of the water of which it is mentioned as a peculiarity, that when taken from the fountain it will evaporate, even though put into a bottle, and tightly corked.

Manufactures. The linens and woollens of Connecticut are for the most part manufactured by individuals; the farmers of this state, with their families, being usually clothed in plain, decent, homespun cloth, which, though of a coarser kind, is commonly of a stronger texture, and much more durable than those imported from France and Great Britain. There are, however, other cloths also produced here, which are fine and handsome. In Hartford, a woollen manufacture has been established, and is protected by the legislature, which promises to be successful. At New Haven, there are flourishing linen and button manufactories. Large orchards of mulberry trees are raised in this state; and silk worms have been reared so successfully, as to promise not only a supply of silk to the inhabitants, but even to afford a surplus for exportation. In East Hartford, there are glass-works, a snuff and powder mill, iron-works, and a slitting-mill. Iron-works are established also at Salisbury, Norwich, and other parts of the state, while a sufficient supply for the whole of it of hollow ware and other ironmongery may be obtained from the furnace which has been erected at Stafford. Paper is manufactured at Norwich, Hartford, New Haven, and in Litchfield county. Nails of every size are made in almost every town and village in Connecticut, of which considerable quantities can be exported to the neighbouring states, and at a better rate than they can be had from Europe. Hats of the best kinds, candles, leather, shoes and boots, are prepared in this state, besides wooden dishes, and other wooden wares, which are made in vast quantities in Suffield and other places, and sold in almost every part of the eastern states. From the seed of the sun-flower, there is here expressed an oil, which is as mild as sweet-oil, and is equally agreeable with sallads and as a medicine: it may also be used in paints, varnishes, and ointments. Oil mills, of a new and very ingenious construction have been erected in several parts, for the expression of this oil; while, from the quantity of it that may be drawn from any given extent of ground, and the price which it yields in the market, the business of its preparation is found to be very profitable for those engaged in it. At Stratford there is farther established a duck manufactory.

Trade. The trade of Connecticut is chiefly with the West India islands, the exports to which consist of horses, mules, oxen, oak-staves, hoops, pine-boards, oak planks, beans, Indian corn, fish, beef, pork, &c. This traffic is carried on in vessels from 60 to 140 tons burden. A great number of coasting vessels is also employed in carrying the produce of this to the other states. The articles supplied to those different states are different. To Rhode Island, Massachussets, and New Hampshire, are furnished pork, wheat, corn, and rye; to North and South Carolina, and Georgia, butter, cheese, salted beef, cider, apples, potatoes, and hay, in return for which are obtained chiefly rice, indigo, and money. A good deal of the whole trade with these states is conducted through the medium of the markets of New York; the chief of the articles thus conveyed being pot and pearl ashes, flax-seed, beef, pork, cheese, and butter.

A considerable proportion of the produce of the eastern parts of the state, is disposed of at Boston, Providence, and Norwich. The value of the whole exported produce and commodities from the state of Connecticut before the year 1774, was then estimated at about L.200,000 annually. In the year ending September 30. 1791, the amount of foreign exports was 710,340 dollars, independently of articles to a great value carried to different parts of the United States. In 1792, it was 749,925 dollars; in 1793, 770,239 dollars; in 1794, 806,746 dollars; and in 1804, 1,516,110, of which 1,486,882 are to be included under the head of domestic, and 29,228 of foreign trade. This state employs in the two branches of its business, the foreign and the coasting, upwards of 32,897 tons of shipping.

Vessels

In 1774, the number of its vessels had been 180; their tonnage 10,317; seafaring men 1162, besides upwards of 20 sail of coasting vessels, which employed about 90 seamen. Various causes concurred rather to diminish for a time than to increase these amounts; the more favourable state of which, at periods more recent, is at once an indication and a consequence of the generally increasing prosperity of the state.

Towns.

There is in Connecticut a great number of very pleasant towns, both maritime and inland. It contains five cities, incorporated with extensive jurisdiction in civil causes. The capitals of the state are Hartford and Newhaven. At the former of which the General Assembly is holden annually in May, at the latter in October. Hartford, situated, as has been said at the head of navigation, on the west side of Connecticut river, has a very fine back country, enters largely into the manufacturing business, and occupying an advantageous position for trade, is a rich flourishing commercial town. Newhaven, lying round the head of the bay of the same name, covers part of a large plain, which is circumscribed on three sides by high hills or mountains, and on the east and west is bounded by two small rivers. The situation is in a high degree at once pleasant and healthful, and the state of the town prosperous. It carries on a considerable trade with New York and the West India islands. New London stands on the west side of the river Thames, near its entrance into the sound, in lat. 41° 25′, both in respect of its situation generally, and of the goodness of its harbour, enjoying considerable facilities for the prosecution of trade. Norwich, which is situated at the upper part of the same river, avails itself of the natural advantages which it possesses, as being placed at the head of navigation with a rich and extensive back country, and with the command of many convenient sites for mills and water machines of all kinds, being, as in such circumstances was reasonably to have been expected, a considerable manufacturing and trading town. The executive courts of law are held alternately here and at New London. Middleton, which is pleasantly situated on the western bank of Connecticut river, 15 miles south of Hartford, carries on, like that town, a large and increasing trade. Of other towns more or less considerable in this state, there are, on the banks of the river just mentioned, Saybrook, Haddam, Weathersfield, Windsor, Suffield, Enfield, East Windsor, East Hartford, Glastonbury, East Haddam, and Syme. Farmington, Litchfield, Milford, Stratford, Fairfield, and Guildford, are also all rather respectable and very pleasant towns.

Religion.

There are very few religious sects in this state, the bulk of the people being Congregationalists. There are, however, some Episcopalians and Baptists, and at Newhaven there is a society of Sandemanians. The Episcopalian churches are respectable, and are under the superintendence of a bishop. The education of all ranks of people is attended to here with as much assiduity, perhaps, as in any part of the world. Almost every town in the state is divided into districts, each of which has its public school, that is kept in it a greater or less part of every year. Somewhat more than a third of the monies arising from a tax on the polls and rateable estate of the inhabitants, is appropriated to the support of education in the several towns. In every county town throughout the state, it is directed by the law that there shall be a grammar school. Academies have also been established at several places within its bounds, some of which are in a very flourishing condition. Yale college, now in Newhaven, is an eminent seminary of learning; it was founded in the year 1700. The first charter of incorporation in its favour was granted to eleven ministers, under the denomination of trustees, in 1701. The powers of the trustees were enlarged by the additional charter 1723. And by that of 1745 they were incorporated by the name of the President and Fellows of Yale College, Newhaven. The corporation are empowered to hold estates, continue their succession, make academic laws, elect and constitute all officers of instruction and government usual in universities, and confer all learned degrees. The ordinary executive government is in the hands of the president and tutors. The course of education in this university comprehends the three learned languages, together with so much of the sciences as can be communicated in four years. Great attention is paid also to oratory and the belles lettres. The public library belonging to the university consists of about 2500 volumes, and the philosophical apparatus contains at least the principal machines necessary for exhibiting most of the experiments usually introduced in courses of experimental philosophy and of astronomy. In the college museum, to which additions are constantly making, there are several natural curiosities. Proportionable to the attention given towards furnishing the means, is the thirst for learning which prevails among all ranks of people in this community. More of the young men in Connecticut, relatively to their numbers, receive a public education than in any of the other states. Some have thought, and perhaps not without reason, that the fondness for academic and collegiate education, is here too great, tending to draw off more than enough from the primarily useful occupations. It may be supposed also to be a consequence of this sedulous direction of the youthful mind to learning, that there is found in the national character so much of a certain gravity and seriousness of deportment, accompanied with a degree of shyness and reserve, that cannot fail to appear to strangers in rather a forbidding and disagreeable light. Be that as it may, it is yet to be understood that it is only on the occasion of a first introduction that this temper materially shews itself. On better acquaintance, the people of this state are found to be abundantly familiar and inquisitive, and their hospitality is highly exemplary and laudable. In respect to external appearance and manners, the men of the state of Connecticut are commonly tall, stout, and robust; the women are fair, genteel, and handsome; they are moreover strictly virtuous, and often well informed. The prevailing amusements here are dancing, fishing, hunting, skaiting, and riding in sleighs * on the ice. In winter, the sleigh is also much in use for travelling. At other seasons, the common mode of travelling, both for men and women, is on horseback. The luxury of wheel carriages is, at the same time, by no means altogether unknown.

Education, &c.

Constitution.

The constitution of Connecticut is founded on its charter, which was granted by Charles II. in 1662, and on a law of the state. By these the supreme legislative authority is vested in a governor, deputy-governor,

* The sleigh is a vehicle which hangs on four posts, standing on two steel sliders or large skates. It is drawn by two horses, and can carry six persons.

Connecticut. Constitution.

twelve assistants or counsellors, and the representatives of the people, styled the General Assembly. The governor, deputy-governor, and assistants, are annually chosen by the freemen in the month of May. The representatives, of whom the number is not to exceed two from each town, and who generally amount from 160 to 180, are chosen by the same body twice in the year, to attend the two annual sessions held on the second Tuesdays of May and of October. The general assembly is divided into two branches, distinguished as the upper and lower houses: the former is composed of the governor, deputy-governor, and assistants: the latter of the representatives of the people. No law can pass without the concurrence of both these houses. The assembly, in its collective capacity, has power to erect judicatories for trying causes civil and criminal, as well as to establish laws for settling the forms and ceremonies of government. The judges of the superior court there appointed, hold their offices during the pleasure of the same assembly. The judges of the county courts and justices are appointed annually. Sheriffs are nominated by the governor and council without limitation of time. The governor is captain-general of the militia; the deputy-governor lieutenant-general: all other military offices are appointed by the assembly, and commissioned by the governor. The freemen in general are eligible to any office of government: their qualifications are maturity in years, quiet and peaceable behaviour, a civil conversation, and freehold estate to the value of 40s. per annum, or £40 personal estate in the list, certified by the select men of the town: it is necessary also that they should take the oath of fidelity to the state.

The people of Connecticut have had the good sense to avoid a change of constitution, notwithstanding the declaration of independence. The revolution which so essentially affected the government of most of the colonies, produced here no very perceptible effect. While under the jurisdiction of Great Britain, this state elected its own governors and all subordinate civil officers, and made its own laws in the same manner, and with as little controul as it still continues to do. Connecticut has ever been a republic, and exhibits perhaps one of the best examples of a perfect and happy government of that kind. While other states accordingly more monarchical in their government and manners, have been laid under the necessity of introducing, in both respects, important and difficult alterations, Connecticut has proceeded uninterruptedly in her old track, and thus has escaped the convulsions by which they have been so much torn and agitated.

Courts, &c.

The common law of England, so far as it is applicable here, is considered also as the common law of this state. The reports of adjudication in the courts of King's Bench, Common Pleas, and Chancery, are accordingly read in its courts as authorities; which are, however, not deemed by the judges to be binding, further than as they are founded on solid reasons directly affecting their state, or sanctioned by concurrent adjudications of their own courts. Pardons and reprieves can be granted only by the General Assembly, likewise commissions of bankruptcy, or protection to the persons and estates of unfortunate debtors. The supreme court of errors, consisting of the deputy-governor and twelve assistants, determine writs of error brought on judgments of the superior court. This latter, which is a circuit court, and has two stated annual sessions in each county, consists of five judges, who have authority in all criminal cases extending to life, limb, or banishment, and other high crimes and misdemeanors, also to grant divorces, and to hear and determine all civil actions brought by appeal from the county courts or the court of probate, and to correct the errors of all inferior courts. Of the courts of probate, the peculiar province is the probate of wills, granting administration on intestate estates, ordinary distribution of them, and appointing guardians for minors. The county courts, which are held respectively by one judge and four justices, have jurisdiction in all criminal cases arising within their several counties, where the punishment does not extend to life, limb, or banishment. They have original jurisdiction also in all civil actions which exceed the cognizance of a justice. Of the justices, a number of whom is appointed annually in each town by the General Assembly, the authority extends to the hearing and determining of civil actions, where the demand does not exceed four pounds, likewise to small offences, punishable within prescribed and very narrow limits, by fine, whipping, or sitting in the stocks. Writs are issued through the state, by assistants and judges, as by the justices through their respective counties. In these must be contained the substance of the complaints or declarations which give occasion for them; and if neither of the parties show good reason for delay, the causes are heard and determined the same term to which the writs are returnable. The plaintiff has always his election to attach or to summon the defendant. There is here no attorney-general, but there is an attorney to the state for each county. Few of what are called the fictions of law are here known or put in practice. The county courts admit and qualify those who are to act as practitioners before them, who being so admitted, have the privilege, without farther qualification, of practising in any court of the state.

In this state the feudal system of descents has never been adopted. The whole real property of intestates is divided equally among the children, males and females, the eldest son, however, having a double portion; and it is provided, that all estates given in tail, must be given to some persons then in being, or to their immediate issue, or shall become fee-simple estates to the issue of the first donee in tail. The widow of an intestate is entitled to a third part of the personal estate for ever, and during her life to a third part of the houses and lands which belonged to him at the time of his death. With a view to the defraying of the public expences, all freeholders in the state are required by law to give in, at a particular season, lists of their polls and rateable property to persons appointed in the several towns to receive them. These being valued, are arranged in proper order, and forwarded to the general assembly. On their amount, taxes are levied at rates per pound proportioned to the extent of the sums proposed to be raised. The ordinary annual expences of government before the war, amounted to near £4000 sterling, exclusive of that which was appropriated to the support of schools. This amount has since been increased.

Territory.

The territory of Connecticut, at the time that the English first arrived thither, was possessed by the Pequot, the Mohegan, Podunk, and many other smaller tribes of Indians. The Pequots were numerous and warlike. Their country extended along the sea coast from Paukatuck to Connecticut river; and about the year 1630, their conquests, besides other territory, reached over a considerable portion of what is now comprehended under this state: the seat of the sovereign of the whole nation was Pequot. The Mohegans were numerous, and their territory extensive, containing most

Connecticut. of New London county, almost the whole county of Windham, and a part of the counties of Tolland and Hartford. The Podunks inhabited East Hartford, and the adjacent country. In 1774, there remained of the descendants of these ancient nations not more than 1363 persons, who lived chiefly at Mohegan, between Norwich and New London. The Indian population in this state has, since that period, still continued to be so rapidly on the decrease, that it has been concluded their whole number does not now exceed 400.

History, &c. The first grant of Connecticut was made by the Plymouth council to the Earl of Warwick in 1630, who, in the following year, assigned it to Lord Say and others. Some Indian traders settled at Windsor in 1633. The same year in which, a little before the arrival of the English, a few Dutch traders had settled at Hartford, and the remains of whose settlement are still visible on the bank of Connecticut river. In 1634, the English built the fort of Saybrook, and purchased from the Pequot Indians the lands on the banks of that river. The right of conquest gradually extended the possessions of the English, who established themselves at New Haven in 1638. This new colony at first formed a distinct body politic, which was not united to that of Connecticut till the year 1665. These rising colonies during that interval, present the disgusting picture of religious persecutions among men, whom every thing should have conspired to unite. The Quakers, who were the principal objects of it there as in Europe, owed to it their increase. The colony at length gained considerable enlargement. The Connecticut adventurers had, in 1644, purchased of Mr Fenwick, agent for Lord Say, and the others concerned, their right to the possession of it for £1600. Tracts of land continued to be procured from the Indians, and new towns were settled from Stamford to Stonington, as well as far back into the country. In 1661, all the lands connected with it, which had not previously been purchased by particular towns, were bought of the natives, and a public surrender made of them to the colony in the presence of the General Assembly. It was in the year subsequent to this, that it obtained from Charles II. the charter of its liberty and union. Ten years thereafter, its laws were formed into a uniform code, and on every individual was imposed the duty of making himself acquainted with them. A copy of this code, which was reprinted in a small volume in 1750, and of which Dr Douglas says that there can be none more natural, more equitable, more simple, or more concise, was to be purchased by every family at a stipulated price in silver, or for a determinate measure of some kind of grain; and the sort of knowledge which was thus to be obtained, being so generally and so anciently diffused in the colony, may, as has been remarked, have contributed its part towards forming amongst the people that litigiousness of disposition, by which even to this time they continue to be distinguished. The fondness, whether proceeding from this, or from some other cause, that is discernible among the people of Connecticut, for settling even their most trifling disputes according to law, while it paves the way for a sufficient employment to a numerous body of lawyers, necessarily gives but an unfavourable impression of their national character. The disposition, however, it is to be observed, is now by degrees subsiding, and what is hardly of less consequence for the advancement of internal peace and harmony, is the abatement which has also taken place in the rage that formerly prevailed here for theological disputation. It would have required perhaps a more particular observation than is often given to such matters, to have ascertained whether the earlier or the more recent character of this people in that latter respect has been materially dependent on any thing in the peculiar forms of their church government. It is of more consequence to remark, that these seem, upon the whole, and in general, to be sufficiently in unison with the republican nature of the civil establishment of the state. While, according to them, each congregation or church has its separate jurisdiction, claiming authority to choose its own minister, to exercise judgment, and to enjoy religious institutions within itself, they yet connect themselves in associations, to which is committed the power of licensing candidates for the ministry, of consulting for the general welfare, and of recommending, though not of enforcing, particular measures for the benefit of the churches. Of such associations there are eleven in the state, which are in like manner combined under one more general association. The number of churches altogether upon the congregational model is said to amount to about 200. Though the numbers attaching themselves to distinct religious sects in this state be not considerable, that is not the consequence of any impediment being placed in the way of such variety of profession, the principle that is acknowledged in this respect being in fact that of making the sole ground of exception, or exclusion against any particular tenets, that they are inconsistent with the peace of society. The public proceedings of this state are in general conducted with calmness and candour, and there seems to be every where enjoyed in it a competent share of political tranquillity. Its laws, before so well adapted to the condition and circumstances of a colonial government, have been yet farther and very judiciously simplified, in the revision to which they were subjected since the peace.

In the years 1675 and 1676, great distress and confusion were brought upon this colony, in consequence of the destructive inroads of the enraged savages, with different tribes of whom in the neighbourhood it was then engaged in war. In 1684, it very narrowly escaped the loss of its charter; but when it was intended that it should in this respect have been subjected to the same fate, which actually befel some of the other states in its vicinity, it owed its security to the artful conduct of one of the citizens, who, as the charter was on the point of being delivered up, buried it under an oak tree in Hartford, where, having remained till the danger was over, it was afterwards dug up and reassumed. At the close of the revolution, Connecticut ceded all her charter claims west of Pennsylvania to Congress, reserving only a tract of land as wide as the state, and 120 miles in length, bounded on the east by the western line of Pennsylvania, and north by lake Erie, and containing nearly four millions of acres. Congress accepted the cession, on which basis accordingly the title of Connecticut to the reserved lands is fully established. This state has been very happily distinguished, in having, almost from the period of its first establishment, had the benefit of a succession, uninterrupted or nearly so, of governors, eminent in a high degree at once for their religious character, and their political accomplishments. Population in 1811, 261,727. See Morse's *American Geography;* Thompson's *Alcedo*, vol. i.; and Peuchet *Dictionnaire de la Geogr. Commerçante.* (K)

CONOBŒA, or Conopea, a genus of plants of the class Didynamia, and order Angiospermia. See Botany, p. 250.

CONOCARPUS, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, p. 155.

CONOID, is the name of a solid, formed by the revolution of a conic section about its axis. Thus, if the conic section is a parabola, the resulting solid is called a *parabolic conoid*, or *paraboloid*; if a hyperbola, a *hyperbolic conoid*, or *hyperboloid*; if an ellipse, an *elliptic conoid*, a *spheroid*, or an *ellipsoid*. (*w*)

CONON. See ATHENS, vol. iii. p. 32.

CONOPS. See ENTOMOLOGY.

CONOSPERMUM, a genus of plants of the class Tetrandria, and order Monogynia. See BOTANY, page 130; and Brown's *Prodromus Plant. Nov. Holl. et Ins. Van Diem.* p. 368.

CONOSTYLIS, a genus of plants of the class Hexandria, and order Monogynia. See BOTANY, p. 196; and Brown's *Prodromus Plant. Nov. Holl.* &c. p. 300.

CONSANGUINITY. See MARRIAGE.

CONSCIENCE, is that principle, power, or faculty within us, which decides on the merit or demerit of our own actions, feelings, or affections. It has been called the *moral sense* by Lord Shaftesbury and Dr Hutcheson. This appellation has been objected to by some; but has been adopted and defended by Dr Reid, who says, "the testimony of our moral faculty, like that of the external senses, is the testimony of nature, and we have the same reason to rely upon it:" (*Active Powers*, p. 242.) He considers conscience as an original faculty of our nature, which decides clearly, authoritatively, and instantaneously, on every object that falls within its province. "As we rely," says he, "upon the clear and distinct testimony of our eyes, concerning the colours and figures of the bodies about us, we have the same reason to rely, with security, upon the clear and unbiassed testimony of our conscience, with regard to what we ought and ought not to do."

Without, in the slightest degree, questioning the utility and authoritative influence of conscience, we must be allowed to think, that Dr Reid is unfortunate in illustrating its power by the analogy of the external senses. With regard to the intimations received through the organs of sense, there can be no difference of opinion, and there can be no room for argument. They give us at once correct information, which reasoning can neither invalidate nor confirm. But it is surely impossible to say as much for the power of conscience, which sometimes gives the most opposite intimations with regard to the simplest moral facts, and which requires to be corrected by an accurate attention to the established order of nature, or to the known will of God, before we can rely with confidence on its decisions.

It does not appear, that conscience can with propriety be considered as a principle distinct from that which enables us to pronounce on the general merit or demerit of moral actions. This principle, or faculty, is attended with peculiar feelings, when we ourselves are the agents: we are then too deeply interested to view the matter as a mere subject of reasoning; and pleasure or pain are excited, with a degree of intensity proportioned to the importance which we always assign to our own interests and feelings. In the case of others, our approbation or disapprobation are generally qualified, sometimes suspended, by our ignorance of the motives by which they have been influenced; but, in our own case, the motives and the actions are both before us, and when they do not correspond, we feel the same disgust with ourselves that we would feel towards another, whose motives we knew to be vicious, whilst his actions are specious and plausible. But in our own case, the uneasy feeling is heightened in a tenfold degree, because self-contempt and disgust are brought into competition with the warmest self-love, and the strongest desire of self-approbation. We have then something of the feelings of a parent, who knows the worthlessness of the child he loves, and contemplates with horror the shame and infamy which might arise from exposure to the world.

Conscience, then, cannot be considered as any thing else than the general principle of moral approbation or disapprobation applied to our own feelings or conduct, acting with increased energy, from the knowledge which we have of our motives and actions, and from the deep interest which we take in whatever concerns ourselves; and we do not think that they have deserved well of morals or philosophy, who have attempted to deduce our notions of right and wrong from any *one* principle. Various powers both of the understanding and of the will, are concerned, in every moral conclusion; and even in those cases where we decide with instantaneous promptitude, the decision is the result of a long induction, rendered familiar, and almost imperceptible, by habit.

We conceive, however, that the Author of our nature has furnished us with infallible principles of judging concerning right and wrong, in giving us certain instincts and feelings, and in establishing a certain order and course of nature, to which these instincts and feelings are adapted. When we see any person acting in direct opposition to the principles and feelings common to human nature, or violating that order of things which God has evidently appointed, we are compelled to pronounce that he is acting wrong; and were all our feelings as simple as instincts, and our knowledge of the order and constitution of things complete, we would need no other rule of duty, but would be led, with infallible certainty, to that line of conduct most conducive to individual and public happiness. This, however, is far from being the case; our feelings are irregular and complex; the designs of providence are not always readily perceived; and a long induction of particulars is frequently necessary, before we can pronounce, with confidence, respecting the merit or demerit of certain actions. With regard to some, indeed, the light of nature can never lead us to a satisfactory conclusion. From this view of the subject, it is evident that a train of reasoning is either actually employed, or imperceptibly implied in every moral decision; and conscience seems to be nothing else than reasoning applied to morals, with a particular reference to our own interests and feelings.

In this view, it will appear that the common language on the subject is pretty correct, and that conscience may, with sufficient propriety, be called the voice of God, as it proclaims his will, after it has been ascertained by a reference to the constitution of our nature, to the economy of providence, or to the light of revelation.

Conscience often acquires a powerful mechanical influence from habit, and frequently inflicts great uneasiness when we deviate from customary though indifferent actions. But it derives its chief and most salutary influence from the consideration of our being continually in the presence of God, and accountable to him for all our thoughts, words, and actions. A conscience well-informed, and possessed of sensibility, is the best security for virtue, and the most awful avenger of wicked deeds; an ill-informed conscience, is the most powerful instrument of mischief; a squeamish and ticklish conscience, generally renders those who are under its influence contemptible and ridiculous.

——— Hic murus aheneus esto,
Nil conscire sibi, nulla pallescere culpa. (*g*)

CONSCIOUSNESS, denotes "the immediate knowledge which the mind has of its sensations and thoughts, and, in general, of all its present operations."

Such is the definition given by Mr Stewart in his *Outlines of Moral Philosophy*, and generally adopted by modern writers on pneumatology, who limit the word to the present operations of the mind, and find fault with Mr Locke, who talks of the consciousness of past feelings and actions. "Of all the present operations of the mind," says Mr Stewart, "consciousness is an inseparable concomitant."

There does not appear to be much reason for this restriction: for certainly consciousness is also an inseparable concomitant of all mental operations which are the objects of memory. The remembrance of past thoughts and sensations, if unaccompanied by consciousness, would be viewed in the same light as the recorded journal of another's sentiments and feelings; and we would consider ourselves as no more accountable for them than for those which we meet in the records of history. The memory retains past thoughts and sensations; consciousness stamps them as our unalienable property.

But is it certain that consciousness accompanies all the present operations of the mind? Does the mind never act, on any occasion, but when we are sensible of it? Would it not be more correct to say, that consciousness necessarily accompanies all the *sensible* operations of the mind, whether they relate to present or past thoughts or sensations? In fact, consciousness seems to be that peculiar quality which constitutes *animality*; which enables animals to perceive and feel, and distinguishes them from those beings which are destitute of life, and organization. Without it, we would have no evidence that the mind thinks at all, and we could have no perception of external objects.

The belief with which consciousness is attended, has been considered as the most irresistible of any; insomuch that this species of evidence has never been questioned: and yet, as Mr Stewart well observes, it rests on the same foundation with every other kind of belief to which we are determined by the constitution of our nature.

There seems to be no good reason for distinguishing the belief arising from consciousness, from the other kinds of belief which necessarily result from the constitution of our nature. Consciousness attends every species of belief, and every feeling of the mind; is in itself perfectly passive, merely reporting what is felt, and giving notice of the impressions received through the medium of the senses and the faculties.

"We cannot properly be said," says Mr Stewart, "to be conscious of our own existence; our knowledge of this fact being necessarily posterior, in the order of time, to the consciousness of those sensations by which it is suggested."

Now, with due deference to such great authority, we are inclined to think, that the consciousness of our sensations and the consciousness of our existence are simultaneous; that we cannot be conscious of feeling without being conscious of existence. The knowledge of our existence is surely not a matter of reasoning; it is forced upon us irresistibly; when we know we feel, we know we exist; and if any man is disposed to doubt his existence, we should think it very idle to attempt to convince him. Des Cartes removed his doubts on this important subject, by the famous maxim, *cogito ergo sum;* if he meant to say, that a thinking being necessarily exists, the argument is extremely absurd, as it assumes the thing to be proved: but if he meant to affirm that the knowledge of our sensations, and the knowledge of our existence, are simultaneous and identical, we conceive that he is perfectly right; and that the consciousness of thought and feeling, gives an instantaneous, irresistible evidence of existence.

Mr Locke conceived that we derived our notion of personal identity from consciousness alone; it is from consciousness and memory that we acquire this idea. See Logic and Metaphysics. (*g*)

CONSECRATION, is the act of solemnly devoting, or setting apart, certain persons, places, and things, to religious duties or purposes. This act, though it has frequently been accompanied with superstitious, absurd, and even impure rites, has its foundation in a principle of reverence for the Deity, and a conviction of the propriety of embodying that reverence in suitable expressions of outward devotion. Among every people, accordingly, however remote from each other, and however dissimilar in character or worship, the obligation of such acts has been felt and recognised. So strong, indeed, is this principle, and so universally does it operate, that, not to mention the Jews, who were divinely commanded to count their first born, whether of men or of cattle, and the first fruits of the earth, sacred to Jehovah; the Greeks, Romans, Egyptians, Persians, Hindoos, and all other heathen nations, have uniformly considered particular persons, animals, plants, rivers, mountains, groves, or caverns, &c. as naturally consecrated to the service or residence of particular deities. But besides this *natural* consecration, as it may not improperly be termed, the consecration of individual persons, places, and things, has formed an important part of worship under almost every form of religion, and has been attended with peculiar solemnities and ceremonies. To some of these we shall now shortly advert.

The consecration of Aaron and his sons to the priestly office, began with an ablution of water, by which they were ceremonially purified; they were then anointed with precious oil, compounded of various costly and fragrant spices; after which they were clothed in the sacerdotal robes. These were eight; four common to all the priests, and four peculiar to the high-priest. The former were the linen drawers, the coat, the girdle, and the turban, all of which, especially in the case of the high-priest, were richly embroidered and adorned with jewels. The latter wore the robe of a blue colour, splendidly fringed, and ornamented with golden bells; the ephod, or short cloak, on the shoulders, fastened by two buttons of onyx or emerald, having the names of the twelve tribes engraven on them; the girdle, on which were the "breast-plate of judgment," studded with four rows of jewels set in gold, and the Urim and Thummim, with the names of the 12 patriarchs graven on it also; and, lastly, the holy crown of gold, having this inscription, "Holiness unto the Lord." The ceremony was concluded by the sacrifice of several animals, some of the blood of which was sprinkled on the tip of the right ear, the thumb of the right hand, and the great toe of the right foot of the priests who were consecrated, certain parts of the sacrifices being at the same time put into their hands. From this last circumstance, the consecration of the ordinary priests was said to be "by *filling the hand*," which, from any thing that appears to the contrary, was the only solemnity observed at their admission into office. It is equally uncertain whether all these ceremonies were repeated at the instalment of every new high priest, or whether he was merely invested with the pontifical habit.

Of the manner in which the consecration of priests among the ancient Greeks was conducted, we have no precise information; but Manilius and Prudentius have described the ceremonies with which the inauguration of particular pontiffs among the Romans was accompanied. "According to the latter," says the learned author of *Indian Antiquities*, "the Taurobolium, a ceremony in which the high-priest of Cybele was consecrated, might be called a baptism of blood. In this dreadful and sanguinary ceremony, the high-priest, about to be inaugurated, was introduced into a dark excavated apartment, adorned with a long silken robe and a crown of gold. Above this apartment was a floor perforated in a thousand places with holes like a sieve, through which the blood of a sacred bull, slaughtered for the purpose, descended in a copious torrent on the inclosed priest, who received the purifying stream on every part of his dress, rejoicing to bathe with the bloody shower his hands, his cheeks, and even to bedew his lips and his tongue with it. When all the blood had run from the throat of the immolated bull, the carcase of the victim was removed, and the priest issued forth from the cavity a spectacle ghastly and horrible, his head and vestments being covered with blood, and clotted drops of it adhering to his venerable beard. As soon as he appeared before the assembled multitude, the air was rent with congratulatory shouts;" and he was saluted by their acclamations with the title of *Pontifex*. *Maurice*, vol. ii. p. 196.

By the Greeks, all dead persons were thought to be under the jurisdiction of the infernal deities; and, therefore, no man could resign his life till some of his hairs were cut out, as an offering by which he was consecrated to them, and especially to Proserpine. They were also consecrated by having peculiar honours conferred on their memory, such as celebrating the anniversary of their death, erecting monuments, statues or altars to them, according to the degree of virtue which they were supposed to have attained, or the eminent public services which they had performed. Some were even raised to the level of the gods; in which case their consecration was called θεοποιΐα; and the sacrifical worship given them θυσια, the same term that was used with respect to the greatest of their deities. This latter custom prevailed also among the Romans. Thus Romulus was worshipped as a God, under the name of Quirinus. And hence, afterwards, the solemn consecration (αποθεωσις) of the emperors by a decree of the senate, when they were said to be ranked in the number of the gods; priests, and temples, and altars, on which sacrifices were offered, being assigned to them. The vestal virgins, after having been chosen by lot, or selected according to the pleasure of the high-priest, were consecrated, first by cutting off and burying their hair, and then arraying them in long white robes bordered with purple, and decorating their heads with fillets and ribbons.

In the ancient Christian church, to the canonical consecration, or *ordination* of a *Bishop*, it was required that at least three bishops should be present, two of whom held the book of the Gospels over his head, and whilst one pronounced the blessing, or consecration prayer, the others solemnly laid their hands on his head. He was then conducted by his brethren to his chair or throne, and having placed him in it, they saluted him with a holy kiss. *Presbyters* were consecrated kneeling at the altar, with prayer, imposition of hands, and consignation, or the sign of the cross on the head. In the consecration of *deacons*, the whole service consisted of a prayer by the officiating minister, that God would endow them with suitable gifts, and enable them faithfully to discharge the duties of their office. But imposition of hands, as well as prayer, seems to have been observed in the consecration of *deaconesses*, so early as the time of Cyprian and Tertullian; and consequently long before the establishment of convents, we read of virgins dedicating themselves to the service of religion, by vowing to lead a single life. If they kept their vow till they reached the age of 40, before which their consecration was not reputed valid, they expressed to the bishop their wish of being consecrated, and having gone to the church, and publicly professed their resolution in the presence of the congregation, the bishop, or presbyter at the altar, put on them a particular kind of veil, and a mitre of purple and gold, by which they might be distinguished from all other females. In later ages, when superstition increased, other ceremonies were added, and the *taking of the veil* was the signal of at least the external relinquishment of every secular concern, and of subjection to a life of rigid seclusion from society.

Under the head of the consecration of persons, we may notice, lastly, that of the Pope. This name was given to the ceremony observed at the instalment of every new pontiff, and was conducted in the following manner, till the pontificate of Gregory X. when the present usage of the conclave of cardinals was introduced. Three days after the funeral of the former pope, the cardinals assembled in the Lateran church, and having invoked the Holy Spirit, and celebrated mass, proceeded to elect a successor to him. The election being made, the first cardinal deacon invested the Pope elect in his pontifical habits, and announced the new name which he chose to assume. He was then conducted to the altar, where he prostrated himself, while the cardinals sung the *Te Deum*. They next seated him in a marble chair behind the altar, where the cardinals, bishops, and others were admitted to kiss his feet, and to receive the kiss of peace. After being led to another chair, called the *stercorary*, and seated in it, the choir sung Psal. cxiii. 7, 8, adding this clause, "and that he may possess the throne of his glory;" on the conclusion of which the chamberlain put into his hands three derniers, which he threw to the people, saying, *silver and gold I have none for my pleasure, but what I have I give you*. He then went into the portico, where he was hailed with shouts of acclamation, and his election declared. After this he walked in procession to the basilic of St Sylvester, and there being seated in a chair of porphyry, he received from the prior of that church, the pontifical ferula and keys; carrying which, he again placed himself in another chair, and then returned these insignia of power to the priors, who girt him with a girdle of red silk, and gave him a silken purse of the same colour, in which were twelve precious stones, and a small piece of musk. In this chair he received and returned the salutations of the ministers of the palace, and cast among the people three several times some silver coin, saying, "He hath dispersed, he hath given to the poor, his righteousness endureth for ever." On the following Sunday, attended by all the orders of the sacred palace, and the principal people of the city, he went to the church of the Vatican, and was there solemnly consecrated by the Bishop of Ostia, to whom this function specially belonged. Lastly, he received the papal pall, and was addressed by the Archdeacon in these words, "Receive the pall, which is the plenitude of the pontifical office, to the honour of Almighty God, of the most happy Virgin his mother, of the blessed apostles St Peter and St Paul, and of the Holy Roman church."

With regard to the consecration of *places* among the Jews, we refer the reader to the account which Scripture gives of the solemnities which took place at the erection of the tabernacle in the wilderness, and the temple of Solomon. Among the Greeks and Romans, all religious edifices, whether temples or tombs, were consecrated with the offering up of prayers and sacrifices by the officiating ministers of religion. This was one of the peculiar duties of the Roman augurs; by whom also, sepulchres or burying places, both private and public, and the walls and gates of cities, were solemnly consecrated; but when a temple was dedicated by the magistrates, the presence of the Pontifex Maximus was requisite. At the consecration of temples, altars, &c. to the celestial gods, the priests bathed their whole body, were clothed in white, made libations by heaving the liquor out of the cup, and prayed with the palms of their hands raised towards heaven. The animals which they sacrificed to them were also white, and in immolating them, their neck was bent upwards, the knife was applied from above, and the blood was sprinkled on the altar or received into cups. But when consecrations were made to the infernal deities, the priests were dressed in black; they only sprinkled their body with water, threw the cup into the fire, and prayed with their hands turned downwards, at the same time beating the ground with their feet. In this case the victims were likewise required to be black; and were killed with their faces bent to the earth, the knife being applied from below, and the blood allowed to pour into the surrounding trench or ditch. By the Greeks, sepulchres and graves were consecrated, by being adorned with parsley, amaranthus, lilies, roses, myrtle, &c. woven into garlands, which were suspended on the monuments, or laid on the turf. The grave stones were frequently also perfumed with sweet ointments; and sometimes altars were erected near the sepulchres, on which black and barren heifers or sheep were sacrificed, and libations of honey, wine, milk, water, &c. poured forth.

It is uncertain when the practice of consecrating *Christian* churches was first introduced; but we find it universally prevalent so early as the reign of Constantine. At that period, whenever the building of a church was finished, to render the consecration or dedication of it more solemn and impressive, commonly a synod of the neighbouring or provincial clergy assembled in the newly erected edifice; when the solemnity usually commenced with a panegyrical oration or sermon, consisting chiefly of praise and thanksgiving to God, and sometimes expatiating on the character or memory of the founder, or the splendor and utility of the fabric. They then proceeded to the "mystical service, or the offering of the unbloody sacrifice to God," praying for the peace of the world, the prosperity of the church, and a blessing on the emperor and his family. A similar practice, at least the ceremony of offering up prayers, still prevails in most Christian countries, either at laying the foundation, or at the opening for public worship, of new churches. Under the episcopal form of worship also, church yards or burying places, are, in general, consecrated by reading particular prayers and other religious rites, before they can be canonically used for Christian interment. In England, churches in particular, have always been consecrated with peculiar ceremonies; the precise form of which, however, has always been left to the discretion of the presiding bishop. Yet for introducing a number of Popish rites, at the consecration of certain churches in London, Archbishop Laud was, in 1644, subjected to general indignation; and his conduct on these occasions, even made one ground of his prosecution by the House of Commons.

Various *animals* were consecrated both by the Greeks and the Romans. Among the former, it was common to devote whole herds of cattle, and several kinds of fowls, especially geese and peacocks, to their gods; by giving them their liberty, and strictly prohibiting them from being touched or molested. Nor were fishes overlooked; they sometimes even put necklaces on them, and then turned them loose into the rivers or ponds. In like manner, the ancient Romans consecrated all the cattle that were produced from the first of March to the end of April, a ceremony which was called *ver sacrum;* and mention is made by Suetonius, of the consecration of a great number of horses by Cæsar when he passed by the Rubicon; and by Pliny, of the consecration of a dolphin which belonged to Octavius Anicius.

The consecration of images, statues, and trees among the Greeks, was the same with that of altars. For the poor sort of the people, all that was required was an oblation of sodden pulse, which a woman, dressed in a garment of divers colours, brought in a pot on her head, and offered in sacrifice to the particular deity to which they were dedicated. The more opulent sometimes took a new vessel with two ears, on each of which they bound a chaplet of white wool, and another of yellow on the forepart of it; they then covered the vessel, and poured out before it a libation called *ambrosia,* which was a mixture of water, honey, and all sorts of fruits. But the most usual method of consecrating statues, &c. was by crowning them with flowers, anointing them with oil, in which the act of consecration chiefly consisted; and then offering prayers and libations to them. The water also used at these sacrifices was rendered sacred, by plunging into it a torch taken from the altar. And the armour and spoils taken in war were consecrated, by suspending a part of them in the temples, or on monuments and statues, or by burning a portion of them on the altars. *Magical* consecrations were not unfrequent among the Romans; it being customary for the emperors to offer sacrifices, repeat charms, and place statues in certain situations, with the view of warding off danger from the empire.

The Roman Catholics, besides an immense multitude of superstitious ceremonies employed at the consecration of almost every thing used in their religious service, such as bells, candles, water, oil, images, crosses, rosaries, &c. apply the term *consecration* in a most peculiar sense to the benediction of the elements in the eucharist, by which they are conceived to be instantaneously converted into the real body and blood of Christ. The same term is given to this part of religious worship even among Protestants, the prayer which is offered up by the officiating pastor, before the bread and wine are distributed to the communicants, being usually called the consecration-prayer.

See Jenning's *Jewish Antiquities;* Potter's *Antiq. of Greece;* Adam's *Roman Antiquities;* L'Enfant's *Hist. Council of Constance;* Spelman, *de non temerandis Ecclesiis;* and Bingham's *Origines Ecclesiasticæ.* (*d*)

Consecutive, Consonance.

CONSECUTIVE CHORDS, in Music, imply a succession or repetition of the same consonance in similar motion. Dr Holder has shewn, that this succession of the same chord, in musical passages, where the parts move the same way, either up or down, and not occasioned by the different parts of the composition moving different ways, or one up and the other down, is cloying and disagreeable, and therefore forbidden in concords, by the rules of harmony or counterpoint, and that consecutive discords are not less offensive, so that the rule against consecutive intervals is in reality general; and he remarks, that the many writers on composition who have limited their prohibition to consecutive fifths, octaves, unisons, and fourths, have not duly considered, that it is only the mingling of *major* and *minor* thirds, sixths, &c. in the scale, that allows any of these to be used consecutively, any more than the perfect concords, as they improperly call them, as above-mentioned; and, that consecutive major thirds, or minor thirds, &c. without the mixture of the two, would as strikingly offend, as those against which the prohibition has hitherto been most levelled. When, instead of an immediate succession of the same chord, an alternate, or any other similar succession of the same chords in the scale, occur in ascending or descending diatonically,—the same is called a *sequence*. (ϱ)

CONSONANCE, in Music, is a term for the union or blending of two sounds, produced at the same time, and includes every possible musical interval.

Consonances naturally divide themselves into three important classes, viz. 1*st*, *Perfect* CONCORDS, (see that article,) or such as produce an agreeable and pleasing effect on the ear. 2*d*, *Imperfect*, or tempered, CONCORDS, which never can differ much from some one of the perfect concords, and have rather a pleasing effect, each distinguished by the peculiar characters of the perfect concord to which it belongs, but alloyed or disfigured by an accompanying and disagreeable phenomenon, called BEATS, which are sorts of *wa, wa, ya, ya,* &c. noises, (see that article,) increasing in quickness, as the tempered concord is more and more imperfect, either in excess or defect, until at length these separate and distinct noises, becoming too quick to be separately distinguished, they blend into a faint discordant note, (whenever the beats exceed about $12\frac{1}{2}$ in a second of time,) which again blends with, or forms a consonance, in a certain degree, with the imperfect concord itself; and where the imperfection is a little farther increased, the same degenerates into a most disagreeable flutter and dissonance, as the experiment that we shall presently describe, from the late Dr Robison, will shew, if carefully repeated. And, 3*d*, DISCORDS, or intervals, that have a grating or disagreeable jarring effect on the ear, or a fluttering roughness in some cases, as will further appear below.

The difficulties under which the science of harmonics still labours, for want of any general and characteristic distinction of consonances, into *concords* and *discords*, has been pretty fully shewn in the former of these articles; and we cannot but recommend a careful repetition of Dr Robison's experiment below, with still more perfect and delicately contrived apparatus, as the most likely means, from the contemplation of the effects of all the possible consonances that thence arise, of leading to an extension of our knowledge of the characteristic properties of each of the above three classes of consonances.

Dr Robison's experiment, alluded to above, is to be thus conducted, on a SONOMETER, provided with two strings, and a resined wheel, that can be steadily turned by the foot, or by an assistant, for the purpose of causing both these strings to sound, clearly and smoothly, for any length of time; the moveable bridge to one of these strings should slide with great truth and steadiness, by means of a screw or a rack and pinion, and not strain or force the string out of its position, or sensibly alter its tension in any part. These two strings, being of the same wire and length, when the sliding bridge is nearly, but not quite, drawn back, are to be tuned, by turning their pegs to a perfect unison. Then, *first*, in order to try the effect of flattening this unison, draw the moveable bridge a little further back, and the smooth uniform consonance of the two strings will be at first accompanied by slow *beats*; these, by a little further withdrawing of the bridge, or lengthening of the string, will increase in quickness and disagreeable effect, until, by a further and farther withdrawing of the bridge, they will become too quick to be distinctly counted; shortly after which, they will seem to form a new very deep, though not very loud, sound, varying in its pitch, and becoming more acute as the bridge is farther drawn back; and a rattling flutter, the combined effect of this new sound and the two strings, will succeed; and after that a disagreeable jar.

The bridge may now be returned to its first position, or where a smooth uni-consonance (I) is heard, without any beats that are sensible, however slow; then, the moveable bridge being slowly and gradually moved forwards, at first a slow and by degrees a quicker beating, (like those before described, but beating *sharp*, or increasing the contrary way,) will be heard, and increase in rapidity, as the bridge is advanced, until they can no longer be counted; and at length these will degenerate into a violent rattling flutter, which will soon after, as the bridge advances, become a disagreeable jarring noise. Still advancing the bridge, vile discordant noises will result from the sound of the two strings, until the variable string has been shortened almost $\frac{1}{10}$th of the length of the fixed string, or where a little more than $\frac{9}{10}$ths of the string continues to sound; when a very rapid angry flutter will commence, and which will become rather less rapid and offensive to the ear, as the point $\frac{9}{10}$ths is approached (II′), and the same will then increase, as the bridge advances, until the discordant jar again prevails, and which will continue until $\frac{8}{9}$ths of the string is approached, when a nearly similar flutter will commence and decrease, and again increase as this point (II) is passed by the bridge; the jar beginning again and accompanying the motion of the bridge, until arrived within some distance of $\frac{5}{6}$ths of the fixed string's length, when a flutter and rapid beats will succeed, decreasing in frequency, until at $\frac{5}{6}$ths, or when the minor third (3rd) is sounded, they will cease entirely, and a concord will result, rather agreeable than otherwise, but strongly marked by a mournful melancholy in the expression.

This last concord being sufficiently noticed, the bridge is again to be advanced by slow degrees, and the beatings will commence again, and increase in quickness, and at length flutter; and the same grating dissonance as before will succeed: this will continue until near the point marked $\frac{4}{5}$ths, when the flutter and beatings will again commence, having a peevish fretful expression as they decrease, owing to the advance of the bridge, to the exact point marking the major third (III); when all beating having ceased, the peculiarly enliven-ing and gay character of this concord will be experienced by the hearer; and who will be able to notice the angry and waspish effect of the succeeding beats as the string is shortened, but which will soon give place to a fluttering and jar as before.

When little more than $\frac{3}{4}$ths of the string's length continues to sound, the fluttering and rapid beats will again be heard, and the beats decreasing, will entirely cease at the point marking the minor fourth (4th,) which will be noticed as a soft and agreeable concord. To this, first slow and then rapid beats will succeed, and rapid flutterings, and a jarring noise, nearly as before, until near $\frac{32}{45}$ths of the string, when the flutter will commence again, and decrease, until they are the slowest, and capable of being counted, at the place of the major fourth (IV); after which, as the bridge advanced, they increased again in quickness, and an indistinct and jarring noise succeeds, which will soon again become a flutter that will decrease in quickness, and about one-third more of them in a second will be capable of being counted; then at the major fourth, when the minor fifth (5th) is reached, at $\frac{45}{64}$ths of the string; these flutters will then increase again, and be succeeded by a jarring noise as before.

The flutterings will be heard to commence again as the bridge advances, and pass into a gentle and not unpleasant undulation, and beats that will cease at $\frac{2}{3}$ds of the string, or the major fifth (V), with all the cheering sweetness that characterizes this concord, or union of the sound of the two strings, which will now be found to blend so perfectly, that neither of them can be separately distinguished; after which the slow and rapid beats and flutterings and jar will succeed, as before.

Some time before the bridge reaches the mark for $\frac{5}{8}$ths of the string, the flutter and beats will begin again, and decrease, and cease at the minor sixth (6th) just at $\frac{5}{8}$ths of the string, which will prove a consonance, only pleasant in a slight degree, and of a mournful character. Beatings will then again commence, as the bridge is moved on, and increase to the jarring and dissonance so often before mentioned, which will however again give place to a flutter, when something more than $\frac{3}{5}$ths of the string is sounding, and the beats will sound, and at length vanish at $\frac{3}{5}$ths or the major sixth (VI;) the character of which it will not, perhaps, appear easy to define, otherwise, than as greatly inferior to the Vth in sweetness and to the IIId in gaiety, but possessing, in some degree, both these qualities.

Still advancing the bridge, when near to $\frac{9}{16}$ths, and to $\frac{5}{9}$ths of the string, perceptible changes to flutters will be perceived, at the minor sevenths (7 and 7′), and others more discernible when $\frac{8}{15}$ths of the string is passed by the bridge, and the major seventh (VII,) results from the sounding of the two strings. The discordant jar and noise will succeed, until within some distance of the half of the string, when the violent flutters, and rapid and slower beats, will succeed, decrease, and cease entirely, at the true octave or $\frac{1}{2}$ (VIII;) the treble string being then not at all distinguishable from the bass one, if the strings were at first nicely adjusted to each other, as to loudness, and the wheel has continued to act uniformly on each, during the motion of the bridge.

If the bridge be still further advanced, slow and then rapid beats, and flutters, and jars, will succeed &c. as from the unison, as the various notes of the scale are again repeated an octave higher than before.

This interesting experiment, often repeated on the best contrived and constructed apparatus that can be got, will prove very instructing, as to the nature of consonances in general. (ϱ)

CONSONANTS. See GRAMMAR.

CONSTANCE, or CONSTANZ, the name of a town in the Grand Duchy of Baden, beautifully situated on the Rhine, at the south west extremity of the lake of the same name. The chief buildings and objects of curiosity at Constance, are the cathedral, the gates of which, and its principal altar, are deserving of notice; the convent of the Dominicans, which has been converted into a linen and cotton manufactory; the cidevant college of the Jesuits, which is a beautiful building, and the public magazine, with the hall in which the famous council of Constance was held, from 1414 to 1418; and the two chairs in which Pope John XXIII. and the Emperor Sigismund sat when they attended the council. The house where John Huss was seized is still shewn, and upon the walls is his head carved in stone. It has an inscription under it in German, but the head is almost wholly defaced. The dungeon is also shewn in the convent of the Dominicans, in which John Huss was confined, and the very stone to which he was chained. It is about eight feet long, six broad, and seven feet high. The bridge across the Rhine, the fort of Peterhausen on the opposite bank, the Fauxbourg of Paradise, and the place where they raised the pile on which Huss and Jerome of Prague were burnt, are the only other objects worthy of attention.

This town, which was once of some commercial importance, was neglected by the house of Austria, and fell into decay. In 1776, when it was visited by Mr Coxe, the streets were overgrown with grass, and the town had the appearance of being totally deserted; but after the Emperor Joseph had granted to the Genoese emigrants (June 30th 1785) a number of privileges for settling in Constance, the town increased in importance; and, in 1787, when Mr Coxe again visited it, the new settlers consisted of 70 families or 350 persons, of whom 54 were watch-makers. Population 3000. E. Long. 9° 8′ 15″, N. Lat. 47° 36′ 10″. See Coxe's *Switzerland*, vol. i. p. 19.; and Reichard's *Itineraire de Poche de Allemagne et de la Suisse.* (π)

CONSTANCE, LAKE OF, is the name of a large lake which separates Switzerland from the kingdom of Bavaria. It is generally divided into three parts. The Superior or the upper lake is called the *Boden See*; the middle part the *Bodmer See*; and the lower part the *Zeller See.*

The principal branch of the lake, called the Superior Lake, stretches from Constance towards Bregentz, and is about 35 miles long, and 15 miles in its greatest breadth. It is said to be 350 fathoms deep near Mersbourg. Its depth is increased in winter by the melting of the snows. It is surrounded by gently rising hills, with towns, villages, and monasteries, scattered at their base. At the eastern extremity of the lake is a considerable island, on which stands the town of Lindau, which was once a free imperial city, but was transferred, at the formation of the Rhenish confederacy, to the king of Bavaria, who has fortified it and provided it with artillery stores.

The middle or northern branch contains the small island of Meinau, which is about a mile in circumference, and belonged to the knights of the Teutonic order. The house of the commander is beautifully situated, and commands a fine prospect of the lake. The beautiful island of Reichenau is situated in the Zeller See. See Coxe's *Switzerland*, vol. i. p. 16, 21. (π)

CONSTANTIA. See CAPE OF GOOD HOPE.

Constantine I.

CONSTANTINE I. surnamed the Great, was born at Naissus in Dacia, about the year 272. His father, Constantius Chlorus, who, after the resignation of Dioclesian and Maximian, shared the empire with Galerius, was of an ancient and illustrious Roman family, and nearly allied, by the mother's side, to the Emperor Claudius. Distinguished by the humanity and mildness of his character, as well as by his warlike atchievements, he proved a steady and seasonable friend to the Christians; and while the dreadful persecutions which raged during the latter years of Dioclesian, were inundating the eastern provinces of the empire with blood, the Christians in the west, under the mild government of Constantius, enjoyed comparative tranquillity and protection. Helena, the mother of Constantine, was of low extraction, and is even said to have been the daughter of an inn-keeper. She was divorced by the command of Dioclesian, upon her husband's exaltation to the rank of Cæsar, when Constantius married Theodosia, the daughter of the Emperor Maximian. Constantine was then about eighteen years of age. In his youth he had shewn little inclination to store his mind with useful knowledge; but, possessing a comely figure and a vigorous constitution, his attention was chiefly directed to the acquisition of martial accomplishments. He was dexterous in every manly exercise, and, by his courage and affability of manners, he soon became a very general favourite with the army and people. Instead of following his father Constantius to the west, he had resided principally at Nicomedia in the suite of Dioclesian, and for his signal services in Persia and Egypt, had been raised to the rank of tribune of the first order. His popularity and accomplishments, however, had exposed him to the jealousy of Galerius, who, dreading the opposition that he might one day have to encounter from his talents and his power, used every mean of retarding his advancement, and of detaining him at Nicomedia, that he might keep a strict watch over his conduct. When Constantius, who found his health daily declining, desired his colleague to send his son to him over to Britain, Galerius delayed as long as possible, and at last allowed him to depart with the utmost reluctance. Constantine arrived at York just in time to see his father expire, in 306. He was immediately called to the throne by the voice of the army, and Galerius found himself obliged to acknowledge him as sovereign of all the provinces beyond the Alps, but denied to him the title of Augustus. Constantine at first appeared satisfied with this acknowledgment, and employed himself for some years in consolidating and securing the power which he had already acquired. About a year after his accession, he married Fausta, the daughter of Maximian, who had again resumed the purple. He was not allowed, however, to remain long in peace. The ambition of his father-in-law, who attempted to wrest from him his dominions, soon gave him an opportunity of engaging in active warfare; and Constantine continued his career of conquest, until he found himself without a competitor in the empire. But as the reign of this prince forms such an important æra both in the history of the world and of the church, it would be anticipating here what will be more properly introduced under other articles to enter into any particular detail of the transactions of that period. We may only observe, that during the contentions which then agitated the Roman empire, and in which Constantine bore such a distinguished part, he all along displayed not only the qualities of a consummate general, but also the more rare virtues of a merciful conqueror. His government in the western provinces was particularly marked by prudence and humanity; and his victory over Maxentius was unstained by those indiscriminate massacres, of which Rome had been so often the theatre upon receiving a new master. The family of Maxentius, and his most distinguished adherents, were the only sufferers; and though a greater number of victims were loudly demanded by the people, yet the emperor firmly resisted their clamours, and informers were even discouraged and punished. When Constantine, after the defeat and death of Licinius, saw himself sole master of the Roman world, his unabated exertions were still directed to the safety and tranquillity of the empire, which enjoyed fourteen years of almost uninterrupted peace; and the Christian cause, in particular, experienced the happy effects of his auspicious administration. But though success invariably followed his standard, and no ambitious rival attempted to dispute his authority, yet his domestic peace was disturbed by the most afflicting events; and by the murder of an innocent son, and the execution of a guilty wife, a stain has been left upon his character, which no apology can obliterate. Crispus, the eldest son of Constantine by Minervina, his first wife, was a youth of the fairest promise. He had early displayed his military prowess against the Germans; and the naval victory over the fleet of Licinius at the Hellespont, was owing entirely to his intrepidity and skill. His valour and engaging manners had secured to him the esteem of his father's subjects, and they beheld in him a worthy successor to the great Constantine. The emperor, it is said, could not brook a rival, either in the empire or in the hearts of his subjects; and the accomplishments of Crispus only tended to draw upon him the displeasure and jealousy of his father. While his younger brothers, the children of Fausta, were promoted to important commands, he was kept at home neglected and unemployed; and when Constantine was celebrating at Rome the 20th anniversary of his reign, the unfortunate Crispus was apprehended, and without the form of a trial, secretly put to death. A deed so repugnant to the feelings of a father, and so contrary to Constantine's wonted clemency and justice, has been the occasion of much controversy. To seek for a cause for such atrocity, as has been done by some in his jealousy of the fame of his son, would be to rank him with the weakest and the most degenerate of mankind. It has, therefore, been more justly imputed to the artifices of Fausta, who wished to secure the empire for her own children. She poisoned the ear of the emperor with the most groundless accusations of treachery and disloyalty against Crispus: or, according to some authors, Crispus having refused to satisfy her incestuous desires, she insinuated to Constantine, that her honour had been endangered by the designs of his son. Her perfidy, however, was at last discovered and punished; but the aged emperor was left to bewail his hasty condemnation of the noblest and most virtuous of his children. The death of Crispus could not but excite the indignation of the people. Unable to decide upon the nature of his crime, or the justice of his punishment, they yielded to the first impulse of their feelings. He had been too much the idol of their attachment and hopes to be immediately forgotten; and the mysterious secrecy in which his death was involved, was a sufficient ground with them to suppose him innocent, and to estrange their affections from the emperor, whom they now regarded as the murderer of his son. Constantine felt that his popularity was declining; and, having no personal attachment to the ancient capital, he determined to remove the seat of empire to Byzantium, which, under the new name of Constantinople, soon rose in magnificence and splendour to vie with the mistress of the world. The latter years of his life were chiefly employed in this great undertaking, and in settling the disputes of the church, which, though it enjoyed outward peace and tranquillity, was now distracted by the Arian heresy. His exertions, however, in this last respect, were attended but with very partial success. It is true that Arianism was condemned by the council of Nice, and that the emperor declared his determination to maintain the orthodox faith; but the disciples of Arius still prevailed at court, and Constantine, on his death-bed, received the solemn ordinance of baptism from the hands of Eusebius, bishop of Nicomedia, the professed patron of the Arians. He died in 337, at the palace of Aquyrion, near Nicomedia, whither he had gone for the benefit of the air and the warm baths, in the 65th year of his age, and the 31st of his reign. "The excessive demonstrations of grief," says Gibbon, "or at least of mourning, surpassed whatever had been practised on any former occasion. Notwithstanding the claims of the senate and people of ancient Rome, the corpse of the deceased emperor, according to his last request, was transported to the city, which was destined to preserve the name and memory of its founder. The body of Constantine, adorned with the vain symbols of greatness, the purple and diadem, was deposited on a golden bed in one of the apartments of the palace, which for that purpose had been splendidly furnished and illuminated. The forms of the court were strictly maintained. Every day, at the appointed hours, the principal officers of the state, the army, and the household, approaching the person of their sovereign with bended knees, and a composed countenance, offered their respectful homage as seriously as if he had been still alive. From motives of policy, this theatrical representation was for some time continued; nor could flattery neglect the opportunity of remarking that Constantine alone, by the peculiar indulgence of heaven, had reigned after his death."

The character of this prince has been drawn in such a variety of colours, by different writers, that it is difficult to delineate his portrait with any degree of unsuspicious accuracy. The invectives of the Pagan historians, and the flattery of the Christians, are, in all likelihood, equally removed from the truth; and, were we, according to Cardinal Fleury, * to take his vices from Eusebius, and his virtues from Zosimus, he would have so little of either, that his character would not be worth preserving. But in appealing to more impartial authorities, a tolerable estimate may be formed of those qualities for which this great prince was more particularly distinguished. The general tenour of his administration was marked by wisdom and justice. He was indefatigable in business; and always ready to hear and to redress the grievances of his subjects. As a soldier, he was equalled by none in the disastrous times in which he lived; and from the beginning of his career until he became undisputed master of the empire, he showed, in every enterprize, the most consummate skill and personal valour. His troops were always animated by his example; and, "to his abilities rather than to his fortune," says Mr Gibbon, "we may ascribe the signal victories which he obtained over the foreign and domestic foes of the republic." The early part of his reign, indeed, has been highly panegyrised by this historian, but we have reason to suspect his sincerity, and cannot help believing that his design in doing so was, that he might, with the greater appearance of candour, consign to infamy the memory of the first Christian emperor. "In the life of Augustus," says he, "we behold the tyrant of the republic, converted, almost by imperceptible degrees, into the father of his country and of human kind. In that of Constantine, we may contemplate a hero, who had so long inspired his subjects with love, and his enemies with terror, degenerating into a cruel and dissolute monarch, corrupted by his fortune, or raised by conquest above the necessity of dissimulation." This may, no doubt, be considered more as a rhetorical flourish, than as the grave dictate of historical truth, and therefore is not to be taken in its literal acceptation; but such language is very inconsistent with that impartiality of which this author so often boasts: and allowing even the credibility of every vice with which he has deformed the latter years of Constantine, and by which he has attempted to expose him to ridicule and contempt, it would by no means warrant such a severe and indiscriminate censure. That Constantine in the latter part of his reign was too prodigal of the public money; that the enormous expences which attended his administration, and the stately buildings with which he adorned his new city, could only be supported by an increased taxation, must be acknowledged; that he assumed too much, both in his dress and manners, the state of eastern magnificence, we will also allow; nor will we attempt to palliate even his conduct towards his son Crispus; yet taking into account every failing with which he has been charged, and rejecting all the panegyrics of the Christian fathers in his favour, we would with greater justice give a summary of his character in the words of an ancient Pagan, than in those of the modern which we have quoted above: *In primo Imperii tempore optimis principibus, ultimo mediis comparandus.*

The religious character of Constantine has been equally the subject of controversy and animadversion. Some have attributed his support to the Christian cause entirely to political motives, and maintain, that he was no more convinced of the divinity of Christianity, than he was of the divinity of Paganism; but that he encouraged it, as the most effectual means of uniting mankind under his government. That Constantine shewed the greatest respect for Christianity from his first assuming the purple; that he recommended its doctrines to his subjects; and that he continued his attachment and protection to its disciples until his death, —no one surely will attempt to deny. If an uniform course of conduct, then, be any evidence of inward sentiments, we have the most convincing proofs, that Constantine believed in the divinity of the gospel. Whether his heart was suitably influenced by its sublime truths, is a different question. But there can be no doubt, that he preferred it to every other religious system, when he made it the established religion of the empire. That Constantine might have been induced to become the friend of the Christians, in conformity to the wishes of his dying father, we may believe; that he might have been led to support them, from early prejudices in their favour, or from those feelings of sympathy which are always the attendants of true magnanimity, we can also easily conceive; but

* "On ne se trompera point sur Constantin, en croyant tout le mal qu'en dit Eusebe, et tout le bien qu'en dit Zosime." Fleury *Hist. Eccles.* tom. iii. p. 233.

that a prince should embrace such opinions from political motives, appears to us scarcely within the bounds of probability. When Constantine began his career of ambition, the Christians were an insulted and despised sect. The persecutions, which raged with such fury in the reigns of Dioclesian and Maximian, were still continued under their successors, and exceeded in cruelty all that had ever afflicted the Christian church. The bloody Maximian vowed to Jupiter, that if he was successful in his contest with Licinius, he would extirpate the Christian name; and on a medal of Dioclesian, which was struck at that period, and which is still extant, is this inscription,—*Nomine Christianorum deleto:* the name of Christians being extinguished. The mild Constantius, even when he held the rank of Cæsar in Gaul, was compelled by the edicts of Maximian to destroy the churches, though he continued to respect the persons of the Christians. To espouse such a cause, then, was not the most likely road to the object of his ambition. It inevitably exposed him to the derision and opposition of the Pagans, who composed the armies of his rivals, and perhaps the majority of his own; and could only serve to collect under his standard the few Christians who had escaped the rage of their enemies. Had Constantine, therefore, regarded Christianity, as was done by the learned Pagans of that age, as "old wives' fables," or as a superstition which threatened the republic with ruin, it would have been folly to have hazarded his success by such a step, while by an opposite conduct he could more easily have secured the affections of the Roman people, who were now weary of their tyrannical masters. He must, consequently, have believed in the truth of Christianity, or supposed it at least of equal authority with the polytheism of the Pagans; and it is probable, that he hesitated long before he came to the final resolution of destroying the temples of the gods, and of declaring himself a faithful disciple of the cross. Much has been said respecting the date of his conversion; but this is not a subject for man to explore; for, whether he was suddenly or gradually brought to the knowledge of Christianity, or whether indeed he had ever such views of divine truth as the gospel requires, can only be known to the Searcher of hearts. He had been, no doubt, early taught to revere the name of Christ. In the palace of Constantius were many Christians, and even ministers of the gospel, who openly prayed for the emperor; and the opinions and conduct of such a father could not but have a considerable weight with his intelligent son. Though, when resident at the court of Dioclesian or Galerius, he did not shew, at least was deterred from shewing, any partiality for the persecuted sect, yet as soon as he found himself beyond the reach of their authority, and at liberty to act according to his own judgment, he declared himself the friend of the Christians, by continuing to them that protection which they had enjoyed under his father; and from that period, every victory which he obtained was only an additional triumph to the cause of Christianity. With respect to the luminous appearance of a cross in the heavens, which he is said to have seen with his whole army when marching against Maxentius, and to which, with the heavenly vision of the subsequent night, Eusebius ascribes his conversion, much has been written to little purpose.* We confess, that the evidence for this fact appears to us neither so full nor so satisfactory as could be wished in a case of such a miraculous nature; but though we may hesitate in giving it implicit credit, we can see no reason for rejecting it, as many have done, on the ground of improbability. To them who admit the divine origin of Christianity, and are disposed to believe that God has interposed at any time in behalf of the church, this miracle must appear both credible and proper; for scarcely was there a time, when the importance of the contest called more for such an interposition. But whatever credit be attached to this miracle, it is a well known fact, that Constantine, in one of his first edicts which he published after the death of Maxentius, abolished throughout his dominions the punishment of the cross; and what was formerly an object of horror to every Roman citizen, he rendered a badge of distinction and valour, by placing a cross in the right hand of his own statue at Rome, with an inscription which referred the victory of his arms to the virtue of this sign. "The same symbol," says Mr Gibbon, "sanctified the arms of the soldiers of Constantine; the cross glittered on their helmet, was engraved on their shields, was interwoven into their banners; and the consecrated emblems which adorned the person of the emperor himself, were distinguished only by richer materials, and more exquisite workmanship." Those who are inclined to question Constantine's sincerity in the profession of Christianity, may be referred to the invariable tenor of his government. In all his public edicts, the church seems to be the chief object of his regard. He increased its privileges, honoured its pastors, and attended its worship; and he shewed, that he had in some degree imbibed the mild and forgiving spirit of the gospel, for, while he earnestly recommended to the governors of provinces to extend its influence among his subjects, he declared, that he would compel no one to embrace it contrary to his inclination. He has indeed been charged, and justly too, with many actions very inconsistent with the pure dictates of that religion which he professed; but if this is to be taken as an evidence of his insincerity and dissimulation, the same argument may be applied to some of the most eminent bishops of his own time, and also to many sincere professors of the present day. His delaying to receive the initiatory rite of baptism to so late a period of his life, has been most satisfactorily accounted for. Christianity had considerably degenerated from that simplicity and pure morality, for which it was so eminently distinguished under the apostles. Many superstitious ceremonies and unmeaning forms had crept into its worship; and, as many of its professors had been taught to believe a necessary connection between baptism and the remission of sins, they delayed this rite as long as possible, that they might ascend pure and spotless to the mansions of immortality. In reviewing the character of this prince, we would conclude with observing, with the candid Lardner, "that we should be willing to make allowances in favour of princes, and especially of long reigns. It is next to impossible for human wisdom and discretion, in the course of many years filled

* The fact is thus abridged from Eusebius by Milner: "While he was marching with his forces in the afternoon, the trophy of the cross appeared very luminous in the heavens, higher than the sun, with this inscription, τȣτω νικα, "conquer by this." He and his soldiers were astonished at the sight; but he continued pondering on the event till night And Christ appeared to him when asleep, with the same sign of the cross, and directed him to make use of the symbol as his military ensign. Constantine obeyed, and the cross was henceforward displayed in his armies." Milner's *History of the Church of Christ*, vol. ii. p. 41.

Constantinople.

with action, not to be surprised into some injustice, through the bias of affection, or the specious suggestions of artful and designing people. Though, therefore, there may have been some transactions in this reign which cannot be easily justified, and others that must be condemned, yet we are not to consider Constantine as a cruel prince, or a bad man." See Lardner's *Credibility of the Gospel History*, vol. vii. Gibbon's *Roman Empire*, vol. ii. p. 190, and vol. iii. p. 99, 8vo. Milner's *History of the Church*, vol. ii. c. i. and ii. Esprinchard, *L'Histoire Auguste, ou les vies des Empereurs Romains*, vol. i. p. 520. Mosheim's *Eccl. Hist.* vol. i. p. 320. (*p*)

CONSTANTINOPLE, called by the Turks *Stamboul*, the ancient *Byzantium*, and capital of the Turkish empire, stands on the western shore of the Thracian Bosphorus. This strait, which divides Asia from Europe, and joins the Euxine with the Mediterranean Sea, affords an easy communication with the most fertile regions and principal nations of the three continents; and points out Constantinople as admirably situated for being the centre of a rich and extensive commerce. † The situation of the city is also equally remarkable for beauty and security. It is built upon seven hills, which appear to rise above one another in beautiful succession; and has the figure of an unequal triangle, with the base facing the west, and the obtuse angle jutting into the sea. Its northern side is bounded by an arm of water navigable for several miles, and which forms a safe and commodious harbour. On the south, it reclines upon the sea of Marmora; and towards the land it is defended by a strong wall, with a triple fortification 18 feet distant from each other. This wall, notwithstanding the effects of time, and the many memorable sieges which the city has sustained, is still in great preservation. It is flanked with lofty towers of various shapes, and has five gates, with stone bridges over the foss, which is 25 feet wide, and, in many places, decorated with trees of great beauty and variety. The most remarkable of these gates, though the most ruinous, is the Porta Sancti Romani, which first yielded to the barbarous valour of the Turks, and where the emperor Constantine Paleologus, its magnanimous defender, was slain. The wall is composed of large flat bricks and freestone laid in alternate courses; and the internal arcades and rooms in the towers are all of brick, and of most curious construction. The fortifications towards the sea are in a more decayed state, and are partly destroyed. At the southern extremity of the city is a small fort, called by the Turks Yeddikuli, or the seven towers. It was built by some of the Greek emperors, probably John Zimitzes, in 1000, and had originally only four towers. Other three were added in 1458 by Mahomet II., who also rebuilt a great part of it, and converted it into a state prison. This fort forms a tolerably regular pentagon; and the area of the whole inclosure, according to Dr Pouqueville, is about 5500 square toises. All the five angles were formerly flanked by towers with conical roofs, which give them a clumsy and mean appearance; but of these one was thrown down by an earthquake in 1768, and another is falling fast into decay. On the front, towards the west, stands the ancient triumphal arch of Constantine, with a marble tower on each side. Both these towers are enormous masses with platforms at the top, but are only between 80 and 90 feet high, and scarcely overtop the adjacent walls. This place is now chiefly used by the Turks for confining the ministers and ambassadors of the powers with whom they happen to be at war.

Situation.

Walls and gates.

Fort of the Seven Towers.

The walls of Constantinople inclose an area of about 2000 acres, and its total circumference is from twelve to fourteen English miles. The summits of its hills are covered with innumerable mosques and baths, intermixed with lofty cypresses; and their declivities are crowded with habitations and terraced streets. The multitude of houses painted of different colours, the gilded domes, and the elegant and slender minarets, crowned by the shining crescent, impress the beholder with a high idea of its magnificence and splendour. The interior of the city, however, but ill corresponds with the beautiful *coup d'œil* which it presents at a distance. "To say something of Constantinople, in general," says Mr Sandys, "I think there is not in the world any object that promiseth so much afar off, and entered, that so deceiveth the expectation." It consists of an assemblage of dark and narrow streets without names, badly paved, and choked either with dust or mud. The office of scavenger is left entirely to the dogs and vultures, which prowl about during the night; and the only time that the streets are tolerably clean is after rain, which, owing to their declivity, washes away and carries off the filth. The houses are constructed of wood and earth, and are, in general, low and mean, full of unglazed windows, and without chimneys. The best apartments are always appropriated to the Harem, and are remarkable for the neatness and elegance of their furniture. None of the houses, however, are allowed to exceed twenty-six feet in height, which gives the streets a very mean appearance. Indeed there is scarcely a tolerable street in all Constantinople; and if the Turks claim for their capital the appellation of new Rome, it must be owing entirely to its public edifices, which being interspersed among its crowded lanes, diffuse over it an air of gloomy magnificence.

Streets.

Houses.

On the eastern promontory, stands the palace and gardens of the Seraglio, which cover one of the seven hills, and occupy the site of the Byzantine republic. This spot was judiciously chosen by Mahomet II. for his imperial palace. In 1478, he enclosed with lofty walls an area of about 150 acres, which he destined to be the seat of Turkish jealousy and despotism. Succeeding Sultans have beautified and enlarged its buildings; and the whole space is now covered with detached suites of apartments, mosques, baths, gardens, and cypress groves. So many glittering domes, rearing their lofty heads above the verdant foliage and painted terraces, produce at a distance a very beautiful effect, which, however, is entirely lost upon a nearer inspection; for they are huddled together without symmetry or order. The principal entrance is on the west, through the Baba-hoomajin, or Sublime Porte, which is built of marble, and has a very heavy appearance. It is here that state delinquents are decapitated, and their heads exposed for three days. In front of this gate is an extensive and irregular area, the ancient Augusteum, having in the centre a richly ornamented fountain built by Achmet III.; and on the north the magnificent church of St Sophia. Within is the first court, which contains

Seraglio.

† "Est in Europa; habet in conspectu Asiam. Ægyptum Africamque a dextra: quæ tametsi contiguæ non sunt, maris tamen navigandique commoditate veluti junguntur. A sinistra vero Pontus est Euxinus." *Busbequius*, Epist. i. p. 64.

Constantinople. the mint, and the vizier's divan; and opposite is the Baba-Salem, or gate of Health, which leads to the second court, where is the audience chamber, in which foreign ambassadors are received by the Sultan in person. In this chamber is the throne, which resembles a large four-posted bed; the posts are inlaid with precious stones; the canopy is of velvet, fringed with jewels; and the cushion upon which the sovereign sits, is composed of a massy embroidery of pearls. The gate which terminates the second court, is called Baba-Saadi, or the gate of Happiness, and through which no stranger is allowed to pass. Beyond it are scattered a rich profusion of buildings, terraces, and flower gardens, where are immured above five hundred unfortunate females, devoted to the pleasures of a single master. Seldom has love or pleasure been known to reside within these abodes of luxury. Whatever can minister to the vanity of its inhabitants is amply provided: sumptuous apartments, splendid dresses, and a variety of amusements; but they are tormented with the most corroding passions, and are incessantly engaged in intrigues of rivalship. Many are doomed to waste their beauty in vain attempts to please a master, who often receives them with disdain; and others are sacrificed, by the application of poisonous drugs, to the jealousy of a rival. The furniture of the palace is distinguished more by its richness than its variety. It consists chiefly of the sofa spread round the room, the carpets, and the mirrors. The walls are wainscoted with jasper, veneered ivory, and mother-of-pearl; and the hangings are of silk and cloth of gold, with fringes strung with pearls, and inferior jewels. The gardens are laid out in a very inferior style, more after the taste of Holland than of any other country. "Various and very despicable *jets d'eau*," says Dr Clarke, "straight gravel walks, and borders disposed in parallelograms, with the exception of a long green-house filled with orange trees, compose all that appears in the small spot which bears the name of the Seraglio gardens." The library of the palace is said to contain several valuable manuscripts, both Greek and Latin, as well as Oriental. Many of them are kept in confused heaps, without either catalogue or arrangement; and some have pretended, that the original gospel of Matthew in Hebrew, and the last books of Livy and Diodorus Siculus, are among the number. This, however, is merely conjecture, which rests upon very questionable grounds. It is said, that Pope Nicholas V. offered 5000 sequins for the gospel of Matthew, and that the Grand Duke of Florence made an offer of 5000 piasters, which was doubled by the Bailo of Venice, for the MSS. of Livy, but neither of them were produced. It is impossible, indeed, to ascertain, with any degree of precision, the real contents of this library, as it is inaccessible to Christians.

[Ol]d Seraglio. The old Seraglio occupies the third hill, which is nearly in the centre of the city, and is surrounded by a lofty wall about a mile in circumference. It is now appropriated to the reception of the wives and harems of the deceased, or deposed sultans. They are here treated with considerable distinction, but are secluded for life, as it is considered indecent that a slave, who has enjoyed the favours of a Sultan, should pass into the possession of another man. Such of the young ladies of the harem, however, as are declared to have been unknown to him, are generally united to some of the courtiers of his successor.

St Sophia's Church. Among the numerous mosques and public edifices which adorn Constantinople, the first place, both for magnificence and elegance of architecture, is due to the church of St Sophia, which seems to have served as a model for all the rest. (See Civil Architecture, vol. vi. p. 625. and Plate CLXXIII.) It stands, as we have already observed, on the north side of the ancient Augusteum, near the principal gate of the Seraglio. It is the first erected Christian church now existing, and was built by Constantine the Great, and dedicated to St Sophia, or the "Inspired Wisdom." During the reign of Justinian, however, it was completely destroyed by fire in a popular sedition, when that emperor ordered it to be rebuilt with greater sumptuousness and elegance, under the inspection of the most celebrated architects of the time, Anthemius of Tralles, and Isidorus of Miletus. It was finished in eight years and five months, and, according to the lowest computation, at the expence of one million sterling. Most travellers, who have visited Constantinople, have given a description of this church, but in general with such confusion or obscurity of narration, that it is difficult, from their statements, to convey to our readers any correct idea of its several parts; and it has been very justly observed by an intelligent and classical traveller of the 17th century; "a long labour it were to describe it exactly, and having done, mine eyes that have seen it would but condemn my imperfect relation." (Sandys' *Travels*, p. 24.) The most scientific idea of its architecture, will be derived from consulting Grelot *Voyage de Constantinople*, and the engravings published by Banduri in his *Imperium Orientale*. It is said to be built in the form of a Greek cross with a dome, which is constructed with so small a curve, that the perpendicular concavity does not exceed one-sixth of the diameter. This flatness is, in general, much admired; and, "if the great vault of heaven be the idea intended," says Mr Dallaway, "with a happier imitation than in St Peter's at Rome." The outward appearance of this building, however, owing to the heterogeneous additions which have been made to it, presents only a pile of unsightly masses. It was propped with two immense buttresses by Andronicus in 1317; and four minarets have been added by the Turks, which, however, give it an air of lightness that it would not otherwise possess. Its exact length from east to west is 269 feet, and its breadth 243. The principal vestibule, which is on the west, is 28 feet wide, and has nine doors of bronze, magnificently wrought in alto relievo. The interior of the church, though many of its ornaments have been defaced by the Turks, still retains much of its ancient grandeur. The grand dome has a regular tier of windows, and rests upon four arcades, connected with as many cupolas, which blending with the principal one, forms an immense expanse of roof. The whole has been originally ornamented with mosaic work upon a golden ground; but the Mahometans have covered it completely over with white wash. The spacious floor is entirely devoid of seats and benches, and is covered with the richest carpets; and from the roof are suspended innumerable lamps of coloured glass, intermixed with globes of crystal, ostrich eggs, and ornaments of gold and silver, which, when illuminated, give a grand effect to the stupendous concave. Among the numerous pillars which adorn this mosque, are six of green jasper, which once supported the roof of the temple of Diana at Ephesus; and eight of porphyry, that had been placed by Aurelian in the temple of the Sun at Rome, but were removed hither by Constantine. St Sophia was dedicated to Islamism by Mahomet II., and still retains the revenue which it enjoyed when a Christian church. This revenue, which arises from a species of tenure called *vacuf*, in some measure analogous to

Constantinople.

church lands with us, amounts to nearly 3000*l.* a year, which is employed in keeping the mosque in repair, and in paying the stipends of the officiating imams.

Mosques.

Besides St Sophia, there are several other very handsome mosques, many of which were originally Greek churches. The imperial mosques, especially those which have been built by particular Sultans, appear nearly equal to that of St Sophia, though, upon a nearer inspection, their inferiority is obvious. Of these, the principal are, that of Mahomet II. which crowns one of the seven hills, and stands upon the site of the celebrated church of the apostles, built by Theodosia the wife of Justinian; that of Achmet I. which was constructed in 1610, at an enormous expence, and has six minarets of extraordinary height and beauty, but the internal embellishments are gaudy and irregular; that of Bajazet, in which are twenty columns of remarkable size and value, viz. ten of verd antique, four of jasper, and six of Egyptian granite; that of Solyman II. which is esteemed of superior symmetry and elegance, and was constructed from the materials of the church of St Euphemia at Chalcedon. The mosque of Laleli, or the Tulip, is small, but very elegant, and was built by Sultan Mahmood in 1753. It is wainscoted with veneered marble, and has two large embroidered tablets, on which are represented the cities of Mecca and Medina. Every mosque has, in general, a large area in front, surrounded by a lofty colonnade of marble with gates of wrought brass, and in the centre are fountains of polished marble. Adjoining to each is the sepulchral chapel of its founders, where his remains are deposited, and sometimes such reliques as are worth preserving. In that of Sultan Mahmood, is the Koran written with his own hand. These mosques have also an hospital and academy attached to them, where students are educated and maintained upon the foundation. Of the Christian churches in this city, the Greeks have twenty-three, including the patriarchal church; and the Armenians three. There are six Roman Catholic convents, and several Jewish synagogues, also a Swedish Lutheran church.

Atmeidan, or horse-course.

Among the antiquities of Constantinople, the Atmeidan, or horse-course, deserves particular attention. It is the ancient circus, or Hippodrome of the Greeks, so constantly occupied by public games and exhibitions, and it still continues to be the scene of most of the public ceremonies and processions of the Turks. The area is about 250 paces in length, and 150 in breadth, but its sides are very irregular. On the east is the mosque of Sultan Achmet, and on the west the ruins of a large building, supposed to have been the questor's palace, part of which is now appropriated to the reception of lunatics, and another part is used as a menagerie. Of the numerous statues and obelisks with which the circus was anciently ornamented, during the Greek empire, few have escaped the fury of the Turks, and the earlier ravages of the French and Venetians. An obelisk of superior workmanship, which stands near the centre of the area, is composed of a single block of Egyptian granite 60 feet high, and is inscribed with Egyptian hieroglyphics. It was brought from Thebes by Theodosius the elder, and erected at Constantinople, by means of curious machinery, in 32 days. The base is of white marble, seven feet in height, and sculptured with bas-reliefs representing the emperor presiding at the circus games. The Greek and Latin inscriptions are now almost sunk under ground, or totally obliterated. Towards the south end of the area is the serpentine pillar, a singular fragment of antiquity, which is confidently said to have once supported the golden tripod which was consecrated by the victorious Greeks in the temple of Delphos, after the defeat of Xerxes. It is of wreathed brass, about twelve feet high, and formerly terminated at the top, with figures of three serpents rising from the pillar, and with necks and heads forming a beautiful triangle. The lower jaw of one of the serpents was shattered by Mahomet II. with a stroke of his battle-axe; and we are told by De La Mottraye, that during his stay in Constantinople, in the year 1700, the other two heads were stolen by some unknown depredator, but who was generally suspected to be a servant of the imperial ambassador. Chishull, however, mentions in general, that they were broken off by some attendants of the Polish ambassador who lodged in the neighbourhood. The Atmeidan still serves as a place of equestrian exercise; and it is here that the Turks practise upon horseback, a kind of military game called *djirit,* to which the young men of fashion are trained from their childhood as a necessary accomplishment. This game consists chiefly in darting at each other, with great violence, the djirit, a white wand of about four feet in length; and their skill is shewn by avoiding the stroke, in pursuing their adversary, in checking their horses in full gallop, or in stooping from them to reach the djirit from the ground. This exercise requires great agility and strength, and is both fatiguing and dangerous.

Aqueduct of Valens.

The other remains of Grecian architecture are the aqueduct of Valens, and some triumphal columns. The former, which conducts the brook Hydrale from Belgrade, was constructed with materials from the walls of Chalcedon; and connects the third and fourth hills by more than 40 arches. It was repaired in 570 by Justin the younger, and almost completely renewed by Solyman the Magnificent. The columns still to be seen are those of Constantine, Marcian, and Arcadius. Of the latter, however, the base only remains, which is 14 feet high, but all the sculpture is defaced. The shaft, which was covered with a series of bas reliefs representing the victory of his father Theodosius over the Scythians, was, on account of its ruinous state, taken down in 1695. That of Constantine is the most perfect, and is called by the Turks "the burnt pillar," having suffered greatly from frequent conflagrations. It stands upon a pedestal of white marble nearly twenty feet high, and is composed of huge blocks of porphyry about 33 feet in circumference, with circles of embossed brass to conceal the joints. On the summit stood a colossal statue of Apollo, in bronze, supposed to have been the work of Phidias, but it is now overthrown, and the porphyry is discoloured and cracked by the fire. The column of Marcian stands in a small enclosure or garden, and is surmounted by a capital of the Corinthian order, which is rather disproportioned to the shaft, and is unclassically rich in ornaments.

Fountains and baths.

As frequent ablutions are commanded by the Koran, and are also required by the exigencies of the climate, there are within the walls of Constantinople 130 public baths; and fountains are to be found in almost every street. The baths of the Greeks were continued by their Turkish conquerors; and those of Zeuxippus, Arcadius, and Eudoxus, were dedicated to the service of the public. Many more have since been erected, but they are all nearly of the same plan; and some of them are very elegant buildings of hewn stone, having the inner chambers paved with slabs of beautiful marble. The use of the bath in Turkey is very different from our method of bathing, and resembles rather the lustra-

Constantinople. tions of the ancients, which is in every respect both more luxuriant and refreshing. The fountains are low square buildings, with leaden roofs. They are, in general, profusely covered with gilding and a variety of colours, and inscribed with verses.*

Bazars. The bazars of Constantinople are very extensive, and form numerous streets, where articles of every description are daily exposed to sale. They consist of lofty cloisters, built of stone, and lighted by domes, which are admirably adapted for the climate, and in summer afford a cool and pleasant retreat. Every trade has its particular quarter; and each dealer has a small shop in front, with a room behind for his wares. In one street, nothing is to be seen but arms of different kinds; another is filled with jewels, diamonds, and precious stones; some are lined with India stuffs, with brocade of silver and gold, while others are set apart for Egyptian minerals and drugs; or for booksellers, who have always on sale an excellent assortment of Arabic, Turkish, and Persian MSS. Whole streets are occupied by shoemakers, furriers, pipe-makers, cooks, or confectioners, &c. each being confined to its distinct district. The different trades are also appropriated to different nations; and each has the proper costume of his respective country or profession, which forms a curious and almost infinite variety of dress and appearance.† Every evening the bazars are shut at an early hour, and no one is allowed to remain but the guard. There are also khans, or hotels, built of stone, and fire proof, where merchants, from all quarters of the empire, who travel with caravans, find ample accommodation both for themselves and their merchandise. The Avret bazars, or woman-market, is held in an inclosed court, surrounded with a cloister and small apartments. Here female slaves, from different countries, are publicly exposed for sale every Friday morning. Those from Egypt and Abyssinia are generally purchased for domestic purposes; while the Georgians and Circassians are reserved for the seraglio, or the harems of the opulent, and are usually sold for several thousand piastres.

Suburbs. The suburbs of Constantinople, which are very extensive and populous, stretch chiefly towards the north beyond the harbour. Of these, the principal are Galata, Pera, and Scutari. *Galata,* which lies on the water side, was built by a colony of Genoese, who, in 1261, obtained from the Greek emperors the privilege of being governed by their own magistrates; and this colony increased so rapidly in commercial consequence, that, before the conclusion of a century, they extorted from Michael Paleologus the liberty of surrounding their city with a strong wall. They soon afterwards became the most determined enemies of the empire, and are supposed to have afforded assistance to the Turks in the last siege of Constantinople. The walls formed a circuit of nearly four miles, but they are now in ruins; and the place is chiefly inhabited by merchants of all nations, who are confounded under the general name of Franks. They prefer it to Constantinople, on account of its vicinity to the harbour, and also because most of the buildings are fire-proof. A Turkish guard is stationed at each of the gates, which are always shut after sun-set, except the one leading to Pera, which is opened at almost any hour of the night, for the accommodation of the Franks, who annually pay a small sum to the chief of the guard for this privilege. *Pera* stands immediately above Galata, and stretches for more than two miles along the summit of a lofty hill. The houses, with a few exceptions, are built of wood and unburnt bricks. The streets, in general, intersect each other, and are narrow, ill paved, and irregularly built. The air, however, is uncommonly healthy, the prospect delightful, and the town is well supplied with water. Pera has long been appropriated for the residence of the corps diplomatiques from the different nations of Europe, who have each of them a palace here; and the inhabitants are judged by the laws, or the ambassador of the nation that protects them. Formerly no person was allowed to build or to reside here, unless such as were attached to these missions; but of late it has become the abode of the most wealthy of the Greeks and Armenians, who find themselves more at liberty here, and less exposed to exactions and insults, than under the government of the Turks. *Scutari,* the ancient Chrysopolis, which lies on the Asiatic side of the channel, is also considered a suburb of Constantinople. It is situated on a sloping ground, and has a very picturesque appearance, from the mixture of trees, houses, mosques, and minarets. It serves at present as a rendezvous and an emporium to the caravans of Asia; but it is chiefly distinguished for its extensive burying grounds, which are the handsomest in the Ottoman empire, both from the luxury of the tombs, and the height and closeness of the trees. These cemeteries extend for some miles on the east and south of the town, towards the sea. The rich Turks of Constantinople prefer this spot to any on the European side, from the belief, which seems to be very generally entertained among them, that their capital will one day be regained by the Christians; and, consequently, they wish to escape the disgrace of having their ashes trodden on by the infidels. To these may be added Tophana, or the cannon foundery, which lies on the north side of the harbour, near Pera, and opposite to the seraglio; and the village of Eyub, which received its name from Eyub, or Job, the standard-bearer of Mahomet, who was killed in the first siege of Constantinople by the Saracens; and to whose memory Mahomet II. having discovered the place of his sepulture by a revelation, erected a mausoleum and mosque.

Environs. The environs of Constantinople, except on the shores of the channel, exhibit, in general, nothing but naked and waste lands, without verdure or inhabitants. Though the soil is every where adapted for various kinds of corn and fruits, yet cultivation is almost entirely neglected, and horticulture scarcely known. The Greeks have attempted to sow some of these waste lands, and have been repaid with most abundant crops; but unless the government take some more effectual measures for repressing the devastations and pillage of the Turks, and of securing to the agriculturists the produce of their industry, this good example will be but slowly imitated. On the banks of the channel,

* In a description of Constantinople, composed about a century after its foundation, there are enumerated, a capitol or school of learning, a circus, two theatres, eight public, and 153 private baths, 52 porticos, 5 granaries, 8 aqueducts or reservoirs of water, four spacious halls for the meeting of the senate or courts of justice, 14 churches, 14 palaces, and 4388 houses, which, for their size or beauty, deserved to be distinguished from the multitude of plebeian habitations. Gibbon's *Roman Empire,* vol. iii. p. 20.

† Dr Pouqueville, in his Travels in the Morea, &c. has given a list of the arts and trades carried on in Constantinople, with the nations by whom they are exercised. See p. 288.

Constantinople. however, are several elegant palaces with beautiful hanging gardens; and a few vineyards and kitchen plants are to be found in the environs of Pera. "Within a mile of the suburbs," says Mr Dallaway, "the gorgeous fanes of the capital rise as from a desert at the call of a magician; and the beautiful *chiftlik*, or country seat of Daoot Pasha, flourishing amidst a dreary waste, confirms the idea of his residence there." Washed on two sides by the sea, Constantinople enjoys a climate which may be considered as particularly healthy. It is never subject to such a degree of heat, as to be really deleterious, or to any severity of cold. Fogs are very rare, and the heavens are seldom obscured by clouds for any length of time. The average of the climate, in ordinary years, is estimated, by Dr Pouqueville, at 66 days of rain, 4 of snow, 6 of fog, 20 cloudy, 40 variable, 15 thunder, which leaves 214 almost uniformly serene. Thunder storms are not frequent, but very tremendous; and earthquakes are not uncommon. Whatever is unwholesome about this city, arises entirely from the indolence of the inhabitants, and the negligence of the government.

Harbour. Constantinople possesses one of the finest harbours in the world, both for security and convenience. It lies on the north of the city, which it separates from the suburbs of Galata and Pera, and is formed of an arm of the Bosphorus. From the seraglio point, to where it receives the waters of the river Lycus, it is about seven miles in length, and its breadth at the entrance is about 500 yards. It is capable of containing above 1200 ships; and, from the curve which it describes, and the rich cargoes which were continually wafted thither, it obtained, at a very remote period, the name of the Golden Horn, which it still retains. Owing to the vicissitudes of the tides being scarcely felt in those seas, and the steepness of the banks, ships of any burden can approach close to the shore, and unload their cargoes with very little trouble. The ships of war are generally moored on the city side of the harbour, while those of commerce are stationed at Galata. The whole of the canal is almost constantly filled with ships of different nations, who are obliged to stop here for a bill of health before they can enter the Black Sea, or for a passport to the straights of the Dardanelles.

Commerce. Upon entering the harbour of Constantinople, and beholding for the first time the immense quantity and variety of shipping, the bustle that appears on the quays, and the numerous boats that continually cover the water, a stranger would be led to rank this city among the most opulent and flourishing in Europe. "The ships, however, which crowd its port," says Dr Clarke, "have no connection with its welfare: they are for the most part French, Venetian, Ragusan, Sclavonian, and Grecian vessels, to or from the Mediterranean, exchanging the produce of their own countries for the rich harvests of Poland; the salt, honey, and butter of the Ukraine; the hides, tallow, hemp, furs, and metals, of Russia and Siberia; the whole of which exchange is transacted in other parts, without any interference on the part of Turkey." The commerce of this city is consequently very inconsiderable, compared with its extent and population; and its inhabitants seem incapable of appreciating the advantages of their situation. Under a wise government, they might obtain the riches of all the empires of the earth; but in their present state, they can scarcely obtain sufficient for their daily consumption.

Imports. From England they receive lead, tin, watches, all sorts of clock-work, hard-ware, woollen cloths of different qualities, spices, and glass-ware; but as they have no manufactures to give in return, the ships of that country are obliged to take in their lading at Smyrna. The Russians supply them with skins for pelisses, &c. cloths, and other manufactures, and take in return dressed leather, oranges, lemon-juice, and some dried fruits. They receive from France woollen cloths, wrought silks, caps, paper, sugar, cochineal, indigo, gold lace, and an infinite quantity of trinkets, and other trifles, for which they give grain of all kinds, coffee, goat's hair, cotton, wool, silk, &c. The Venetians carry thither a small quantity of gold stuffs, and a species of damask called Damasquetti, of which they make a considerable sale; also sweetmeats, glass, paper, drugs, wax candles, &c.; and receive in return leather, wool, cotton, wax, ashes of Cyprus, oil of Candia, coffee, and Cyprus wines. The following are their principal articles of importation, with an average calculation of their annual consumption and price.

Articles.	Quantity.	Price.
Tin, ...	400 barrels, .	160 to 170 piastres per kintal.
Tin plates, .	300 boxes, . .	155 to 250 do. the pair of boxes.
Shalloons, .	200 bales, . .	55 to 100 do. per piece.
Cotton yarn,	300 bales, . .	about £100,000.
Indigo, . .	350 seroons, .	34 to 46 piastres per oke.
Cochineal, .	60 barrels, .	65 to 100 do. per oke.
Dye-woods,	500 kintals, .	25 to 35 do. per kintal.
Pepper, . .	500 kintals, .	$2\frac{1}{2}$ to 3 do. per oke.
Vitriol, . . .	160 bottles, . .	5 do. per oke.
Rum, . . .	100 puncheons,	5 to 7 do. per gallon.
Loaf-sugar,	150 hhds. . . .	150 to 170 do. per kintal.
Raw and powdered do.	600 hhds. . . .	100 to 140 do. per kintal.
Watches, . .	15,000	
Rabbit skins,	20,000	2 do. each.

Cloth, 40 bales of British, the rest French and German.

Muslins. Those from India and Germany are preferred.

Printed cottons and Indian ginghams are much used.

Jewellery to a great amount, also arms and cutlery, but of British manufacture only about £5000 worth.

Glass and furniture in considerable quanties.

Exports. The exports of Constantinople are very inconsiderable; and of those articles which formerly constituted this branch of trade, they have now scarcely a sufficiency to supply their own wants. Indeed the Turks have no merchandise to give which are nearly equal to the value of their imports, and consequently the return is made almost entirely in gold, money, and diamonds.

The principal manufacture of Constantinople is a kind of silk stuff, wefted with cotton twist, and brocaded with gold and silver flowers. It is generally made by Armenians, and is much used by the Turks for vests and under garments. In the city and its environs, it is computed that there are about ten thousand looms employed in the manufacture of this and other inferior articles.

Conflagrations. This city has frequently suffered from conflagrations, and its inhabitants have often been thinned by the more dreadful ravages of the plague. When a fire is once raised, it spreads with such rapidity, that whole streets

Constantinople.

are sometimes consumed before it can be extinguished. On its first appearance, the alarm is given by beating a great drum from two high towers; and the night-watch immediately patrole the streets, crying in a lamentable tone, *Yan-gun war!* "Fire, fire." The sultan is then summoned, and, when the conflagration has lasted an hour, is obliged to attend in person, and to distribute money among the firemen, who are very inactive until he arrives. The general method of stopping the flames is by pulling down the adjoining houses. But sometimes so rapid is the progress of the flames, that whole streets are in a blaze at once; and on such occasions numbers of the unfortunate inhabitants perish. Such is the constant apprehension of danger in which they live, that no one thinks of going to bed without some kind of outer garment; and the women commonly sleep with all their trinkets of value about them. It is also the custom of every family to keep their most precious effects in a little box, which is set upon the table every evening, that, in case of alarm, it may be hastily carried off; and when at any time the whole family goes out, it is always carried with them. In 1633, 70,000 houses were reduced to ashes; and in 1788 the conflagration was so extensive as to threaten the universal destruction of the city. The houses, however, are speedily rebuilt, and in the space of a month, scarcely any appearance of the calamity is left. It is believed that these conflagrations have been more frequently occasioned by intention than accident; and it is no uncommon circumstance for the Janissaries, when displeased with the Grand Vizier, to set fire to different parts of the city, and to repeat it until the minister is removed.

Plague.

The plague sometimes desolates Constantinople for years together; and from 1783 to 1785, it is said to have swept away about 100,000 children and young people. It is, however, very difficult to calculate the number that die of this disorder, for their want is scarcely perceived, there being such a constant influx of people from the country to the capital.

Police.

The police of Constantinople is equal to that of any city in the world; and such a strict watch is kept in every part of the city, that scarcely a malefactor can escape detection. The city guard consists of a body of Janissaries, with their colonel, to every gate of the city and the most frequented streets; and each of the streets have besides a party of two or three men. A continual patrole parades the city day and night. One hour after sunset all the gates are shut, and entrance strictly prohibited; and as soon as the last Muezzin has called the hour of evening prayer, every sober Mussulman retires to his home, and the streets become like a desert.

Population.

The population of Constantinople has been variously stated. Habesci makes it a million and a half, while Eton reduces it to less than 300,000! Dallaway calculates it at about 400,000, which is the most probable computation; and tells us, that according to the register of the Stamboul effendissy, or mayor of Constantinople, in the end of the last century, there were 88,185 houses, and 130 public baths. Of its inhabitants, scarcely one half are Turks, the rest are Greeks, Jews, Armenians and Franks. East Longitude of St Sophia's Church 28° 55′ 15″, North Lat. 41° 1′ 27″. See Dallaway's *Ancient and Modern Constantinople*, passim; Macgill's *Travels in Turkey*, &c. vol. i. p. 249; Habesci's *Ottoman Empire*, p. 354; Eton's *Survey of the Turkish Empire*, p. 281; Gibbon's *Roman Empire*, vol. iii. p. 1, &c.; Olivier's *Travels*, vol. i. p. 13, &c.; Clarke's *Travels*, part i. p. 688, and part ii. p. 1, &c.; Neibuhr's *Travels*, vol. i. p. 8; and Pouqueville's *Travels in the Ottoman Empire*, p. 240, &c. CONTINUITY, LAW OF, is the name given by Leibnitz to a law, in virtue of which every thing that is done in nature is effected by infinitely small degrees. He maintains that *Natura non operatur per saltum,* and therefore that nothing can pass from one state to another, without passing through all the intermediate degrees. This law was slightly noticed by Galileo, but Leibnitz had the merit of adopting it as a leading principle in his philosophy. The argument by which he establishes the law of continuity appears to be conclusive. If a moving body receives an increment to its motion without the lapse of time, then the same body at the same instant is in two different states, which is absurd; and if the body receives the increment at the commencement of its motion, then the body must at the same instant be both at rest and in motion.

It is obvious, that when a ball is discharged from a cannon with a velocity of 1800 feet per second, it cannot be supposed to have acquired this velocity without the lapse of time. The ball must have had every assignable velocity from 0 to 1800 feet per second. In like manner, when a moving body changes its direction, it cannot move in the new direction without describing a portion of a curve, and moving in every possible direction between the one direction and the other. (*o*)

CONTRACT, in Law, is a voluntary agreement between two or more persons, whereby something is to be paid or performed by one of the contracting parties, for a valuable consideration to be given by the other. Contracts, from their nature, imply consent; and, therefore, those whom the law holds to be incapable of consent, as pupils, idiots, &c. cannot become parties to a contract.

The doctrine of contracts must necessarily occupy a considerable portion of the legal code of every civilized country; but the limits which our plan prescribes, will only permit us to exhibit a very short view of the several species of contracts, and to glance at the rules of law which are applicable to them.

By the Roman law, which, so far as regards this branch of jurisprudence, forms the basis of all modern systems, contracts were divided, according to the different modes in which they might be perfected, into *real, verbal, written,* and *consensual.* Real contracts were such as required that something should be actually paid or performed by one of the parties, before an obligation could be constituted against the other. Of this description were the four contracts of *loan, commodate, depositation,* and *pledge;* for the peculiar properties and effects of which we must refer to the civilians. See also the articles LOAN, HYPOTHEC, PAWN, and PLEDGE. The verbal contracts of the Romans, so far as they could be made effectual by action, were such as required to be perfected by certain *verba solennia,* or words of style. All other verbal agreements, in which this precise form was neglected, were considered as *nuda pacta,* on which no action lay. The written contract of the Romans, or *literarum obligatio,* as its designation implies, required the intervention of writing; in which the granter acknowledged the receipt of a sum of money, and bound himself to repay it to the creditor. Consensual contracts, according to the Roman law, were such as might be perfected by consent alone. Of this species were the contracts of SALE, LOCATION, SOCIETY, and MANDATE; for an account of which the reader is referred to those articles.

The writers on the law of Scotland have adopted the Roman division of contracts into *real*, *consensual*, and *written;* but, in the law of Scotland, there is nothing analogous to the *verborum obligatio* of the civilians; and therefore, as Mr Erskine observes, (*Inst.* b. iii. t. 2. § 1.) we may, without impropriety, apply the appellation of *verbal* to all such obligations, not requiring writing, as have no special name to distinguish them; and, contrary to the doctrine of the civil law, all such obligations will be effectual, provided no exception is made by positive institution. By the law of Scotland, writing is essential to all obligations or contracts relative to heritable rights, which are utterly ineffectual when merely verbal: (See DEED.) In Scotland also, there are certain contracts which require to be perfected in a peculiar form, and which will fall to be explained under their respective titles. See FEU *Contract*, MARRIAGE *Contract*, and COPARTNERY.

Contracts, according to the writers on the law of England, are either *express* or *implied.* Of the former description, are *debts*, *covenants*, and *promises.* Of the latter species, which in some degree resemble the *quasi contracts* of the Romans, are such as the law presumes that every man has contracted to perform. Among these may be reckoned, 1. The presumed contract or obligation, which every person is supposed to have come under, to pay such sums of money as are charged on him by the sentence of the law; and 2. All presumptive undertakings, which have been already explained under their proper title. See ASSUMPSIT. (*z*)

CONVERGENCY OF MERIDIANS. See EARTH, and SURVEYING.

CONVEYANCE, in Law, is a deed or writing, by which property is conveyed, or transferred, from one person to another. See DEED.

Conveyances, according to the law of England, are either *original*, as FEOFFMENT, GIFT, GRANT, LEASE, EXCHANGE, and PARTITION; or *derivative*, as RELEASE, CONFIRMATION, ASSIGNMENT, and DEFEAZANCE. By the former, the benefit or estate is created; by the latter it is enlarged, restrained, transferred, or extinguished. (*z*)

CONVEYANCING, is the art of framing legal deeds or conveyances. This is an art, which necessarily presupposes a considerable progress in civilization; for as, in the rude state of society, possession can be the only certain evidence of property, so, previous to the use of writing, must its transmission be accompanied either with actual delivery, or with certain symbolical forms or ceremonies, indicating the surrender of the subject from the one party to the other. Among the Jews, we find the evidence of a purchase thus defined in the book of Ruth, (Ch. 4, v. 7.) "Now this was the manner in former time in Israel, concerning redeeming, and concerning changing, for to confirm all things; a man plucked off his shoe, and gave it to his neighbour, and this was a testimony in Israel." Among the ancient Goths and Swedes, contracts for the sale of lands were made in the presence of witnesses, who extended the cloak of the buyer, while the seller cast a clod of the land into it, as a symbol of the transference of possession; and a staff or wand was also delivered from the vender to the buyer, which passed through the hands of the witnesses. Among the Saxons, the delivery of a turf was a necessary solemnity, to render effectual the conveyance of lands. In England, to this day, the conveyance of copyhold estates is usually made from the seller to the lord, or his steward, by delivery of a rod or verge, and then from the lord to the purchaser, by re-delivery of the same in the presence of tenants. Many traces, indeed, of these symbolical forms of conveying property survived the introduction of written conveyances, and are still to be found among the legal customs of modern nations. But as the evidence of the mere delivery of possession, whether actual or symbolical, depended on the ocular testimony and remembrance of the witnesses, the conveyance must have been extremely liable to be forgotten or misrepresented, and must often, indeed, have become totally incapable of proof. Besides, in the progress of civilization and commerce, the new wants and necessities of men required means to be devised of charging and encumbering estates, without having recourse to an absolute sale or transference of the property; and similar devices were sometimes found convenient and useful, in order to enable a proprietor to make suitable provisions for the numerous branches of a family. These growing wants and necessities gradually gave rise to the various forms of written deeds and conveyances. Most of these forms sprung out of the Roman jurisprudence, and were thence transmitted to the ecclesiastical notaries; who, during the dark ages of Europe, which succeeded the fall of the Roman empire, were the sole depositaries of that species of learning. When a new dawn of civilization began to spread over the European horizon, and the rapid advancement of society and commerce multiplied the transactions of civil life, writing was again introduced into business; many of the ancient institutions were revived; and the legal language, and forms of the Romans, were drawn forth from the recesses of the church, and applied to the existing state of policy and manners. The feudal system, too, by diversifying the modes of conveying and of holding landed property, and introducing more intricate relations between proprietors and tenants, made the use of written documents an indispensable requisite; and the transmission of property has thus become infinitely more capable of evidence, and its possession consequently more secure.

If we consider the objects which the art of conveyancing has in view; the important relations of society which must depend upon the degrees of perfection to which it has been brought; and the intricate questions which we see every day arise, with regard to the validity, import, and construction of deeds; the study of this art will undoubtedly appear to be a matter of no little consequence. There are two objects of importance, to which the attention of the conveyancer ought to be especially directed; 1st, The form of the writing, which, in every species of deed, is fixed by practice, in so far as regards all the general or secondary clauses. 2d, The technical language in which those clauses are to be framed, which are intended to express the particular purposes for which the deed is granted. With a view to this object, it is of the most essential importance to the conveyancer, to have a clear, intimate, and precise knowledge of the meaning attached by the courts of law to particular terms, in order that he may be enabled, distinctly and effectually, to express the intention of the granter. The forms of legal deeds will come to be discussed in a future article. (z)

CONVOCATION, a representative assembly of the clergy of the English establishment, summoned to meet at the same time with parliament. It is called by a special writ from the king addressed to the archbishops, and requiring them to summon together all the bishops, deans, and archdeacons, with a certain number of proctors, or proxies, for the chapters and parochial clergy in their particular provinces. In that of York, there is only one house, but on account of the small number of dioceses under its archbishopric, each archdeaconry elects two representatives. The convocation of Canterbury, like the parliament, is divided into two houses, the upper and the lower; the former consisting of the bishops, with the archbishop as their president; and the lower, of 22 deans, 53 archdeacons, 24 prebendaries or proctors of chapters, 44 proctors for the diocesan clergy, and 1 precentor, viz. the precentor of the church of St David's, which has no dean. Each convocation has a prolocutor chosen by themselves, whose duty it is to secure the attendance of the members, to collect their votes, and, in the case of the lower house, to report their resolutions to the upper house. The archbishop prorogues and dissolves it by mandate from the king; and during its sittings, the members in attendance have the same privilege of freedom from arrest with members of parliament when on duty.

Till the reign of Henry VI., the inferior clergy appear to have regularly sat by representation in parliament; and previous to the Reformation, both houses frequently met in convocation, merely by authority of the archbishop's summons, without any writ from the king. At that time, they not only possessed but exercised the power of making ecclesiastical canons, which, so late as the 21st year of Henry VIII. were declared by parliament to be binding on the whole realm, when they related to matters within the jurisdiction of the church. Though, as ecclesiastics, they were exempted from regular taxation, yet they were in the custom of granting, from time to time, subsidies to government, under the name of *benevolences*, and, to enforce the collection of these, the censures of the church were employed when necessary. This right they continued to exercise till the time of Edward I. who inserted a new clause in the writs which were usually addresed to the archbishops, (denominated, from the first word, the *præmuniens* clause,) by which the members of convocation were required to be present with the king in parliament, for the purpose of consenting to the imposition of taxes, and all other matters that should come before them. Even after this, however, they enjoyed the right of taxing themselves, though, from the reign of Henry VIII. the subsidies which they voted were, in general, confirmed by act of parliament, in order to become effectual.

But having incurred the high displeasure of this monarch, and afraid of the dangerous consequences with which resistance to his measures or will might be attended, they in 1530 agreed to the celebrated *Act of Submission,* which two years afterwards was passed into a law, by which they renounced for ever all right to meet in convocation without the king's writ, or to enact, publish, or execute any new canons without his special assent and sanction,—a law to which they have ever since paid the most implicit subjection. Whether from having found the plan of taxing themselves attended with greater difficulty and trouble than they thought compensated by the mere possession of the right to do so, or from some other more powerful ecclesiastical or political reason, they also, in 1667, consented silently to wave their exercise of this privilege, and to allow themselves to be included in the money bills passed by the House of Commons. In the act by which this arrangement was legally established, there is a clause which still reserves their right; but since that period they have never attempted to revive it, and the only compensation for this which they received and enjoy, is the liberty of voting as electors for members of parliament.

From the time that this alteration of its prerogatives took place, the convocation has seldom met. At the close of the 17th century, indeed, a violent controversy was agitated, chiefly by Dr Atterbury on the one side, and Doctor afterwards Archbishop Wake on the other, concerning the rights and privileges of the convocation; but the unfairness and heat with which it was conducted on the part especially of the former, had no tendency to convince the public, that the resuscitation of the jurisdiction and energies of such an assembly would be in the least degree expedient; and the proceedings which subsequently took place in it, in the case of Dr Clarke in 1714, and at the commencement of the Bangorian controversy in 1717, were by no means calculated to induce ministry to wish that it should statedly meet for business. Accordingly, though it has been regularly called at the beginning of every new parliament, it has not since that time been permitted to enter on any business or discussion, but is generally prorogued from time to time, till it is dissolved along with the parliament. See Collier's *Ecclesiast. Hist.* Hody's *History of English Convocations*, Fuller's *Church History*, and Tindal's *Continuation of Rapin.* (d)

CONVOLVULUS, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, page 137, 173.

CONYZA, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY, page 298.

COOK, JAMES, whose talents and success as a circumnavigator and discoverer have been seldom equalled, but never surpassed, was born in the year 1728, at Marton, a small village in the North Riding of Yorkshire. His parents were in a very humble line of life, but of laudable and distinguished honesty and industry: his father was a day-labourer to a farmer in the neighbourhood, and resided in a small cottage, the walls of which were chiefly mud. Till the age of thirteen, the subject of this article was principally employed in assisting his father in various kinds of agricultural labour suited to his years, while, at his leisure hours, he was instructed by a school-master in a neighbouring village, in reading, writing, and a little arithmetic. At seventeen he was put apprentice to a shop-keeper at a populous fishing town, about ten miles from Whitby. This circumstance seems to have decided his future line of life: the sight and neighbourhood of the sea drew off his thoughts from the business for which he was designed, and planted in his breast a strong propensity to become a sailor. His master, who observed this, and who discovered in him more solidity of character, and steadiness of application, than are generally found at so early a period of life, agreed to discharge him from his indentures; and he soon after bound himself, for the term of three years, to Mr Walker of Whitby, who had several ships in the coal trade. During this period he served with great diligence, and much to the satisfaction of his new master; and when it was expired, he continued on board one of his ships, first as a common sailor, and afterwards as a mate. Mr Walker appears to have formed a due estimate of his character and his talents, and to have contributed all in his power to confirm and expand them. In order that his knowledge might be extended beyond what a mere seaman could acquire, he was employed in rigging and fitting out one of Mr Walker's ships: on board of this ship he made two coal voyages, and afterwards, when she was taken into the service of government as a transport, he proceeded in her to Middleburgh, Dublin, Liverpool, and Deptford, where she was paid off. He seems to have continued in the coal trade till the year 1753, when Mr Walker offered him the command of one of his vessels: this, however, he declined, and entered on board the Eagle frigate, "having a mind," as he expressed it, "to try his fortune that way."

No school of practical navigation is equal to that which the coal trade supplies, for drawing out, or forming, those qualities which characterise a good seaman; and it has generally been supposed that Captain Cook, in this school, learned those habits of composed and steady attention, of cool resolution, undaunted firmness, and unwearied perseverance, which distinguished him through life, and which were brought into exercise with so much advantage to himself, to his country, and to the cause of science, in his voyages round the world.

He had not been long on board the Eagle before he obtained from Mr Walker a letter of recommendation to the captain, which was of considerable service to him, and which he always spoke of with sentiments of gratitude. In 1759, in consequence of his character as an active and intelligent seaman, he obtained a warrant for the post of master; and soon afterwards sailed in the Mercury to assist in the reduction of Quebec. While he continued on this station, his abilities recommended him to the execution of a piece of service, which not only required considerable skill, but exposed him to no small danger: It was necessary, in carrying into effect the plan of the attack against Quebec, to take the soundings of the channel of the river St Lawrence, between the Isle of Orleans and the north shore, opposite the French encampment: this could be done only at night; but notwithstanding this circumstance, and the risk to which he was exposed, both from the French and the Indians, (by the latter of whom he was nearly taken,) he completed the undertaking in such a manner, that he was soon afterwards employed on one of a similar nature, but on a much larger scale. This was a chart of the river St Lawrence below Quebec, which he made with such minute and scrupulous accuracy, that no other survey has been found necessary. The distinguishing feature in Captain Cook's talents has generally been thought to be solidity rather than quickness; yet there is good reason to believe, that before this time he had never used a pencil in drawing: but difficulties may be overcome, as well by persevering solidity, as by rapidity of intellect; in the same manner as an opposing obstacle may be removed, either by the weight or celerity of the body employed for that purpose.

After the reduction of Quebec, Mr Cook was appointed master of the Northumberland, in which ship he continued at Halifax during the winter. As he had now a good deal of leisure, he employed it in obtaining a knowledge of those branches connected with his profession, which hitherto he had had no means of studying: Euclid and astronomy more particularly occupied his time. In 1762, the Northumberland was employed in the recapture of Newfoundland; and as soon as this was accomplished, Mr Cook surveyed the harbour and heights of Placentius with so much zeal, perseverance, and ability, as to attract the notice, and afterwards secure the esteem and friendship, of Captain Graves, the governor of Newfoundland. Towards the end of this year, Mr Cook returned to England, where he married an amiable woman, with whom that portion of his subsequent life, which was not devoted to the service of his country, was spent in a most affectionate and happy manner.

When the peace of Paris had secured Newfoundland to Great Britain, Captain Graves pointed out to government the value of that island, and the advantage which would result from making an accurate and complete survey of its coasts; after some demur, they sent out Captain Graves for this purpose, and he, knowing the abilities of Mr Cook, made proposals to him to go out along with him, to assist him in the execution of his plan. Accordingly he was first employed in the survey of the islands of St Pierre and Miquelon, which he finished in a month, and then returned to England: he soon, however, was induced to resume his situation and employment. Sir Hugh Palliser, (who became acquainted with him while he was on board the Eagle, and who ever afterwards patronized him,) was appointed governor of Labrador and Newfoundland; and Mr Cook accompanied him in the same capacity which he had held under Captain Graves: but he now appeared in an official and public character, being appointed marine surveyor of Newfoundland and Labrador; and in order that he might execute the duties of his office in the most complete and satisfactory manner, a schooner was placed under his direction. The aptitude and tendency of his mind to explore whatever was unknown in geography, induced him to go beyond the mere line of his duty; for he not only published charts of the coast of Newfoundland, which, like every thing else that he undertook, possessed all that accuracy which skill and experience, united to a conscientious discharge of whatever he was employed upon, could give them; but he also explored the interior parts of the island, and gained a more complete knowledge of them than had ever been acquired before. While he was in this situation, he had an opportunity of observing an eclipse of the sun, a short account of which he drew up and sent to the Royal Society. He continued marine surveyor of Newfoundland, (occasionally returning to England) till the year 1767, when he resigned the office, and took up his abode with his family.

Great Britain may deservedly boast of being the first country which undertook voyages of discovery for the purpose of enlarging the boundaries of human knowledge. The discoveries of the Spaniards and Portuguese, in the 15th century, were prompted and performed solely for the sake of commercial advantages; and the same motive and object gave rise to the discoveries of the English and Dutch at that era, and during the 16th century. Afterwards war united with commercial avarice in these undertakings, and when there remained no country undiscovered, from which wealth could be acquired, or by the conquest of which power could be extended, or ambition gratified, the spirit of discovery languished. Towards the close of the reign of Geo. II. it again revived, but it was of a superior and more honourable character: Those who planned the voyages of discovery sought not only to benefit enlightened and civilized society, by extending the boundaries of science and enlarging the knowledge of human nature, but also to improve the condition of savage life.

Soon after peace was restored in 1763, Captains Byron, Wallis, and Carteret, were sent out on a voyage round the world; and before the two latter had returned, it was resolved that another voyage of the same description should be undertaken. The principal and immediate object of this proposed voyage was the observation of a transit of Venus over the Sun's disk, which would happen in 1769; and as this transit would be seen to the greatest advantage in some part of the South Sea, thither the vessel employed was to proceed. At first, Alexander Dalrymple, Esq. a gentleman well known for his geographical and astronomical knowledge, which he had directed with great zeal, industry, and perseverance, to the elucidation of the various voyages which had been performed for the purpose of discovery in the Southern Ocean, was fixed upon to conduct the undertaking; but some obstacles arising from his insisting upon having the command of a king's ship to be appointed for the service, Mr Cook was recommended by Mr Stephens, the Secretary to the Admiralty, and by his tried friend Sir Hugh Palliser.

In consequence of the high character which they gave him, he was appointed to the command of the expedition, and promoted to the rank of a lieutenant in the royal navy. The choice of a proper vessel being left entirely to him, he fixed upon the Endeavour, of 370 tons, which had been formerly employed in the coal trade. Every precaution was taken, and every preparation made, which could most effectually and completely secure the accomplishment of the objects for which this voyage was planned. A sufficient number of seamen were appointed to the Endeavour; 10 carriage and 12 swivel guns were put on board her, together with an ample store of ammunition and other necessaries, and provisions for 18 months. Having thus fitted out the ship in the most proper manner for the purposes of a long voyage, the next object was to obtain the company and co-operation of such scientific men, as would reap from it every species of benefit to human knowledge, which it might be capable of affording. Mr Green, an assistant at the observatory of Greenwich, was associated with Captain Cook, to conduct the astronomical part of the voyage, and Mr (now Sir Joseph) Banks, together with Dr Solander, an eminent Swedish naturalist, offered their services for the extension of natural knowledge. The object of the intended voyage was not confined to the observation of the transit of Venus; Captain Cook was also directed to examine the Pacific Ocean with accuracy, and to extend the discoveries in that part of the world.

In this article, it would be improper and irrelevant to enter upon a detailed account of the circumstances of this and the subsequent voyages of Captain Cook; while, at the same time, it would be equally improper to omit the notice of them altogether; we shall therefore offer a general sketch of his voyages, touching only on those points in which his merit as a navigator, and his character as a man, are the most decidedly and conspicuously marked.

On the 26th of August 1768, the Endeavour sailed from Plymouth; and, on the 13th of April 1769, she anchored in Matavai bay in Otaheite: this island had been discovered, or at least explored, by Captain Wallis, and on his return, (which took place immediately before Captain Cook sailed,) he pointed it out as a proper place for observing the transit of Venus. Captain Cook had well digested the plan he meant to pursue with respect to the regulation of the intercourse between his crew and the natives; and, in conformity to this plan, he drew up a set of regulations before he suffered any of them to land at Otaheite: in these regulations he displays not only humanity and good sense, but a thorough insight into the character and feelings of a British seaman. His coolness, firmness, and forbearance, were however soon put to the proof, notwithstanding the clearness and propriety of the regulations which he had communicated to the crew: on the one hand, the natives were greatly addicted to pilfering, and on the other hand, the seamen, when robbed by them, had recourse to the most harsh and brutal modes of punishment, not only disproportionate to the crime, but of such a nature as would stimulate to revenge, rather than prevent the repetition of the injury. Partly, however, by the strictness of his discipline, and partly by the authority and respect which his impartiality, and spirit of conciliation, united to an unbending determination not to suffer himself to be materially imposed upon, procured him from the natives, he succeeded in protecting his crew from plunder, and the inhabitants from inadequate or unprofitable punishment.

The observation of the transit of Venus having taken place on the third of June, and every information that was curious, or could be useful, having been collected respecting the island, the Endeavour left it on the 13th of July. As there were several small islands adjacent to Otaheite, Captain Cook ascertained their relative situation, and gave to the whole groupe the general name of the Society Islands. On the 6th of October, having directed his course to the southward, he fell in with New Zealand. As this had been generally considered and represented as part of a supposed southern continent, Captain Cook resolved to examine it so completely, as should leave no doubt on this head. After much difficulty and labour, and no small degree of risque, he ascertained it to consist of two islands, separated from each other by a narrow strait. The inhabitants were in the lowest state of ignorance and barbarism, and he had not been long among them before it was proved, beyond a doubt, that they were real cannibals. The difficulty of preserving peace between the seamen and them, was still greater than Captain Cook had experienced at Otaheite; and it is not unreasonable to suppose, (a supposition which candour will readily admit,) that the strong and precipitate measures of violence towards the inhabitants of New Zealand, and which he found it absolutely necessary to employ, gained such an ascendency over the milder and more forbearing habits which he had displayed at Otaheite, as to keep them under, on subsequent occasions, when they would have been amply sufficient to have checked or conciliated the natives. On his departure from New Zealand, he steered to the west, and came in sight of New Holland on the 19th of April 1770. The eastern coast of this immense island was thoroughly explored, and it was a task which called for all the distinguishing qualities of Captain Cook's mind. On one occasion the Endeavour was exposed to great and imminent danger, in consequence of striking upon a hidden rock; the Captain and crew were surprised that she did not make much water, though even the shock itself must have damaged the vessel considerably; but their surprise was changed into pious gratitude, when, on their arrival at a port in New Holland, a piece of the broken rock was discovered sticking in the ship's bottom: to this circumstance alone they were indebted for their preservation. That part of the coast, which they explored, is particularly dangerous for the numerous shoals that lie off it; and to guard against these, to extricate the ship when she got entangled among them, required no common degree of nautical skill, and cool, steady, presence of mind. In the midst of these difficulties and dangers, Captain Cook not only participated in the labour and fatigues of his crew, but he also gave the impulse of his superior confidence and knowledge to those who were disposed to despair, or who were ignorant how to act. Hitherto the health of his ship's company had been good, owing principally to the care which Captain Cook took on this important point: he laid down plain and strict regulations with respect to cleanliness and ventilation, and he himself superintended and enforced adherence to these regulations. Whenever an opportunity occurred of procuring fresh meat or vegetables, they were always served out to the crew with the most scrupulous regard to impartiality; indeed he wisely, as well as humanely, gave the preference to the seamen, when the supply was inadequate, since their habits and mode of life exposed them more to diseases, and on their exertions principally depended the safety of the ship, and the accomplishment of the objects of the voyage.

The Endeavour left the coast of New Holland on the 23d of August. Captain Cook intended to have directed his course north west, till he had made the south coast of New Guinea, but in consequence of a shoal he met with, a few days after he left New Holland, on which the vessel was nearly lost, he altered his course. On the 3d of September New Guinea was in sight: a singular and unaccountable circumstance occurred here. As Captain Cook, in his boat, was observing the natives on the shore, they swung round them short pieces of stick, from which there immediately issued fire and smoke, exactly resembling those of a musket, and of as short a duration, but no report was heard. Captain Cook did not stay long off the coast of New Guinea, but during his stay, he established the fact beyond all controversy, that it is a distinct country from New Holland.

During his voyage from New Zealand to Batavia, Captain Cook had an opportunity of rectifying the errors of former navigators. In the latitude of 7° 6′ S. and the longitude 225° W. he discovered two islands, which either had no place in former charts, or if they were laid down in them, under the name of the Arrow islands, are placed at too great a distance from New Guinea. On the 7th of September, the Endeavour was in lat. 9° 30′ south, and in long. 229° 4′, where the Weasal isles are laid down in the older charts; but as no land was discovered, Captain Cook considered that this position of them was erroneous, though he was not able to ascertain it. Even when our navigator arrived at places which had been not only explored, but colonized by Europeans, one of his principal objects was to ascertain their latitude and longitude, and to compare the result of his own observations, with the existing charts, or the information he received from the inhabitants: in conformity with this rule, when he arrived at Savu, a Dutch settlement between Timor and Java, he compared the latitude and longitude which is given to it in the charts with his own observations: in many maps and charts, which he consulted, it was not laid down at all, and in none was it laid down accurately; he ascertained the middle of it to lie in the latitude of 10° 35′ south, and in the longitude of 237° 30′ west. We shall notice only one more proof of the minute and valuable accuracy of Captain Cook's investigation into every thing that could prove of service to navigation; as probably to this instance of it, we are indebted for the important settlement of Prince of Wales' island. This island had formerly been much frequented by the East India ships; but, on account of the supposed badness of its water, it was forsaken. Captain Cook remained at it 10 days, and ascertained that though the lower part of the brook, which supplies the water, is brackish, yet higher up its quality was excellent; he therefore strongly recommended this island as a staple place for the East India ships to touch at. At Batavia he lost many of his crew, and such was the fatal effect of that climate upon several others, that they died during his voyage from thence to England, where he arrived on the 12th of June 1771. The journals and papers of the captain and officers, and of Mr Banks, were put into the hands of Dr Hawksworth, who drew up an account of the voyage, more acceptable from its style, to the man of taste, than useful to the geographer, the seaman, or the natural historian, from the facts which it contains.

Although Captain Cook in this voyage had done away one of the arguments which had been brought forward for the existence of a southern continent, by having ascertained that New Holland, which had been supposed part of that continent, was in reality an island; yet many ingenious and well-informed men still adhered to this opinion; and the attention of the public was called, in a strong and peculiar manner, to the question, by Mr Dalrymple. Government, therefore, resolved to ascertain its existence, by sending out two vessels, for the express purpose of traversing every part of the Southern Ocean, where it could possibly lie. It was determined in this enterprize to send out two vessels, instead of a single one, as Captain Cook, in more instances than one, during his voyage, had been fearfully impressed with the danger to which the lives of himself and his crew, and consequently the object of the expedition, had been exposed, when every thing was committed to a single ship. Two vessels were accordingly purchased which had been built at Whitby, and which, like the Endeavour, were of that kind used in the coal trade; the larger, the command of which was given to Captain Cook, was named the Resolution; Captain Furneaux commanded the other, which was called the Adventure. No alteration was made in their mode of equipment, or in the nature of their stores or provisions, but such as the experience of Captain Cook suggested. That no opportunity of gaining information might be lost, Mr Hodges, a painter; Mr Reinhold Forster and his son, naturalists and philosophers; and Messrs Wales and Bayley, astronomers, were to accompany the expedition.

On the 13th of July 1772, the ships sailed from Plymouth; and before they reached the 51st degree of south latitude, they met with several ice islands. On the 17th of January 1773, they arrived in 67° 15′ south latitude, without having discovered any land. During this navigation, the crews suffered extremely from the intense cold; while, under this suffering, they were compelled to be constantly on the alert, and active, in order to avoid the danger from the ice with which they were encompassed. As in the track which they had pursued, Captain Cook had directed his course and examinations in such a manner, as to satisfy himself that no southern continent existed in this part of the ocean, Cook.

and as the winter was approaching, he directed his course northwards; soon after which, the ships parted by accident. On the 26th of March, the Resolution arrived in Dusky Bay, in New Zealand. As he had experience of the character of the natives, he took special care to guard against their pilfering disposition, and not to rouse their vindictive feelings; so that the intercourse of his crew with them was rendered uniformly friendly. Having thus removed all apprehension, both from his own mind and that of the natives, he not only explored the country, but enriched it with the productions of more fertile regions. From Dusky Bay, the Resolution proceeded to Queen Charlotte's Sound, where the Adventure had already arrived. Between the 7th of June and the 26th of November, the Society Isles, and the Isles of Magdeburg and Amsterdam, were visited, and New Zealand was still further explored. About the beginning of November the two ships were again separated, and did not rejoin during the remainder of the voyage. Soon after the separation, Captain Cook proceeded on a further search for the southern continent; but notwithstanding he varied his course, and traversed in every direction which he thought afforded the slightest chance of discovering land, and actually got as far south as the latitude of 71° 10′, he was unsuccessful. By this time the winter of 1774 had commenced in these regions; and the Resolution sailed for the Marquesas. After having ascertained the situation and relative bearings of these islands with great accuracy, Otaheite was visited for refreshments. But Captain Cook's activity and his impatience of ease, prompted him speedily to quit this island, and to go in search of some islands to the westward, which had been discovered by Quiras, and imperfectly described by Bougainville. The situation and extent of this archipelago were accurately and fully explored by our navigator, and to the whole groupe he gave the name of the New Hebrides. In proceeding from them to the south, in order to afford another chance for the discovery of a southern continent, he fell in with and examined a large island, to which he gave the Name of New Caledonia. Here great accessions were made to botanical knowledge, and a species of spruce pine was found, in great abundance, very proper for spars,—a discovery of great importance, as, excepting New Zealand, there was not an island in the South Pacific Ocean where a mast or yard could be procured. During their further progress to the south, Norfolk island was also discovered, on which there is now a flourishing English settlement. From this island the Resolution proceeded to New Zealand, where Captain Cook had the mortification to find, that the inhabitants had utterly neglected the gardens which he had formed there during his previous visit, and scarcely any of the animals that he had given them were now in existence.

On the 10th of November he left New Zealand, and having sailed till the 27th in different degrees of latitude, from 43° to 55° 48′ south, without discovering land, he steered due east for Terra del Fuego, which he reached on the 17th of December. Although this country offered nothing interesting, or that was likely to be useful to navigation, Captain Cook examined it thoroughly. Indeed, his conviction and idea of duty, as well as his natural disposition and acquired habits, would not permit him to leave any country unexplored. In the whole run across this ocean, in a higher southern latitude than had ever been attempted before, (except by the Adventure), though he was constantly upon the look out for every circumstance in the smallest degree material or interesting, he remarked, that he never had made a passage any where of such length, or even of a much shorter extent, in which so few things worthy of notice occurred.

After he had examined Terra del Fuego, he sailed round Cape Horn, and on the 17th January 1775, discovered a dreary and uninhabited island, to which he gave the name of Georgia. From it he proceeded as far as the 60th degree of south latitude, and in this course several small points of land were seen, none of which however bore the appearance of being parts of any extensive continent. Having thus most scrupulously and completely performed the object for which he was sent out, he directed his course homewards, steering to the south of the Cape of Good Hope, where land was said to have been discovered by the French. This, however, he searched for in vain; and after touching at the Cape, he pursued his voyage, and anchored at Spithead on the 30th of July 1775, having, in the space of three years and 18 days, sailed 20,000 leagues, mostly in an inhospitable climate, and unknown seas; and during the whole of this time he lost but four men, and only one of them by sickness.

Soon after his return, he was raised to the rank of post captain, and also appointed a captain in Greenwich Hospital. In the beginning of the year 1776, he was chosen a member of the Royal Society, on which occasion a paper of his was read, containing an account of the method which he had taken to preserve the health of the crew of the Resolution during her voyage round the world: for this paper the annual gold medal was unanimously adjudged him. Although this second voyage of Captain Cook is not so full of curious and interesting incidents as the first, and perhaps falls short of it in the importance of geographical and nautical discovery, yet in another point of view it was highly useful. Before this voyage, navigators, and even Captain Cook himself, were very ill-informed respecting the most easy and effectual mode of preserving the lives of seamen, where the changes of climate, frequent and rapid, the want of vegetables and fresh provisions, and the unavoidable confinement of a ship, add their destructive influence to the indolent and not very cleanly habits which distinguish this valuable class of men. Towards this object our navigator directed his most anxious and unremitted attention; and that he succeeded in accomplishing it, is sufficiently proved by the fact we have already noticed, that out of a crew of 118, only one died of sickness. In the paper which he submitted to the Royal Society, the means that he employed were clearly and fully detailed; they were simple, and depended for their efficacy as much upon the regularity and steadiness with which he enforced them, as upon their nature and quality. The character of the disorder, which generally attacks and carries off seamen during long voyages, sufficiently marks its cause: Before Captain Cook directed his thoughts to this important subject, a supply of fresh provisions and vegetables were regarded as the only means which could prevent or remove the attacks of the scurvy; but as, notwithstanding the use of these means, the deaths on long voyages were very numerous, Captain Cook took other measures. As this disorder proceeds from or produces debility, he was constantly attentive to protect his men from cold, wet, and over-fatigue: he also frequently aired and fumigated his ship; but, above all things, he particularly enjoined cleanliness and exercise. The merit of Captain Cook in these regulations, is sufficiently evident from this circumstance, that since they were known to be so completely efficacious in his voyages, and since they were so amply and clearly detailed in his paper, the mortality in the longest voyages is scarcely proportionally greater than it is on shore.

In consequence of the objections which had been made to Dr Hawksworth's edition of the first voyage, Captain Cook undertook the publication of the second; and the manner in which it is written is extremely proper for the subject, and therefore highly creditable to himself: The stile is that of his own character, simple, clear, and manly, looking more to what is useful than what is ornamental.

The existence of a southern continent being now banished from the belief of most people, at all capable of forming an opinion upon the subject, only one disputed point of nautical geography, of any magnitude or importance, remained to be settled; and that was the existence or practicability of a communication between the Atlantic and Pacific Oceans, by a high northern latitude. Could an easy and safe communication be discovered, it would greatly shorten the passage between the eastern and western continents; that it did exist, many eminent geographers were of opinion, and to this opinion they were led by the appearance of the coast on the east side of North America: the deep and extensive bays there seemed to promise a communication with the Pacific Ocean; and if the coast on the north-west of this continent were explored, they expressed their belief, that the desired object would be accomplished. The British government, therefore, resolved to explore both the eastern and western coasts; to the former, Lieutenant Pickersgill was sent out in 1776, and, in the subsequent year, Lieutenant Young. But the most important and arduous undertaking was, the examination of the western coast of America: of it very little was known. Government, when they had formed the plan of these new voyages of discovery, naturally looked to Captain Cook to undertake the principal part in them; but as he had already done so much for his country, and the extension of geographical and nautical knowledge, they hesitated about making a direct proposal to him on the subject. It was, however, only necessary to mention, apparently incidentally, the importance of the scheme in his presence: he immediately entered into it with the utmost zeal, and voluntarily offered to undertake the execution of it. The Resolution, and another vessel called the Discovery, were prepared for the voyage, with as little delay as possible. Captain Cook took the command of the first, and Captain Clarke of the other. The equipment was similar to that of the second voyage, except that the department of natural history was entrusted to Mr Anderson, the surgeon of the Resolution.

On the 12th of July 1776, the Resolution sailed from Plymouth; the Discovery, not being ready, did not sail till a short time afterwards. The two ships joined at the Cape, which they left about the end of November; and after having visited New Zealand and the Friendly Isles, with the productions and inhabitants of which they gained a more accurate and extensive acquaintance, and having discovered a numerous groupe of inhabited islands in north latitude 21°, to whom Captain Cook gave the name of the Sandwich Islands, they proceeded to the western coast of North America, which they reached on the 7th of March 1778. At Nootka Sound, in latitude 49° 33′ N. they repaired their ships, previously to entering upon the primary and most important object of their voyage. Thence, to the north, they examined the coast with great care: wherever there was the slightest appearance of an inlet or large river, Captain Cook either went himself, or sent such officers as he could trust, to explore it; and though many difficulties occurred, and there existed no chart or journal of a previous voyage to direct his examination, or rectify any mistake into which he might have fallen, yet only in one case does he appear to have formed an erroneous opinion. Captain Vancouver has since proved, that what Captain Cook supposed was a river, (and to which his own name was given,) is only an inlet of no great extent or importance. During this part of the voyage, the coasts of Asia, as well as those of America, were examined; and in the comparatively short space of time which was spent on this examination, Captain Cook obtained a more correct and full knowledge of them than the Russians had procured, notwithstanding they had many settlements here, and several vessels had been employed for the purpose of exploring the adjacent coasts. As the winter was approaching, he now resolved to direct his course to the south, after having examined the western coast of America from the latitude of 43° to 70° north, containing an extent of 3500 miles; "ascertained the proximity of the two great continents of Asia and America; passed the straits between them, and surveyed the coasts on each side to such a height of northern latitude, as to demonstrate the impracticability of a passage in that hemisphere, from the Atlantic into the Pacific Ocean, either by an eastern or a western course."

On the 26th of November, the Resolution and Discovery arrived at the Sandwich Islands, which Captain Cook surveyed with more care and accuracy, than his time would permit when he visited them before. In the course of this survey, Owhyhee was discovered, the largest and most important of the whole groupe. As it was now absolutely necessary to refit the ships, and prepare them for a return to a high northern latitude, his first object was to find out a proper bay for this purpose in Owhyhee; after due examination, a bay named Karakakooa was fixed upon. In the course of this visit to the Sandwich Islands, the character and talents of the natives particularly struck and interested Captain Cook; in the former, there was a greater degree of openness than he had witnessed among the inhabitants of the other islands which he had visited; they supplied his wants with great cheerfulness and liberality, while their merit was superior, in this respect, to that of other savages, as they seemed to possess more accurate ideas of property. With regard to their talents, they were naturally good, uniting a considerable degree of quickness, with more steadiness of application, than the inhabitants of Otaheite displayed. When Captain Cook visited them, they had already made no small advance in several of the arts of life; and they manifested an earnest and actuating desire to improve their useful knowledge, by the instructions and example of the British.

This cast of character and talents led them to receive and treat Captain Cook with great attention and respect; in their opinion he appeared to belong to a superior race of beings. Having completed the purposes of his visit, he left Owhyhee on the 4th of February 1779; but a few days afterwards, the Resolution having sprung her foremast, both the ships returned to Karakakooa. The disposition and conduct of the natives towards them were different from what it had been; there was less cordiality and frankness, and a stronger and more systematic tendency to pilfer. Captain Cook could not account for this change; it mortified him extremely to perceive himself under the necessity of guarding against, and punishing, the thefts of those, of whose character he had formed such an high opinion. He soon found, however, that the utmost strictness and severity were absolutely indispensible, if he wished the ships and crew to be preserved from utter plunder; every day the natives stole something, and even when they were detected and punished, their thefts became more insolent and daring; at last they seized upon, and carried off a large cutter belonging to the Resolution. The most decisive and strong measures were adopted by Captain Cook; he ordered two boats to intercept the canoes which should endeavour to leave the bay, and, if necessary, to fire upon them. On all similar occasions, one of his first objects was to seize the person of the king or chief. This plan he determined to follow now, and for that purpose he went on shore himself with an armed force. Notwithstanding the change in the disposition and behaviour of the natives, the reason they knew they had given for the anger of the English, and the suspicion and alarm which the armed men must have excited, they received him with their accustomed respect; but this was completely destroyed as soon as they perceived that their king was a prisoner. Every thing now bore the appearance of the most angry and determined hostility; a crowd gathered round Captain Cook, and made use of the most menacing gestures; as he persevered in detaining the king, and in carrying him on board the Resolution, others of the natives ran for their arms. In this critical situation, the men who were left in the boat fired upon and killed one of the chiefs; as soon as this was known, the crowd round Captain Cook increased in numbers and in violence, and such an implacable spirit was shewn, that he thought it prudent to liberate the king, and turn his whole thoughts to the safety of himself and his men. But it was now too late; many of the natives did not perceive that their king was liberated, and the anger and desire of revenge in those who did, was roused too high to be allayed by this measure, which they probably ascribed solely to fear and compulsion. Captain Cook pushed forward towards the shore, off which a boat was lying to protect him, and receive him on board; every minute his situation became more alarming; his progress was impeded by the crowd; stones were thrown—the marines fired—the savages rushed upon them, and nearly overwhelmed them. The strength of Captain Cook by this time was nearly exhausted by pushing through the crowd, and protecting himself from their attacks; he might, however, probably have escaped, had not the boat in waiting drawn farther off. Even in this crisis of personal peril, he was more anxious for the safety of his men than of himself; they all got on board, he alone remained on the shore; the blow of a club staggered him; he fell on one knee, and as he was rising, a stab was given him; he fell again into the water, and after struggling for some time with the savages, who held him down, he was dispatched by a blow with a club. As soon as he was dead, all were eager to plunge their daggers into his body; and after they had thus glutted their revenge, they carried it off in triumph. Captain Clarke, who succeeded to the command of the expedition, made every effort to recover the remains of Captain Cook; but only his bones were obtained, and these were committed to the deep amidst the heart-felt grief of all those who had served with him.

Captain Cook was above the common size; his countenance was expressive, but rather austere. His manners were plain, simple, and manly. His natural disposition, and the habits of his professional life, rather inclined him to be peremptory and hasty; but his good sense, his knowledge of mankind, and above all his humanity and benevolence, soon bore down this tendency. His talents were of the most useful kind; he saw clearly and deeply into whatever interested him; and his designs were accordingly bold and extensive. When these were formed, he expressed no doubt about their execution, for the same perspicuity and orderly arrangement of thought which enabled him to form the designs, also enabled him to devise the most simple and effectual mode of executing them. In the execution he was equally distinguished; no difficulty perplexed him, no danger appalled him; the talents and knowledge he possessed were always completely at his command, when they were most needed; and, for great designs, he was also qualified by the constitution of his body, which was robust, inured to labour, and capable of supporting the greatest fatigue and hardships. No food, however coarse, was ungrateful to his palate, or unacceptable to his stomach.

As a navigator, he was of the highest order, whether we contemplate the discoveries he made, or the means by which they were accomplished. That England did not partially overrate his merits, was abundantly and most unequivocally testified, by the honours which were bestowed upon his memory by foreign nations.

Captain Cook left a widow and three sons, upon whom pensions were settled. The sons were brought up in the service of their country; one of them was lost at sea, and the other two fell honourably in her cause. See Kippis' *Life of Cook*. (W. S.)

COOPER, ANTHONY ASHLEY, first earl of Shaftesbury, was one of the most prominent characters among the English politicians of the seventeenth century. He was born in 1621, in Dorsetshire. His father was a baronet; and young Anthony, being an only son, inherited, along with the title, a large landed property, said to amount to L. 8000 a-year; an extraordinary sum in these days. After receiving the rudiments of education at home, he was sent, at fifteen, to Oxford, and afterwards to Lincoln's Inn. His education seems to have been very well conducted, and his mind directed to serious study, at an age when inheritors of fortune cannot, in general, be withheld from a very different course. He was returned a member of parliament so early as 1640, when only in his nineteenth year. A few years afterwards, we find him taking part with the king in the civil war, and venturing, according to Mr Locke, to recommend to Charles to grant the commons a redress of their grievances, as the only effectual method of terminating the war. "I entreat your majesty," he said to the king at Oxford, "to empower me to treat with the parliament garrisons; to grant them an assurance that, arms being laid down on both sides, a general amnesty shall reinstate all things in the posture they were in before the war, and that a free parliament shall do what remains to be done for the settlement of the nation." The king, it is believed, authorised him to try the experiment in his own county; and he appears to have obtained possession of Weymouth, at that time a garrisoned town, on an understanding of the above nature. Prince Maurice, however, having troops in the neighbourhood, entered Weymouth, and permitted his soldiers to live at free quarters on the inhabitants. Sir Anthony remonstrated warmly against this infraction of his promise; but finding representations ineffectual, he broke off a pending negotiation with the towns of Poole and Dorchester, apprising them that he could not be responsible for the fulfilment of the promised conditions. The king, preferring the counsels of his old adherents to the propositions of so young a person as Sir Anthony, the latter was induced, as some say, by a consideration of safety, but more probably by offended pride, to change sides, and connect himself with parliament. His disposition rendering him ardent in whatever he espoused, he soon accepted a commission from parliament, and raised forces in Dorsetshire to combat the royal cause; but, notwithstanding his activity in the field, he is said to have been regarded by the Court among the least rancorous of their opponents.

Sir Anthony appears to have taken no part in the proceedings connected with the trial of Charles. When Cromwell began to throw off the mask, and to appropriate to himself the power of which he had stripped his sovereign, Shaftesbury had the courage to join a few spirited men in opposing his usurpation; although Cromwell sought to gain him, along with other persons of consequence, by appointing them members of his privy council. After the Protector's death, Sir Anthony was suspected to be in correspondence with the royalists. Appearances were strongly against him, but he had the address to obtain an acquittal of the charge. He next aimed at the same result by indirect means, engaging Monk to march southward with his army, and taking an active part in detaching Vice-admiral Lawson, who commanded the fleet, from the cause of the commonwealth. The Restoration being accomplished, Sir Anthony became a member of the privy council, and was raised to the peerage by the title of Baron Ashley. He is said to have owed his first appointments at court to the influence of the Earl of Southamptom, to whose family he was related by marriage. After being for some time chancellor of the exchequer, he became one of the lords commissioners of the treasury, and lord-lieutenant of the county of Dorset. In April 1672 he was created Earl of Shaftesbury, and, towards the end of the year, invested with the high post of chancellor of England. It is singular enough that Shaftesbury, doubtful as his character was in most respects, is allowed to have acquitted himself with equal honour and ability in the capacity of a judge. He laboured to abridge the delays of process as much as possible; and though he failed in persuading the lawyers to relinquish their circuitous forms, he succeeded, by his habits of attention and decision, in clearing a great part of the arrears of that court.

Of his proceedings in a political character, a very different opinion is entertained. Though he does not appear to have been privy to all the conditions of Charles' disgraceful treaty with France, he had a principal hand in giving effect to the Dutch war—to the projects relative to a change of religion—and to the exercise of a corrupt influence in the election of members of parliament. The shutting up the exchequer, the boldest, perhaps, of all the measures of this shameless reign, is now considered to have been less the act of Shaftesbury, than of his iniquitous coadjutor in office Clifford. At last, in 1673, the tide of popular opinion running very strongly against the French alliance, and Charles being disappointed in his dream of a golden harvest from Dutch captures, Shaftesbury determined not to remain so long with the court, as to lose the alternative of gaining favour with the people. Charles was hard pressed by parliament to cancel the obnoxious declaration of indulgence, in regard to liberty of conscience; a declaration which, from its partiality to Catholics and Protestant dissenters, had given great alarm to the church. Shaftesbury, and his brother members of the cabal, strongly dissuaded the king from complying; but Charles disregarded their arguments, and made, in parliament, a public renunciation of the act. Shaftesbury now saw that the king had secret views, and that a minister was unsafe in encountering public odium in his service. He therefore took his measures, not merely for withdrawing from court, but for assuming a lead in the opposition. The ostensible ground which he took, was that of resistance to the Duke of York's succession to the crown, and of alarm for the Protestant religion.

We are now arrived at the epoch in Shaftesbury's life, when he became definitively the opponent of the Court. As leader of the opposition, he discovered perhaps more talent and exertion than in any former situation. His usual residence was in London, towards the interior of the city, where his popularity became extremely great. The long parliament having re-assembled in February 1677, after a recess of fifteen months, Shaftesbury argued that it ought to be considered as dissolved. This opinion he asserted with so much warmth, that the court thought proper to commit him and three other peers to the Tower. His fellow prisoners were not slow in making their submission, and obtaining a discharge; but Shaftesbury at first took higher ground, and brought his case before the Court of King's Bench. Being, however, remanded to the Tower, and becoming anxious to resume his station in the ranks of opposition, he made a virtue of necessity, and, on declaring his submission, was restored to liberty. He now came forward as a powerful opponent of the Earl of Danby's administration. A change becoming indispensible, the king professed to adopt the advice of Sir William Temple, and to call to his privy council the most distinguished men in public life in the kingdom. When all was on the eve of being settled, and Sir William, with his friends, were making the definitive arrangements, the king inserted the name of Shaftesbury as lord president of the council, and made a jest of all Sir William's objections to this unexpected nomination. Had Sir William been of a suspicious disposition, he would have discovered, that this act of Charles was nothing more than a part of the dissimulation which he had carried on throughout the whole proceedings for the arrangement in question. Shaftesbury retained his station of lord president from April to October 1679; but finding that, without possessing influence over the measures of the court, he was in danger of ruining his popularity, he took the determination to withdraw from all official employment.

The year 1678 was the æra of that mysterious intrigue, the Popish plot. Shaftesbury having seized with avidity this favourable opportunity of shaking the power of the Duke of York, and having pursued the parties accused with unrelenting severity, has got credit for being the author of the whole conspiracy. Sir John Dalrymple goes so far as to allege, that papers which he had seen convinced him that Shaftesbury was the contriver of it, though the persons he made use of as informers ran beyond their instructions. Sir John adds a story of Shaftesbury, saying, when pressed in regard to the absurdity of the circumstances, "It is no matter; the more nonsensical the better: if we cannot bring them to swallow worse nonsense than that, we shall never do any good with them." It is to be regretted that Sir John's judgment in forming conclusions from public documents was far inferior to his industry in procuring them. Shaftesbury was not likely to use such words as these in company with a person capable of reporting them; and it is much more probable that he turned the circumstances of the plot to account, than that he was the inventor of it. His persevering activity on this occasion, his ardent support of the Exclusion Bill, and his subsequent protest against the return of the Duke of York from abroad, rendered the latter his implacable enemy.

Shaftesbury continued at the head of the opposition so long as there was a parliament. In 1681, Charles having come to the determination of finally dispensing with these troublesome assemblies, retrenched his expences, published an appeal to the people on the conduct of parliament, and renewed, in secret, his treaty with France. By this time the circumstances of the Popish plot began to be discredited, and the court ventured to proceed against the leading members of opposition. The aged Earl of Stafford was tried and brought to the block. Shaftesbury was apprehended, examined before the Privy Council, and committed to the Tower. Here he remained more than four months, and was brought to trial towards the end of the year. The witnesses brought forward against him were of bad character; but a paper found in his study, and containing the draught of an association, was made the subject of a very serious charge. As it was not however in his hand-writing, and contained nothing treasonable in regard to the person of the sovereign, the grand jury thought proper to discharge Shaftesbury. His Lordship, when released, assumed a bold tone, and brought an action against a person who, in conversation, had attributed to him traitorous designs. Such was Shaftesbury's popularity, in the metropolis, that the defendant resorted to the unusual expedient of moving for a trial out of Middlesex, on which the suit was dropped.

The fiction of the Popish plot was succeeded in 1682 by a real conspiracy, known by the name of the Rye-House Plot. Lord Russel, Lord Essex, Algernon Sidney, and other leaders of opposition, being debarred from the means of making a constitutional resistance in parliament, resorted to the equivocal course of secret combination. Though they disliked Shaftesbury's character, and still more the prospect of his assuming an ascendancy among them, they felt their need of his powerful and daring party in the city, and did not hesitate to make him completely privy to their schemes. Shaftesbury, taught by long experience, the expediency of prompt exertion when engaged in so hazardous a scheme as the overthrow of the executive power, was for losing no time in striking a blow. Michaelmas (1682) was first proposed as the time of insurrection, but it was delayed month after month. Shaftesbury, distrusting the judgment of the conspirators, and out of patience with their reiterated delays, thought it expedient to withdraw from the power of his enemies.

In November (1682) he crossed over to Holland, and took a house at Amsterdam. Here, however, his active career was soon brought to a close. The gout, to which he had long been subject, returned with redoubled violence, and attacking his stomach, put an end to his life in January 1683, in the 62d year of his age.

No character in the English history has been more the subject of controversy than that of Shaftesbury. Though the majority of writers are disposed to condemn him in very strong terms. The exculpatory efforts of Mr Locke, and the discovery of his innocence in two or three very suspicious transactions, have tended to abate, in some measure, the current of general odium. There are, it is understood, in the possession of the Shaftesbury family, various documents explanatory of his conduct, and calculated, it is said, to mitigate the severity of public censure. These documents have been confided, with a view to publication, to several persons, none of whom have discharged the task. Our limits do not permit us to enter on an analysis of the character of this extraordinary man, and we regret it the less, as a biographical account of him may, we understand, be ere long expected. The brightest part of his conduct was an exemption from the influence of avarice, a very prevalent vice among the ministers of that age. Hence his unimpeached integrity in the administration of justice. But how different must be our opinion of his political proceedings, whether we regard him as a member of that cabal which aimed at the overthrow of the constitution, or as the leader of a popular party, prosecuting the victims of a plot which he must have known to be fictitious. His temper was violent; his disposition restless; but, on the other hand, he was indefatigable in business, and impressive in public speaking. Unfortunately he did not scruple to set at work the worst passions of mankind for the promotion of his ambition, and his repeated changes from the court to the people, deprive his character of all claim to the influence of public principles. We conclude this article by transcribing one of the latest opinions expressed in regard to Shaftesbury. It is contained in a letter from Mr Fox to his friend, Sergeant Heywood, and forms the last document in the preface to the *History of the early part of the Reign of James II.*

"I am quite glad I have little to do with Shaftesbury; for as to making him a real patriot, or friend to our ideas of liberty, it is impossible, at least in my opinion. On the other hand, he is very far from being the devil he is described. Indeed, he seems to have been strictly a man of honour, if that praise can be given to one destitute of *public* virtue, and who did not consider Catholics as fellow-creatures; a feeling very common in those times. Locke was probably caught by his splendid qualities, his courage, his openness, his party zeal, his eloquence, his fair dealing with his friends, and his superiority to vulgar corruption. Locke's partiality might make him, on the other hand, blind to the indifference with which he (Shaftesbury) espoused either monarchical, arbitrary, or republican principles, as best suited his ambition; but could it make him blind to the relentless cruelty with which he persecuted the Papists in the affair of the Popish plot, merely, as it should seem, because it suited the purposes of the party with which he was then engaged? You know that some of the imputations against him are certainly false; the shutting up the Exchequer, for instance. But the two great blots of sitting on the Regicides, and his conduct in the Popish plot, can never be wiped off. The second Dutch war is a bad business, in which he engaged heartily, and in which (notwithstanding all his apologists say,) he would have persevered, if he had not found the king was cheating him." (χ)

COOPER, Anthony Ashley, grandson of the preceding, and third Earl of Shaftesbury, was born in 1671. Literature was the object of his pursuit, as political aggrandisement had been that of his grandfather. The latter, desirous to familiarise his descendant with the learned languages from his earliest years, placed him under the charge of a schoolmaster's daughter, accustomed to speak Greek and Latin with fluency. He was thus enabled to read passages of authors in either language at the early age of eleven. At fifteen he began his travels, and passed three years on the Continent. Returning to England, he had the good sense to decline accepting a seat in the House of Commons during five years, and made a scrupulous appropriation of his time to study. It is related that, soon after taking his seat, he rose to speak on a bill, brought in for the regulation of trials for high treason. It had been proposed to refuse counsel to prisoners in this predicament; a measure which Lord Ashley regarded as tyrannical, and was determined to oppose. He had carefully prepared his speech; but on standing up to deliver it, he was so awed by the presence of the assembly, as to feel himself unable to proceed. The house, however, encouraging him, he recollected himself so far as to give a very happy turn to his confusion. "If I, who rise only to give my opinion on the bill now depending, am so confounded, what must the condition of that man be, who, without any assistance, is pleading for his life?" The effect on the house of this well-timed appeal was very favourable, and Lord Ashley continued a zealous supporter of the cause of liberty. But his feeble health was unequal to the fatigue of regular attendance in parliament, and his inclination led him to prefer literary retirement. His father dying in 1699, the young lord gave his interest to the ministry, who were then engaged in supporting King William's plans for a new alliance against Louis XIV. It is said that King William declared, that Lord Shaftesbury's interest had turned the balance in favour of ministers, in the election of the new parliament; and it is added, that he made him an offer of the secretaryship of state.

On the demise of King William, the government passing into the hands of other ministers, Lord Shaftesbury forsook the court, and returned to his literary occupations. Holland being at that time the residence of Bayle, Le Clerc, and other free enquirers, his Lordship diversified his retirement by an occasional visit to that quarter. Some years afterwards, in 1708 and 1709, he began to publish. His first works were, a Letter on Enthusiasm; the Moralist; a Philosophical Rhapsody; and *Sensus Communis*, an essay on the freedom of wit and humour. At this time also he became a married man, less it appears from the influence of love or ambition, than to comply with the solicitation of those, who, to use his own words, "thought the family worth preserving." In 1710, appeared his well-known Soliloquy, or Advice to an Author, a work evidently superior to his preceding publications. But his health was now in such a state of decline, as to require a change of climate. Notwithstanding the war, he obtained leave to travel through France, and proceeded to Naples, where, after residing a year and a half, he died in 1713, at the early age of forty-two. The last part of his career was employed in finishing a corrected edition of his great work, the Characteristics. It came out soon after his death, and the prints first published with the work were invented by him, and designed under his personal inspection. Publications of parts of his correspondence took place in succeeding years; first in 1716, under the title of, Letters from a noble Lord to a young man at the University; and in 1721, under the title of, Letters from the late Earl of Shaftesbury to Lord Molesworth.

The advantage of an early familiarity with the ancient languages, was strongly exemplified in the course of his Lordship's studies. Though well acquainted with the eminent writers in his own language, his favourite occupation was the perusal of the authors of Greece and Rome. The moral works of Xenophon, Horace, and Epictetus, were so acceptable to him, that he made a rule to carry copies of them in his various excursions. These copies are still extant in the family library, and the number of his marginal notes bears ample testimony to his zeal and industry. Happy had it been if his Lordship had been content to build his fame on the extent of his classical attainments and knowledge of morals, without coveting distinction, by professing scepticism in regard to the Christian religion. We regret this the more, as Lord Shaftesbury's character, like Mr Hume's, was marked by many valuable qualities. "He was," says Warburton, "temperate, honest, and a lover of his country." His pretensions to great literary distinction, however, are more doubtful than his title to the praise of honour and patriotism. The high polish of his style, and the sentimental vein of his philosophy, procured him, for many years, a great reputation; but acute scholars, such as Dr Jortin and Mr Gray, did not hesitate to express a very different opinion. A later author, however, Lord Monboddo, extols Lord Shaftesbury to the skies, equally on the ground of composition and of philosophy. To enter into an elaborate disquisition of this subject would much exceed our limits; and we are spared the trouble, by being enabled to appeal to an opinion from a high quarter, which has probably engaged, long ago, the attention of most of our readers; we mean, Dr Blair's judgment of Shaftesbury, in the Lectures on Rhetoric and Belles Lettres. That eminent critic bestows much praise on the skilful and elegant construction of his Lordship's language, while he passes a merited censure on that stiffness and fastidiousness, which prevented him from expressing any thing with simplicity, and which led him into perpetual circumlocutions. His Lordship left one son, who became the fourth Earl of Shaftesbury. (χ)

COPAIFERA, a genus of plants of the class Decandria, and order Monogynia. See Botany, p. 219.

COPAL. See Chemistry, p. 123, and Varnish.

COPENHAGEN, originally *Kiobmandshavn*, "the merchant's harbour," the capital of Denmark, is situated on a small promontory on the eastern coast of the isle of Zealand, in North Lat. 55° 41′ 4″, and East Long. 12° 34′ 15″. It is fortified towards the land with regular ramparts and bastions, and environed with a wet ditch, which is both broad and deep. On the sea side its principal defence is the Crown battery, which is about half an English mile from the shore. It is built in the form of a square; the water flows into the middle of it; and, since the battle of Copenhagen, it has been greatly strengthened and enlarged. The citadel, which stands at the north-east extremity of the town, is but small, containing two battalions, and its only gate is fortified with five bastions.

Copenhagen, though of no great extent, is one of the handsomest cities in the north of Europe. It is between four and five miles in circumference, and consists of the old and new town, and Christianshafen. The streets are, in general, broad and well paved, with a foot path on each side, but sometimes very narrow and inconvenient; and some of them are intersected by canals, which afford a great facility to the transportation of goods. The Rue de Goths, and Amalien Gade, in particular, are beautiful streets, and the former is about three quarters of an English mile in length. There is a peculiarity in the mode of building in this city, which is mentioned by Mr M'Donald, and which is indeed a very judicious and convenient one in a crowded city. "Instead of the usual right angles," says he, "formed by the corners of the houses at the extremities or divisions of the streets, the builders of Copenhagen have squared them off in a semi-octangular form, and thereby secured various advantages. Carriages and horses cannot so frequently run foul of each other, or run down persons on foot at the turnings of the streets; the space gained gives a free circulation of air, and the look of as many handsome squares as there are street divisions in the city." Most of the houses are modern, and are built of brick, sometimes stuccoed to resemble stone, which exhibit a beautiful and uniform appearance; and a few of them are constructed of freestone brought from Germany. They are, in general, spacious, having four complete stories, besides sunk cellars and garrets; and those of the nobility in particular are splendid, and elegantly finished in the Italian style of architecture. The shops are as usual confined to the ground story, but as they make no prominent appearance as in most of our cities, they do not disfigure the rest of the building.

Old Copenhagen occupies the western division of the city north of the harbour, and contains the principal public buildings. The palace of Christiansburg, which was destroyed by the conflagration of 1794, and whose ruins still bear testimony to its former magnificence, was erected by Christian VI. out of his own private purse, and is said to have cost six millions of dollars. Its size is out of all proportion either to the extent or the resources of the kingdom; and were we not satisfied of the prudent and paternal administration of its founder, we might have suspected, that it had its origin either in his prodigality or his pride. The front, which is constructed of stone, is 367 feet long, and the lateral sides, built of brick stuccoed, are 389. The elevation is 114 feet, with six stories, of which three are upon a large, and the remaining three upon a smaller scale. The principal suite of apartments is in the fourth story, and the interior decorations were equal to its external grandeur; but so sudden and rapid was the conflagration, that very little of its furniture, pictures, &c. were preserved. The *Ritta saal*, or knight's saloon, was particularly splendid. It was 118 feet by 58, with a gallery on each side richly gilded, and supported by 44 columns of cinnamon wood; and lighted at night by three lustres, which contained more than 1200 wax lights. One of the wings, to which the flames did not extend, still contains the royal museum, or cabinet of rarities, which is ranged in eight apartments in the following order: animals; shells; minerals; paintings; antiquities; medals; dresses, and arms and implements of the Laplanders; and is worthy the attention of the curious. The court of the palace is surrounded with two piazzas, twelve feet deep, supported by Ionic columns, and on each side are magnificent stables, which being arched, have escaped the fury of the flames. In one of these, which contains 48 stalls, each six feet wide, the racks are of copper, and the pillars of the stalls of brick stuccoed; and in another, both racks and pillars are of Norwegian marble. There are also two lateral courts surrounded with buildings; and the whole stands in a kind of island formed by a canal, which communicates with the harbour. The *Kongens nye Tow*, or the king's new market, is a spacious and irregular area situated nearly in the centre of the city. On one side is the castle of Charlottenberg, part of which is now appropriated to the Royal Academy of paintings, architecture, and sculpture; and in the middle of the area, is an equestrian statue of Christian V. in bronze. The observatory, erected by Frederick V. for a disciple of Tycho Brahe, is particularly deserving of attention. It is built in the form of a cylinder, about 70 feet in diameter, and 130 in height, and has a spiral carriage road of brick to within 20 or 25 feet of the top. From the rooms where the astronomical apparatus is kept, there is a very fine and extensive prospect, and it is considered as the most eligible situation for obtaining a complete view of the city, which, with its beautiful spires, elegant streets, numerous canals and vessels, appears like a map spread under our feet. But what gives us most pleasure to contemplate in this quarter of the city, is a simple and elegant pillar of Norwegian granite, situated without the walls near the western gate, and which was erected in honour of the late king, in commemoration of his granting freedom to all the peasants on the crown lands. The four corners of the pedestal are occupied by four figures of white marble, representing peace, plenty, content, and industry; and on marble slabs inserted into the granite, are engraved the following inscriptions: "For Christian den syvende de Danskes og Norskes Konge af eenige og tanknemmelige Borgere." *To Christian the Seventh, king of the Danes and Norwegians, by some grateful citizens.* And on the opposite side: "Grundsteuen bler lagt af Frederik Kongens son Folkets ven, 1792." *The foundation stone was laid by Frederick, the king's son, the people's friend*, 1792. The old town contains also the dock, the exchange, the university, and the royal college, besides several handsome churches and hospitals.

The new town, which was raised by Frederick V. is extremely beautiful, and consists chiefly of an octagon, and four broad streets leading to it in opposite directions. The grand entrance is through a gate, composed of double rows of Corinthian pillars, with a rich entablature. The octagon contains four uniform and elegant palaces, with two wings each; and in the centre is an equestrian statue of Frederick V. which was erected at the expence of the Danish East India Company, and is said to have cost £80,000. One of these palaces is the present residence of the king; another is allotted to the lodging and education of young navy cadets; and the other two are usually occupied by different members of the royal family. At the extremity of one of the streets is Frederick's church, which, though begun many years ago, and though large sums of money have been expended upon it, is left unfinished, and the materials lie scattered over the church-yard. The Danes pretend that the ground is deficient, and that the foundation cannot bear the weight; but it is suspected that the real cause is the want of money. Its plan and style of architecture are grand and elegant, and it was intended to be finished in a manner worthy of the Danish capital. The walls, inside and outside, were all to be of polished Norwegian marble; and one of the blocks, intended as part of a front pillar, ready hewn and polished, Mr M'Donald found to be nine feet in diameter; and "being part of a Corinthian pillar," says he, "the height of that pillar, to make it in due proportion to its diameter, must, pedestal and capital included, have been intended to be about ninety feet." It, however, shews, as well as the palace of Christiansburg, that the Danes have a higher idea of their own consequence than their neighbours are willing to grant; and the ruins of this unfinished church, like some of our own buildings, it is to be feared will long remain a monument of the pride and poverty of its founders. The small Gothic palace of Rosenberg, said to have been built by Inigo Jones, stands near the rampart a little east of the north gate. It contains the state apartments, where the king holds his annual bed of justice; and its gardens, which are very extensive, are the principal promenade of the Copenhageners. In this division of the city, are also the botanic gardens, Frederick's hospital, &c.

Christianshafen is built upon the island of Amak, which is considered the kitchen garden of Copenhagen, and supplies it with milk, butter, cheese, fruit and vegetables, in great plenty. It is connected with old Copenhagen by two bridges across the harbour, and contains the dock-yards where ships of war are refitted, and the marine arsenal. This last was most abundantly furnished with naval stores of every description, before it was plundered by the British in 1807. The magazines, forges, and workshops, are all upon an excellent construction; and the rope-walks are each 1000 feet long. Ship-building, indeed, is nowhere better understood than at Copenhagen, and its admirable harbour can also afford it advantages in this respect superior to those of almost any other city. The harbour of Copenhagen is formed by the straits of Kelleboe, which separate Zealand from Amak. It is capable of holding 500 ships, and lies completely within the fortifications of the town. The entrance is so narrow, that only one ship can enter at a time; and is protected by the cannon of the citadel, and several other batteries, of which the most formidable is that of the three crowns. Ships of the line are thus moored in the very heart of the city with their bowsprits rising above the windows of the houses; and merchant vessels are brought by the canals close to the warehouses that line the quays. Every ship of war has its particular station, with a separate storehouse on the water's edge opposite to where she is moored; and when the Danish navy was in its glory, the scene was truly rich and interesting; but "the fleet is gone," says a modern traveller, "and the view is dismal to those who once saw the harbour and arsenal in Denmark's better days." With the fleet has also departed, in a great measure, the bustle of industry and commerce; and Copenhagen, placed by nature as the emporium of the Baltic, is left to languish in inactivity from the timid and cautious policy of its ruler. Its foreign trade, which was very extensive, was chiefly with Germany, France, Portugal, Italy, and the countries on the Baltic and Mediterranean. Its West India trade was also very considerable; and Copenhagen received almost exclusively the return cargoes from the islands of St Thomas, St Croix, and St John.

Of its East India trade, which was formerly so extensive, and which was rapidly increasing towards the end of the last century, not a vestige remains. During the year 1783, there arrived at Copenhagen 5100 ships, besides 5 from China, 9 from India, and 127 from America; and in 1805 the arrivals were as follows:

Arrivals in 1805.	Ships.
From India and China	24
From America	68
From different foreign ports	1572
From Danish ports	2774
From the ports of Holstein	748
From the ports of Norway	416

The principal domestic trade of Copenhagen is with Norway, Iceland, and the Faro Isles. From the former it draws all its cannon, shot, anchors, and iron-work Russia supplies it with flax, hemp, and masts, and also with some sailcloth and cordage; Sweden with pitch and tar, and Germany with oak. The most valuable manufactures in this city are woollen-stuffs, silk, calico-printing, and porcelain.

Copenhagen is distinguished for its numerous public establishments, and charitable institutions. There are 22 hospitals, and 30 poor-houses. Of these, however, the lying-in-hospital only deserves particular attention, the others being conducted in a manner similar to those of other countries. This institution is an excellent school for medical practitioners, and upwards of a thousand females are annually delivered within its walls. It is open to patients of every country, character, and denomination. All are indiscriminately admitted, without any questions being asked; and they are allowed, if they choose, to be veiled during the whole time of their confinement: the mother is also permitted to leave the child in the hospital, which is frequently done by such of the poorer class as have illegitimate children. Since the commencement of this establishment, the inhuman practice of child-murder has been unknown in this metropolis. The principal literary societies of Copenhagen are, the Royal Academy of Sciences, instituted in 1743, and which has published fifteen volumes of Transactions in the Danish language; the Royal Economical Society, founded in 1768, which possesses an annual income of nearly £1200 sterling, and whose object is to promote the fine arts, fisheries, agriculture, horticulture, &c.; the Medical Society, established in 1772; the Society for Icelandic Literature, in 1779; and a board of longitude in 1784. The state of literature in Copenhagen, however, is rather at a low ebb. Attempts have of late been made by some of its literati to force their language into elegance and popularity, but their compositions are in general clumsy; and in the belles lettres, eloquence, and the higher poetry, they confess themselves still far behind. The Royal Library is a very good collection, consisting of from two hundred and seventy to three hundred thousand volumes. It is principally distinguished for its printed and manuscript editions of the classics, and for an extensive collection of MSS. in the Icelandic tongue, written between the 11th and 14th centuries. Three thousand dollars, which are annually allowed by government for its support, are applied, with classical discernment, in the purchase of the most valuable works that are published, either in Great Britain or on the continent. The press of Copenhagen itself has of late produced specimens of printing equal to those of any other country. The large folio work, *Flora Danica*, and the *Ruris Otia*, are worthy of the first cities of Europe; and an edition of the Four Evangelists, lately printed in Greek, is not inferior to that of either Foulis or Baskerville. The University of Copenhagen was founded by Christian I. in 1479, and has been richly endowed by his successors. It consists of four colleges, and is generally attended by five or six hundred students. The professors have liberal salaries; and 168 poor scholars are provided with lodgings, fire-wood, and three shillings sterling a week. Its library contained about 4000 volumes, chiefly upon theology and jurisprudence, besides about 2000 manuscripts. But the greatest part of its buildings was destroyed by the British bombardment in 1807.

About a mile from the city is the national tomb of the gallant men who fell in the battle of Copenhagen roads on the 2d of April 1801. It is a pyramidal hillock, planted with sapling poplars, with tomb-stones in front, recording the names of the officers who fell, and their respective ships. It is inclosed with a square pallisado; and an obelisk of grey marble, standing on a pedestal of granite, bears the following inscription: "*To the memory of those who fell for their country, their grateful fellow-citizens raise this monument April* 2. 1801;" and beneath, on a white marble tablet, under a wreath of laurel, oak, and cypress, is engraven, "*The wreath which the country bestows never withers over the grave of the fallen warrior.*"

Besides the cathedral, which was destroyed during the last siege, there are in this city 20 churches, one French Protestant church, and several Jewish synagogues.

Copenhagen owes its origin as a city, to a castle which was built here in 1160, by Archbishop Wide, to defend the coast against the pirates which then swarmed in the Baltic. The protection which the castle afforded, and the convenience of the situation as a port, soon induced many of the islanders to prefer it for their residence; and it gradually increased in size and population, until it became the seat of the court in 1443, during the reign of Christopher of Bavaria. Since that time, Copenhagen may be said to have been more than once entirely rebuilt, as there is perhaps not a house in it 200 years old, and the greatest part of them, indeed scarcely above 50. This has been occasioned by the dreadful conflagrations to which it has been frequently exposed; and to which must be attributed its present modern and regular appearance. The fire of 1728, in 48 hours swept away the most elegant part of the city; and 67 streets, containing 1650 dwelling-houses, four churches, the university, and several other public edifices, fell victims to its fury. In 1794, between 900 and 1000 buildings, including the church of St Nicholas, and the royal palace of Christiansburg, were completely destroyed by a similar calamity; and scarcely were the streets rebuilt in the following year, when another part of the city was reduced to ashes. Copenhagen also suffered severely during the last siege in 1807. The cathedral with 305 houses were destroyed, and about 600 damaged by the bombardment; and the number of persons that perished is reckoned at 600, and as many severely bruised. It is to these calamities, however, that Copenhagen owes its present state of beauty and regularity; and, in proportion to its extent, it contains fewer houses that can be called mean, than any town in the world.

The population of Copenhagen has increased considerably during the present century. In 1799, it amounted to 82,608 inhabitants; while in 1806, the return was 95,000. In 1809, however, it was reduced to 90,000. It has, indeed, fluctuated for the last ten years between 85,000 and 100,000. COPERNICUS (Nicolas,) or Zepernick, a celebrated astronomer, and the restorer of the true system of the world, was born near the old gate of Thorn in Prussia, on the 19th of February 1473.* His father was a surgeon in Thorn, and his mother's brother, Lucas Walzelrodt, or Waisselrodt, to whom he owed all his promotion, was Bishop of Ermeland, a situation to which he was raised a few years after the birth of his nephew.

After receiving the first rudiments of education in his native city, Copernicus was sent to study physic at the university of Cracow, where he received the academical degree of Doctor of Medicine. During the prosecution of his medical studies, his mind was constantly directed to mathematical subjects, and he is said to have indulged with particular pleasure in the study of perspective, and in the practice of painting. After attending the mathematical lectures of Albert Brudzevius, his ardour for astronomy received a new excitation; and he aspired to the glory of emulating Purbachius and Regiomontanus, two of the most celebrated mathematicians of his time. With this view he went to Italy,† and received lessons in astronomy from Dominic Maria of Ferrara, who was professor of mathematics at Bologna, and who speedily discovered the great talents of his pupil. From being the pupil, Copernicus became the friend and coadjutor of Maria, and there is reason to believe that Maria's hypothesis of the variability of the axis of the globe, suggested to Copernicus the idea of explaining the celestial phenomena by the motion of the earth. In 1497, Copernicus first observed the occultation of Aldebaran by the Moon.

From Bologna, Copernicus went to Rome, where he employed himself in teaching mathematics, and in making astronomical observations; and such was the respect which his talents had at that time inspired, that after his return to his native country, he was consulted, in the year 1516, by the clergy of Rome respecting the proposed reformation of the calendar.‡ Copernicus had by this time been appointed to a canonry in the chapter

* The date of Copernicus's birth in the text is given on the authority of Mæstlinus, and is reckoned the most probable by Gassendi. Junctinus says that he was born on the 19th January 1472.

† Copernicus is said to have been sent to Italy at the expence of the chapter of Ermeland, but there is no evidence of this, and it is more probable that his journey was the result of an ardent desire to become a great astronomer.

‡ Paul Middelburg, Bishop of Fossombrona, who had made himself known by a work entitled, Magistri Pauli de Middelburgo *Prognostica ad viginti annos duratura*, Coloniæ, 4to, 1484, presided over the council, which was appointed to consider the reformation of the calendar. He wrote several letters to Copernicus, soliciting his assistance on this occasion. This application was strengthened by letters from Copernicus's friend Bernard Scultetus, dean of Frauenberg, who had been chosen secretary by the council; but his mind was engrossed with other pursuits, and he was unwilling to hazard an opinion upon a subject which was not the result of ma-

Copernicus. of Frauenberg, by his uncle the Bishop of Ermeland, and the inhabitants of his native town had nominated him archdeacon of the church of St John. His principal residence, however, was at Frauenberg, and in this sequestered retreat he devoted himself with zeal to the duties of his office, and to the study of astronomy. The house which he inhabited as one of the sixteen canons was situated on the brow of a mountain, and as it commanded a most extensive view, it was particularly favourable for astronomical observations.

The immobility of the earth in the centre of the system was a doctrine universally received among astronomers; and, independently of its coincidence with vulgar observation, it received no small support from the authority of Scripture, and from the still more imposing sanction of Plato and Aristotle. It required, therefore, no ordinary degree of courage to assail a doctrine so strongly entrenched among the prejudices and superstitions of the human mind, and no ordinary degree of genius and abstraction to establish the true system of the world by direct reasoning and observation. Copernicus was particularly struck with the disorder and confusion which prevailed in the Ptolemaic system, and with the absurdity of supposing the planets to revolve uniformly round a centre different from the centre of their orbits; and with the view probably of defending himself by authority as well as by argument, he appears to have begun his inquiry into the true system of the world, by an historical examination of the various opinions which were held by ancient authors.

The opinions of the ancient Egyptians, of Pythagoras, of Philolaus, Aristarchus, Apollonius Pergæus, Nicetas, Heraclides, and Martianus Capella, all countenanced the general notion which he had formed; but it appears* that he attended principally to the system explained by Martianus Capella,† a Roman author of the fifth century, who placed the Sun between Mars and the Moon, and made Mercury and Venus revolve round him as their proper centre; and to the still more complete hypothesis of Apollonius Pergæus, who made the superior as well as the inferior planets revolve round the Sun, while the Sun and Moon revolved round the Earth in the centre of the world.

Guided by these opinions, and by the general principles which he had early entertained respecting the simplicity and harmony of the system, Copernicus was gradually led to the opinion, that the Sun was immoveable in the centre of the universe; that his apparent motion arose from the annual motion of the Earth, which, like all the other planets, revolved round the Sun as their centre; and that all the diurnal phenomena of the heavens were owing solely to the rotation of the Earth about its axis every 24 hours.

After completing this beautiful system, which he had begun to form about the year 1507, he resolved to establish it by the evidence of actual observation. With this view, he determined to make a series of observations upon all the planets, and to construct tables of their motion more correct than those of Ptolemy, or the Alphonsine Tables. He accordingly constructed a quadrant with moveable radii like that of Ptolemy, and also a parallactic instrument, the largest moveable radius of which was divided into 1414 parts, in order to form the hypothenuse of a right-angled isosceles triangle, whose sides were four feet long, and were divided into 1000 parts.‡ With the aid of these instruments, Copernicus made an immense number of observations, which were published along with those of Tycho in 1666, and by means of which he computed his new tables of the planets, and brought to a conclusion, in 1530, his great work on the revolutions of the celestial bodies.

Afraid of alarming the prejudices of the public, Copernicus declined to publish his great work, and resisted the most pressing solicitation of his friends. The Cardinal Nicolas Schonberg, Bishop of Capoua, wrote to Copernicus in 1534, inviting him to publish his new system, and Tydeman Gyse, Bishop of Culm, who appears to have been formerly one of the canons at Frauenberg, made a similar application, in the strongest and most urgent manner. In the year 1539, George Joac. Rheticus, who was Professor of Mathematics at Wittenberg, resigned his chair in that university, and repaired to Frauenberg, for the purpose of making himself master of the discoveries of Copernicus, and they appear to have arranged a method of laying them before the world, without communicating any violent shock to the public mind. In order to pave the way for the work of Copernicus, Rheticus published in the year 1540, but without his name, and under the disguise of a student of mathematics, a general account of the new system. This book was entitled, *Ad clarissimi, v. d. Io. Schonerum, de Libris revolutionum eruditissimi viri et mathematici excellentissimi, reverendi Doctoris* Nicolai Copernici *Torunnæi, Canonici Varmiensis, per quendam juvenem mathematicæ studiosum narratio prima.* Gedani, 4to. The public having received this work without any marks of disapprobation, Rheticus ventured a step farther, and published a second edition of it at Basle in 1541, with his own name, entitled, *De Libris revolutionum Nic. Copernici narratio prima per* M. Georg. Joac. Rheticum. Item, *Borussiæ Encomium, ab eodem.* Basiliæ, 8vo.

In the same year the discoveries of Copernicus were noticed in the most flattering manner by Erasmus Rheinhold, in an edition of Purbachius's *Theoricæ Novæ Planetarum,* which he published at Wittenberg. He speaks of a second Ptolemy being wanted to restore the degenerate science of the age; and, alluding to Copernicus, he expresses a hope that such a person will be found in Prussia, whose divine genius posterity will justly admire.§

Encouraged by the success of these publications, Copernicus at last ventured to put his own work into the hands of Rheticus, which was printed at Noremberg in 1543, at the expence of Cardinal Schonberg, and with the following title, Nicolai Copernici *Torinensis de*

ture deliberation. In the dedication, however, of his work to Pope Paul III. he says, that after he received the application from the Bishop of Fossombrona, he set himself to determine the length of the year and of the month, and the other motions of the Sun and Moon that were necessary for this purpose.

* Copernicus *De Revolutionibus Orbium Celestium,* lib. i. cap. x.

† This author wrote a book in A. D 410, entitled, *De Artibus Liberalibus,* in the 8th book of which he treats of Astronomy.

‡ This instrument was presented by Hannof, canon of Ermeland, to Tycho Brahe, who set a great value upon it.

§ "*Tametsi video,*" says Rheinhold, speaking of Copernicus, "*quendam recentiorem, præstantissimum artificem (qui magnam de se apud omnes concitavit expectationem restituendæ astronomiæ et jam adornat editionem suorum laborum) sicut in aliis astronomiæ partibus, ita etiam in hac varietate motus Lunæ explicanda διαπασων dissentire a forma Ptolemaica.*" And in another place, "*Itaque cum hæ artes jamdiu desiderant aliquem Ptolemæum, qui labentes disciplinas revocet; spero eum nobis tandem ex Prussia obtigisse, cujus divinum ingenium tota posteritas non immerito admirabitur.*"

Copernicus. *Revolutionibus orbium celestium libri vi. Habes in hoc opere jam recens nato et edito, studiose lector, motus stellarum tum fixarum quam erraticarum, cum ex veteribus tum etiam ex recentibus observationibus institutos, et novis insuper ac admirabilibus hypothesibus ornatos. Habes etiam tabulas expeditissimos ex quibus eosdem ad quodvis tempus quam facillime calculare poteris.* IGITUR EME, LEGE, FRUERE. Apud Jo. Petreium. Norimbergæ, in folio. This admirable work its author did not live to read. He received a copy of it, which he saw and touched only a few hours before his death, which happened at Frauenberg, in consequence of the rupture of a blood vessel, and a palsy in his right side, on the 22d of May 1543, three months and three days after he had entered the 73d year of his age.

While Copernicus was pursuing his astronomical discoveries at Frauenberg, his mind was occasionally directed to other objects. He was appointed administrator of the possessions of the chapter in the bailliage of Allenstein, and as he was obliged to reside here occasionally, he had a room fitted up for temporary observations. He is said also to have been appointed to an office in the mint, and to have left a work on that subject, which is still preserved in some town of West Prussia. This fact, however, is stated only on the authority of Count Thadæus Czacki. In 1502, Copernicus went as representative of the chapter of Frauenberg, to an assembly which was held at Graudenz, for the purpose of considering the state of the money system, and he took an active part in endeavouring to effect an uniformity of money in the different provinces of Prussia.

When the bishop happened to be absent, Copernicus was entrusted with the charge of the diocese, and he was chosen general vicar during the vacancies which followed the deaths of two prelates. At the death of Bishop Maurice in 1537, Copernicus was one of the four who were nominated by King Sigismond as the candidates from among whom the chapter of Ermeland were to choose their bishop.

Copernicus appears to have likewise employed himself as a civil engineer. There happened to be no springs of water on the hill of Frauenberg, on which the canons resided: in order to remedy this inconvenience, he constructed, half a mile higher up the river, an oblique dam 15 ells and a half long, and he erected a mill by which the water was raised with a wheel to the top of a tower, from which it was conveyed by pipes to the house of each canon.* This machine, which is now in ruins, is said to have been the model for the great hydraulic machine at Marly.

It is a singular fact in the history of Copernicus, that, while he himself was zealously engaged in establishing a system in direct opposition to the faith of the catholic church, he should have viewed with indifference, and even with hostility, the great reformation which Luther was accomplishing in Germany. An edict was even issued by Maurice, bishop of Ermeland, in 1526, and signed by Copernicus and the other canons,† the first article of which was directed against the exertions of Luther; and it is certainly a remarkable circumstance, that the diocese of Ermeland, illuminated by the wisdom of Copernicus, should have preserved the Catholic religion, while all the surrounding provinces had embraced the doctrines of the Reformation. Copernicus.

About the commencement of the present century, when the science of astronomy was very generally cultivated on the continent, an attempt was made by the Society of Sciences at Warsaw to discover some traces of Copernicus, and Count Thadæus Czacki and Colonel Molski were sent to Frauenburg for this purpose. In the house where Copernicus resided, which was then possessed by an evangelical Lutheran pastor, there were some manuscript verses pasted to the chimney piece, and written in Copernicus's own hand; but about 15 years before, a pastor who had left the place, had carried them off as a memorial of that great astronomer. The name and arms of Copernicus were also painted in colours on a pane of glass, but this valuable relic, after having been preserved three centuries and a half, was also carried off 12 years ago. Over the door of the house is shewn a place where there was an aperture through which the rays of the sun were admitted into another chamber. This aperture, which was probably used as a gnomon, was filled up about six years ago by the present possessor. The tower in the neighbourhood on which Copernicus made his observations, is in a state of bad repair, and is used only for the confinement of prisoners. From a manuscript letter of Copernicus, written a few days before his death to the King of Poland, and dated at Frauenberg, which has been carefully preserved in the archives of Warsaw, it appeared certain that Copernicus had died at Frauenberg, and not at Thorn, as some persons had supposed; and as he was chancellor of the chapter, to which office a particular altar was annexed in the cathedral church, the travellers presumed that he was interred beneath this altar. Near this spot they found a grave-stone, partly covered by a marble ballustrade which surrounds the altar. Spheres cut out in relief, and the letters *Nicol*, pointed out the place where the ashes of the astronomer were deposited. Having obtained permission from the chapter to remove every obstruction, the travellers washed the stone, and found the following letters—

NICOL . . . COP . . . . CUS
AN . . . M

the remainder of the inscription being completely effaced. After raising the stone, they found common yellow sand, and in the middle of it a little black earth, under which were found the remains of mouldering bones. A part of them were kept by the chapter, and five were given to the travellers. The travellers then searched for the manuscripts of Copernicus, but they found only some of his letters on private affairs, and a few of his signatures among the acts of the chapter.

The attention of the chapter having been thus directed to the memory of Copernicus, they ordered a marble to be engraved with his portrait and inscriptions, which has been placed in the wall opposite to the altar where he was interred.

It is impossible to survey the preceding sketch of the life and discoveries of Copernicus, without being struck

* The following inscription was engraven on the tower:—

"Hic patiuntur aquæ sursum properare coactæ,
Ne careat sitiens Incola mentis ope,
Quod natura negat tribuit Copernicus arte,
Unum pro cunctis Fama loquatur opus."

† The edict begins thus:—"Nous Maurice, par la grace de Dieu, Eveque; Jean Ferber, Doyen; Tydeman Gyse, Custos; Jean Sculteti, Archidiacre, *Nicolas Copernic*, Chanoine, et tout le Chapitre des Eglises de la Wurmie ayant consideré, &c."

at the indifference with which the church of Rome witnessed the propagation of a system so adverse to the principles of its faith. More than a century afterwards, when civilization and liberal sentiment had made considerable progress, Galileo was persecuted for holding the same opinions which Copernicus had propagated with impunity. We cannot allow ourselves to imagine that the church was less vigilant in 1530 than in 1634, or that the doctrine of the earth's immobility was less heretical at the one period than at the other. We are therefore led to consider the persecution of Galileo rather as the consequence of his personal imprudence, than of his astronomical opinions, and to imagine that the cardinals had seized the opportunity which the publication of his dialogues presented, of gratifying a private resentment, which might possibly have been well-founded Upon what other supposition can we account for the extreme severity of the church against the Pisan philosopher, and for its total indifference to the same crime in the canon of Ermeland. The publication of Copernicus's system gave no shock to the public mind; the religious feelings of no individual, and the watchful jealousy of no tribunal, were alarmed. The most distinguished members, on the contrary, of the Catholic church, encouraged and promoted the propagation of the new system. The Cardinal Nicolas Schonberg pressed Copernicus to publish his discoveries. The Bishop of Culm employed his influence in the same cause. The work was dedicated to the Pope himself.† The King of Poland even proposed him a candidate for the vacant bishopric of Ermeland; and 38 years after his death, Cromerus, Bishop of Ermeland, erected a monument to his memory. The charge of heresy was never preferred against Copernicus either during his life, or after his death; and we have never been able to discover, that the slightest disapprobation had been either cherished or expressed against his system of the universe. Had Galileo been canon of Ermeland, and Copernicus professor of mathematics at Pisa, religion would never have been degraded by the persecution of the philosopher, nor science afflicted at the ignominious compromise by which it was averted. See Gassendi *Nicolai Copernici Varmiensis Canonici Astronomi illustris vita*, published at the end of the life of Tycho Brahe; and Bernoulli's *Travels*, vol. iii. page 18. (β)

COPROSMA, a genus of plants of the class Polygamia, and order Monœcia. See BOTANY, p. 343.

COPTS, a name given to the descendants of the ancient Egyptians, who profess the Christian faith, according to the Jacobite or Eutychian heresy. They consider the name Copts as a nickname, and call themselves by the name of Jacobites, from Jacobus Zanzales, bishop of Edessa, who travelled over a great part of the East, to propagate the doctrine of one nature in Christ, and died in the year 578.

The Copts have a patriarch, or metropolitan, at Alexandria, who is head of the whole Coptic church, and is said to have one hundred and forty bishoprics in Egypt, Syria, Nubia, and other countries, subject to his patriarchate, besides the Abuna of Abyssinia, who is also nominated and consecrated by him. The Coptic church has been so grievously oppressed by the government, that both clergy and laity labour under the most miserable poverty, attended by its usual associate, deplorable ignorance.

Eutychius, patriarch of Alexandria, was the first who maintained the Monophysite doctrine, or the doctrine of one nature in Christ; for which he was excommunicated, and died in exile. Shortly after, however, his party, with Dioscorus at their head, called a council at Ephesus, in opposition to that of Chalcedon, which had condemned Eutychius; and, in their turn, excommunicated the pope, and all the bishops who adhered to him. This is the origin of the fatal breach between the Latin and Alexandrian churches, which has continued ever since, in spite of all the efforts of the church of Rome to effect a union. Dioscorus did not long enjoy his triumph; he was anathematized, and banished; and Prolerus, whom the court of Constantinople had nominated his successor, was assassinated in the cathedral on *Good Friday*, 477, on a sedition raised by the Monophysites, who had already chosen another patriarch.

From that time there have been two patriarchs; the one of the Greeks, styled orthodox, the other of the Copts, called schismatics. The Greek party continued for a considerable time to maintain the ascendency, till the doctrine of the Copts was revived, and their party strengthened, by the preaching of Jacobus Zanzales, from whom they assumed the name of *Jacobites*. The Jacobites were always discountenanced by the government, and denounced as heretics by their more powerful rivals in the church, till the invasion of Egypt by the Turks; when, in hopes of being revenged on the Greeks, or of obtaining better terms from the Infidels, than under the government of professing Christians, they readily joined the invaders, and, it is said, outdid the Turks in their hatred and cruelty to the Greeks. In consequence of this alliance with the conquerors, they obtained a confirmation of all their former privileges, and enjoy, from the Turks, a superiority of regard over their rivals the Greeks.

With respect to the rites of the Coptic church, circumcision is universally adopted, and considered so essential, that it is administered to both sexes. (See CIRCUMCISION.) Baptism is not considered as so necessary. Confession is admitted; but instead of a private, auricular, and particular confession of sins, a public and general one is admitted; and the sinner obtains absolution on very easy terms. The Copts are particularly strict in their fasts, during Lent and Advent, when they eat neither flesh, fish, fowls, nor eggs, and use neither butter nor oil. Children of ten years of age, and also the sick and the dying, are compelled to observe the same strict abstinence, which is, in some de-

† There is a curious passage in this dedication, where Copernicus states, that the reason of inscribing his book to his Holiness was, that the authority of the pontiff might put to silence the calumnies of some individuals, who attacked his system by arguments drawn from passages of scripture twisted for their own purpose. As the passage is peculiarly interesting, our readers will be gratified with the original words. "Ut vero pariter docti, atque indocti viderent, nullius omnino subterfugere judicium, malui tuæ sanctitati, quam cuiquam alteri has meas lucubrationes dedicare; propterea quod et in hoc remotissimo angulo terræ, in quo ego ago, ordinis dignitate et literarum omnium, atque mathematices etiam amore eminentissimus habearis; *ut facile tua auctoritate et judicio calumniantium morsus reprimere possis*; *etsi in proverbio sit non esse remedium adversus sycophantæ morsum.* Si fortasse erant *ματαιολογοι*, qui cum omnium mathematum ignari sint tamen de illis judicium sibi sumunt *propter aliquem locum Scripturæ male ad suum propositum detortum, ausi fuerunt* meum hoc institutum reprehendise ac insectari; illis nihil moror, adeo ut etiam illorum judicium, tanquam temerarium contemnam."

gree, rendered necessary by their extreme poverty. The marriage service is read by the priest in the ancient Coptic, which is now understood by few even of their learned clergy. Divorce is allowed on very frivolous pretences; and may be prosecuted by either party, on the mere grounds of a simple dislike.

In short, the rites and doctrines of the Coptic church are much the same as those of Abyssinia, where they form the established religion of the country, and are strictly and universally observed.

The patriarch of Alexandria is chosen by the bishops of the Coptic church. He is first installed in the great church of St Macarius, at Cairo, where he is elected; and afterwards at that of St Mark, at Alexandria. He is obliged to preach once a year to his clergy; whilst their employment is to read, on set days, homilies and legendary tales to the laity. The person next in dignity to the patriarch of Alexandria, is the titular patriarch of Jerusalem, who resides at Cairo; and visits Jerusalem every Easter, together with the other places in Palestine, which acknowledge his jurisdiction. He has the government of the Coptic church during a vacancy of the patriarchal see.

Many ineffectual attempts have been made to unite the Coptic to the Roman church. About the year 1560, the patriarch of Alexandria wrote a letter to the Pope, in which he seemed to acknowledge his authority, stiling him *father of fathers, pastor of pastors,* and *master of all churches.* The Pope, overjoyed at this apparent submission, sent a nuncio to Alexandria, with a sum of money to the patriarch. After the money was delivered, the nuncio was informed, that the designations which the patriarch had given to the Pope in his letter, were merely complimentary titles, which he occasionally bestowed on his friends; and that each of them must still remain the head of his own church.

There have been many disputes about the origin of the word *Copts.* Scaliger first supposed it to be derived from Coptos, a celebrated town of ancient Egypt: he afterwards supposed it to be derived from the word Αιγυπτος, by omitting the first syllable. The objection to both these etymologies is, that *Copts* is entirely a modern appellation, not known before the conquest of Egypt by the Mahometans. Others have again supposed, that, as the name is confined entirely to the *Jacobite* Christians, it is merely an abbreviation of this word by omitting the first syllable, making Cobite, and hence Copt by an easy mutation. Many other etymologies have been proposed, all equally uncertain and unsatisfactory. (*v*)

COPYHOLD, in the law of England, is a species of land tenure, which is evidently the offspring of the ancient tenure in *villenage.* It is so called because the tenant holds his lands by copy of court roll of the manor, at the bill of the lord.

Villeins might, anciently, be enfranchised either by express or implied manumission, to which law and practice were extremely favourable. In process of time, the villeins, by a series of encroachments on their lords, came to have a more secure and permanent interest in their possessions; and, at length, the common law gave them a title to prescribe against their lords, so that, when they and their children had continued to enjoy their lands, time out of mind, by a regular course of descent, they began to be called tenants by copy of court roll, and their tenure itself a copyhold. These lands, therefore, were now no longer held at the mere will of the lord, but at the will of the lord *according to the custom of the manor;* and so long as he conformed to that custom, the tenant could not be ejected. Tenure in villenage was virtually abolished by the statute of Charles II. but copyholds were reserved.

In order to constitute a copyhold tenure, it is necessary, 1st, That the lands be parcel of, and situate within, that manor under which they are held; and, 2d, That they have been devised, or devisable, by copy of court roll immemorially; for, strictly speaking, no new copyhold can be granted at this day. See Blackstone's *Comment.* b. ii. ch. 6. (*z*)

COQUIMBO, or LA SERENA, the capital of a province of the same name in Chili, was founded by Valdivia in 1544. It is situated in the valley of Coquimbo, from which it receives its original name; but Valdivia called it La Serena, from the province in Old Spain in which he was born. The town is delightfully situated at the distance of a quarter of a league from the sea on the river Coquimbo, and commands an extensive prospect of the ocean, the river, and the surrounding fields and woods. The streets are straight and broad, and stretching from north to south, and from east to west, they form squares of buildings, the wide spaces between the squares being entirely occupied by gardens planted with fruit trees and esculent vegetables. The houses are built of mud and covered with leaves, and their mean appearance is taken away by the richness of the gardens.

The principal public buildings are the parish churches, five convents belonging to the Franciscans, the Dominicans, the Augustines, the Fathers of Mercy, and to St Juan de Dios, and a college formerly belonging to the Jesuits. The churches belonging to these orders are large and respectable. The parish church forms part of the great square, and on the opposite side is the town-house where the corporation meets, which consists of the corregidor, the alcaldes, and the regidores. The river Coquimbo runs on the north side of the town, and by means of canals supplies the town with water for the use of the gardens. There is a fine bay at the mouth of the river, where ships can ride in security, and at the port of Coquimbo, two leagues distant from the city, several vessels from Peru load annually. When Ulloa visited Coquimbo, the population did not exceed four or five hundred families, consisting of Spaniards, Mestezos, and a few Indians. West Long. 71° 19′ 15″, South Lat. 29° 54′ 40″. See Ulloa's *Voyage to South America,* book viii. chap. viii. vol. ii. p. 267, and Molini's *Account of Chili,* vol. i. p. 296. (*π*)

CORAL FISHERY. The ornamental purposes to which coral has long been applied, and the confidence in its virtues entertained by the older physicians, have rendered its acquisition an object of considerable anxiety. The quantities accidentally detached from submarine recesses, and occasionally washed ashore, being insufficient to supply the demand, different means have been adopted to withdraw it from the places of its natural vegetation.

The more valuable species of coral are peculiar to the warmer climates; and in some of these, divers are accustomed to descend in quest of it, carrying down a sponge dipped in oil. As the effect of oil is to tranquillize the surface of the sea, by allowing a small portion to escape, the waves are lulled, and light can penetrate below. But coral being generally produced at great depths in the sea, and requiring both time and

Coral Fishery.

labour in the collection, other means have been employed, and regular fisheries established for that purpose, particularly in the Mediterranean and Adriatic.

The principal implements in use are, in France, called *engin* and *salabre,* which latter is in Italy denominated *ordigno.* The former is a long spar, retained by two cords from above, and sunk by a weight in the middle: one end is provided with an iron hoop eighteen inches in diameter, opening into a strong hemispherical net. At the opposite sides of the hoop are other two nets, approaching to a triangular or conical form, descending far below. The second implement consists of two long cross spars fixed in the middle, through which a cord passes for retaining it above, and where also a cannon shot is lodged to carry it down. At each of the four extremities of the spars there is a large deep pyramidal net, with meshes of unequal width. These implements are carried out to sea in barks manned by the stoutest fishermen; for it is a service both of fatigue and danger: in some fisheries, the spar of the former implement exceeds the total length of the bark, and is lowered from the side; whereas in others it is shorter, and for safety lowered from the stern.

But, in order to understand how such unwieldy implements may be successfully employed, it is necessary to consider the natural site of coral. Those who have had the best opportunities of observation unite in affirming, that this substance is almost invariably produced in submarine caverns, or on shelving rocks. In the former, it is larger, more abundant, and of greater value. Besides it is usually deep in the sea, as already observed. When the first implement is applied therefore, it is cautiously lowered from the bark, and by means of the two retaining cords, guided under the projecting rocks, or into the recesses below. There the branches of the coral being entangled, are forcibly broke off; and if the stem with the root can be obtained, it is deemed a valuable acquisition; for the great difficulty in fishing coral is to procure it entire. The other implement takes a wider range, and in addition to being used somewhat in an analogous manner, it is employed to recover the portions of coral broken off and lying at the bottom of the sea.

Marsigli affirms, that coral is most abundant in caverns exposed to the south, and where the sea is smooth and tranquil: that it is seldom found in a western exposure, and never to the north. This is in general true, but the tranquillity of the sea is not indispensible to its copious production; and from this results the danger which frequently attends the fishery. Experienced fishermen, aware of the places where it should be found, search them out with extraordinary care and diligence, and the first discoverer is sure to enrich himself by it. But a cavern, however fertile, must be visited at certain intervals; for although the coral, of which it is despoiled, will be renewed, it is only after the lapse of a considerable time. Marsigli judiciously observes, "that a forest of coral may be compared to a terrestrial forest; and after the caverns containing it have been ransacked, a certain interval must be allowed for its renewal. But the sea not being under restricted dominion like the land, the same order cannot be preserved, which is adopted for the renewal of forests. Thus fishermen, by continually resorting to the same places, prematurely break and destroy the growing coral, which time would otherwise bring to perfection."

Marsigli's remarks are corroborated by other philosophers; and the first discoverer of a cavern will reap a fertile harvest, while those who follow can gain little, unless discretion attends their search. But the discovery of such caverns is not reserved for fishermen solely, as Donati, a distinguished naturalist, relates, that by means of the implements above described, he succeeded in finding one of great extent and uncommon fertility in coralline products, at Porto Rosso, in the Adriatic. In illustrating the necessity of a considerable interval being allowed to elapse between the successive fisheries of coral within the same limits, the Abbé Spallanzani informs us, that, in the Strait of Messina, this interval is ten years. The tract occupied for the fishery is divided into ten parts, and one of these only resorted to within the prescribed period of ten years, whereby sufficient time is admitted for the regeneration of the coral, while the fishery is uninterruptedly prosecuted during the season allotted for it. When this law, resulting from experience, is infringed, coral is obtained indeed, but of inferior quality. The most intelligent fishermen maintain, that, in ten years, red coral attains its extreme height, which is about a foot, and that its thickness is scarcely increased ever after; and likewise, that at very great depths, its vegetation altogether ceases. Spallanzani, in considering this fact, observes, that coral fished up from the neighbourhood of San Stefano, where none had been sought within the memory of man, though of a bright red colour, was not higher than ordinary coral, and exceeded it by only about a third in thickness. In certain situations, however, it does not attain the height of half a foot in ten years.

The principal coral fisheries with which we are acquainted are carried on at Marseilles, in the Strait of Messina, and at the Lipari Islands. With regard to the latter, eighteen or twenty barks, belonging to the port of Messina, are employed in it. Each is manned by eight seamen, who are inured to this pursuit, and well acquainted with the navigation of the surrounding seas. They are not exclusively devoted to the fishery, which is followed only when they want other employment; but it is necessary that they should be stout and hardy, both from the attendant labour, and the danger of the occupation. The quantity of coral annually obtained by these vessels is said to exceed 3000 pounds, of various quality, both of a white and red colour, and of different shades. The size and fineness of the coral regulate the price; some is reputed worth ten guineas an ounce, and some is scarcely valued at tenpence a pound; the oldest is the deepest in colour, which is accounted a quality; and there are reckoned no less than nine different shades, from dark crimson to pale carnation. White coral, which is also obtained in the Straits of Messina, is of different shades; but red is the most valuable, and the most constant object of research.

During the months of June and July, the coral fishery of the Lipari Islands is carried on by fifteen barks, but less successfully than in the Straits of Messina. Whether because the substance is exhausted, or the fishermen not equally skilful, each bark, in a particular season, has not collected above 30 or 35 pounds of coral. The superstitions of the people are known to affect such pursuits; for, some years ago, several barks having been cast away in the Mediterranean, a Dominican friar menaced the mariners and others with excommunication, should they prosecute their enterprize. Nothing could be more effectual; and the fishermen, to preserve their peace with the church, were content to forego one of their sources of subsistence.

Formerly the coral fishery of Marseilles was in a flourishing condition, and the barks belonging to it brought great quantities of coral from the African coast; but we are not acquainted with its present state. Most of the coral obtained in the Mediterranean is carried to Leghorn, and from thence dispersed to other countries.

Where coral is situated at great depths, the fishermen cease to search after it, owing to the imperfection of the plant, and the labour of obtaining it. The greatest quantities are recovered from the depth of 60 to 125 feet; and some fisheries are carried on to the depth of 900 feet. "In the Straits of Messina, the grottoes productive of coral are situated nearly in the middle, and at various depths, from 350 feet to 650. The depth increases on advancing towards the mouth of the Strait, where the fishery is no longer prosecuted, the rocks, according to the coral fishermen, being there 1000 feet from the surface." At the depth of 900 feet, it is supposed to require 40 years to attain the same size which it would do in 10 years at 60 feet.

Sometimes, though rarely, the fishermen recover coral, which has another origin than in caverns. Founded on an adventitious substance, it springs perpendicularly from the bottom of the sea, and in this way the plant is obtained entire. By an invariable law, its growth is perpendicular to the plane of position whatever that may be; and in Marsigli's opinion, when produced in submarine caverns, it always depends perpendicularly from above. Branches broke off continue in favourable situations to vegetate, whence, if the root is once secure, the stem rises upwards. But these are considered rare instances, and are rather to be viewed as aberrations from the laws which regulate the production of coral. The implements of the fishermen are therefore adapted both to withdraw the coral from recesses, and to recover it either when falling down to the bottom of the sea, or when growing there.

As the coral fishermen cease to search for that substance at very great depths, neither do they frequent shallows; for it is said that none grows in less than ten or twelve feet of water. By this is probably meant the *Gorgonia nobilis*, or red coral; for there is reason to believe, that in certain climates other species vegetate until they approach the surface. Whole islands, particularly in the East, are said to originate from a base of coral. The animal by which it is formed discontinuing its labours when gaining the surface of the sea, leaves a basis for the accumulation first of earthy and then of vegetable matter, which by gradual accession interrupts the progress of the waves. Hence it has been proposed to guard an open coast by transplanting coral beds for the formation of barriers to the sea: and an instance is quoted of a survey being made on the coast of Sumatra in the year 1784, when two feet and a half of water was found on a shoal. But four years and seven months afterwards the rudiments of an island ten yards in diameter, and bearing a few bushes, was visible on the spot; thus it is probable we are still unacquainted with the greatest and least depths of the growth of coral; and as it is solely of animal origin, many observations made in the conviction of its being a vegetable product are to be received with distrust. See Spallanzani *Viaggi alle due Sicilie*, tom. v.; Tournefort *Voyages*, tom. i. p. 17.; Donati *Storia del Mare Adriatico*; Marsigli *Histoire Physique de la Mer*. (c)

CORCHORUS, a genus of plants of the class Polyandria, and order Monogynia. See Botany, p. 235.

CORCYRA. See Corfu.

CORDAGE. See Rope Making.

CORDIA, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 142.

CORDOVA, the *Corduba* of the ancients, is a city of Spain in the province of Andalusia. It is delightfully situated on the north bank of the Guadalquivir, which winds round its walls in the form of a crescent, at the entrance of a spacious plain, which is bounded on the north by branches from the mountainous ridges of the Sierra Morena.

The town, which is nearly of a square form, stretching from east to west, is defended by walls flanked with large towers. It occupies a great space of ground, part of which is covered with gardens and orchards, and its suburbs are sufficiently large to resemble so many separate towns. The largest of these is the suburb to the east of the town, where there are a great number of mills erected on the Guadalquivir. The general appearance of the town is gloomy, the streets being narrow and crooked. The principal square is very spacious, and consists of houses regularly built, and having porticoes all round it. The individual houses in Cordova have, in general, a tolerable appearance, particularly from the fine gardens which are attached to them.

The principal public buildings at Cordova are the cathedral; 15 parish churches; 40 convents for both sexes; the episcopal and the royal palace, two colleges, and 21 hospitals.

The cathedral, which is an old mosque, retaining its original name of Mezquita, was built in the year 170 of the Hegira, on the site of the old Gothic cathedral, which also stood upon the site of the temple of Janus. It is an insulated building of enormous magnitude, conspicuously situated at the meeting of four elegant streets. Its length is 534 feet, and its width 387½ feet. Bourgoanne makes its length 620, and its breadth 440 feet. The stones of which the walls are built are 3½ feet long, 1 foot 9 inches wide, and 6 feet 10 inches thick, and the walls are of different heights, in consequence of the inequality of the ground, which is 30 feet high on three sides, and about 42 on the south side. The north front is covered with exquisite stucco ornaments, and before the door are six beautiful jasper columns, 4 feet 9 inches high. An elegant tower 51 feet 8 inches wide on each face, rises on one side, and its 14 windows are adorned with columns of black and red marble. The tower terminates in a number of small arches, like festoons, supported by similar columns, which, with those of the windows, amount to 100. Before the entrance of the temple is a space 180 feet long, surrounded on three sides with a handsome portico, supported by 72 columns. Below it is a capacious arched cistern, which is sustained by columns, and from the cypress, orange, citron and palm trees, with which the area is planted, and the *jet' d'eaus* which are continually playing, it resembles a garden in the air. There are 17 doors in the cathedral covered with curiously wrought bronze plates, but only five of these are used.

Opening into this area, and running from north to south, are 19 large aisles 350 feet long and 14 broad, having their ceilings of fragrant woods, and there are 17 smaller ones crossing from east to west. They are divided by rows of columns to the number of 850, which, with those of the tower and portico, make 1018,—an assemblage of columns which is perhaps unexampled in the world. These pillars, which are principally of the finest marble, vary from seven to eleven feet three inches in height, and have, in general, Corinthian capitals.

Cordova.

Separated from the rest of the cathedral by a square building, is the chapel in which the Moors preserved the book of the law. It is adorned with fine marbles, and the entablature is supported by 12 columns placed upon the shafts f other 12. It has also a handsome dome. This building is succeeded by another square one, which has a cupola supported by 84 columns of fine marble, and 8 windows with sky lights in alabaster. This building leads to a magnificent octagon, 13 feet in height and width, and ornamented with marbles like the other buildings. In 1528, the cathedral was formed into a cross, by building a chapel in the middle, forming as it were a second church. This venerable building, of which we are able only to give an imperfect account, was visited by the Moors from Africa, even after it had fallen into the hands of the Castilians.

The church of the Martyrs, which belongs to the Dominican convent, is a handsome and ancient building, and contains several fine paintings, with a beautiful marble monument of Ambrosio Moralez. The church of the Capuchins, and that of St Francis also, contain several paintings of great merit. The royal palace, which resembles a citadel, is a large and handsome building, encircled with walls, and situated at one of the extremities of the town. A great number of horses used to be kept in the stables for the king of Spain; and in 1792, there were no fewer than 600 of all ages.

The Episcopal palace, which was occupied by the Inquisition, is a large building, with a noble marble staircase. It has a spacious garden, and a little wood of orange trees. It contains a number of good paintings, and one of the halls is filled with a long series of paintings of the bishops of Cordova.

The college of St Paul, which belongs to the Dominicans, is reckoned one of the finest edifices in Cordova. Its front is of marble, and it has also a magnificent marble staircase. The cloister is particularly fine, consisting of two ranges of porticoes one above the other, and supported by 80 marble columns. The library contains many choice books, and the church some good pictures.

A school for drawing, in which a number of young people without fortune are supported, was established by Bishop Don Antonio Cavalleros, and in 1801, it was under the direction of a painter, a sculptor, and an architect.

Cordova was a commercial town in the time of the Romans. Under the Moors, and also under the Castilians, it carried on a very brisk trade, and could then boast of several celebrated manufactures of silk and gold lace, which are now gone to decay. The principal trade and manufactures which are now carried on, are those of ribbands, lace, hats, and baize. Gold and silver articles are still manufactured here and sent to the fairs. Their store-houses are rich, but their work is neither delicate nor elegant; and although the art of softening leather and giving it a fine polish was invented at Cordova, yet the town possesses few tan-yards.

One of the principal places in the environs of Cordova is the bishop's country house, which is a mile and a half from the town; its gardens and walks are truly magnificent, and the collection of exotic medicinal plants is large and valuable. Though the surrounding mountains are craggy, yet they are covered with gardens, vineyards, and forests of olive and fruit trees. The air is perfumed with the flowers of the orange and the citron tree; and the oranges and citrons are sold for almost nothing in the market, and towards the end of autumn are used for manure.

In the time of the Moors, Cordova is said to have contained a population of 300,000. When the Moors were expelled by Ferdinand, that prince and his successors endeavoured in vain to recruit the population of Cordova; so that about the middle of the seventeenth century, it had decreased to 60,000. When this town was visited by Bourgoanne, the population did not exceed 35,000. See Laborde's *View of Spain*, vol. ii. p. 29; Bourgoanne's *Tableau de l'Espagne;* Semple's *Second Journey in Spain;* Dillon's *Travels through Spain;* and Fischer's *Travels through Spain in* 1797 *and* 1798. (π)

Corduroy.

CORDUROY, (*Cord du Roi*, or *King's Cord*), originally a stout manufacture of silken cloth, but now imitated in cotton goods, which are manufactured to an immense extent in Lancashire, Cheshire, and the western district of Yorkshire. In whatever part of Europe this manufacture was first exercised, it is evident from the name that we derived it from the French; and as it is composed entirely of cotton, its introduction into Britain must be very recent, probably not exceeding 40 or 50 years at the utmost. There are immense varieties of this article manufactured, but the chief are those distinguished by the names corduroy, thicksett, velverett, and velveteen, all of which are merely varieties of pattern in imitation of the Italian and French velvets. In the general article CLOTH MANUFACTURE, a few remarks are introduced relative to the general principles of their fabrication, and a section of them to shew the nature and geometrical principle of the texture, is given in Plate CXCIII. Fig. 10. attached to that article. As an article of common consumption, these goods are found so effectually to combine the desirable requisites of cheapness and durability, as to have brought them into almost universal use with the great body of the people, both at home and abroad, in so far as their exportation is not either prevented or limited by the effects of the war. As the combination of the greatest possible quantity of stuff within the smallest compass is considered as the chief excellence of these goods, they are not paid by any fixed measure of length, but in proportion to the weight by which the cloth when woven exceeds that of the warp when delivered to the weaver, or, in other words, in proportion to the quantity of woof which the weaver is able to interweave with his warp. Thus the weaver is stimulated by his own interest to make the fabric as thick as possible, and this is found to be the best practical plan for procuring goods of this kind sufficiently dense in the fabric. It is, besides, a conclusive proof, that no excess can possibly be apprehended. The ground-work of the fabric is sometimes of plain and sometimes of tweeled cloth. The former being produced somewhat cheaper, is sometimes, although very injudiciously, preferred by poor people; for, from its superiority of strength, the best tweeled fabrics or backs, as they are called, are by very far the cheapest ultimately. The pile being raised in the same way as velvet, is also cut after the web has been taken from the weaver, when the subsequent operations of dyeing and dressing having also been performed, the cloth is ready for the market.

PLATE CXCIII. Fig. 10.

In order to enable those who have not had opportunities of seeing the process of this manufacture, but who may be sufficiently conversant with the practice of weaving other stuffs as to be acquainted with the nature and application of the plans by which the order and succession in which the warp is inserted in the heddles, or healds, of a loom, and the connecting cordage between these and the treddles disposed, a few plans are subjoined of the principal varieties of these articles.

Those who are not previously acquainted with the intention and use of these plans, will find these particulars explained in a future article. For the present it may be sufficient to observe, that the order in which threads of warp through any number of leaves of heddles are drawn, is denoted by the succession of figures or numerals 1, 2, &c.; that the number of treddles is found by the cross checkers at the left hand of the plan, and that those connecting cords which raise a heddle are distinguished by cyphers, while those which sink it are denoted by blanks. The succession of moving the treddles is pointed out by the numerals below. (J. D.)

COREA, or Korea, a peninsular kingdom of Asia, dependent upon China, called *Kao-li* and sometimes *Chau-tsien* by the Chinese, and *Salho* by the Mantchew Tartars. It reaches from the latitude of 34° 32′ to 43° 10′ both N. and from the longitude of 125° to 131° 34′ both E. from Greenwich, measuring about 500 English miles from N. to S. and 200 of medium breadth from E. to W. so that its area contains about 96,000 square miles, or 62,440,000 statute acres. At one period of its history Corea is said to have contained 690,000 families; which would then give a population of about three millions and a half, or one person to every $17\frac{1}{4}$ acres. On the north it is separated from Maudshuria by a chain of mountains, stretching from E. N. E. to W. S. W. On the north-west from the Chinese province of *Leao-tong*, by a continuation of the same mountain range, and a barrier of palisades or wooden piles. On the west it is separated from China by the gulf of *Leao-tong* and the *Hoang-hay* or Yellow Sea. It is bounded on the east by the Sea of Japan; and is separated on the south-east from the insular kingdom of Japan by the straits of Corea, which are about 86 English miles in breadth, and contain several islands.

The interior geography of this distant peninsula is very little known, as it is inaccessible to European commerce, owing to the jealous precautions of the paramount Chinese government, which limits all foreign intercourse to the port of Canton. It is represented as divided into eight large provinces, containing forty inferior districts, in which there are said to be thirty-three cities of the first class, fifty-eight of the second, and 70 of the third. Its chief rivers are, the *Ya-lou* on the N. W. the *Tou-men* on the N. E. both said to take their rise from a very high mountain, named *Chan-pe-shan* by the Chinese and *Shanelin* by the Mantchews, both names signifying the *ever white mountain*, indicative of its being perpetually covered by snow. There are also the *Li* on the W. and the *Han* on the S. E. besides many other inferior streams on its eastern and western sides. The whole interior of the country is also represented as intersected in various directions by many ranges of hills, dividing it into numerous vallies. *King-ki-tao*, in the central province of *King-ki*, is the capital; and the other principal cities are *Ouei-yuen* in the N. W. *Kiang-si* or Ping-gang in the W. and *Tcin-tcheou* in the S. Several islands are scattered along all the three sides of this peninsula that are washed by the sea, the largest of which, named *Quel-paert* or *Kel-praet*, is on the S. being upwards of forty miles in diameter, and nearly sixty miles from the continent, the intervening sound being studded by a great number of smaller islands.

According to Perouse, the whole southern coast of Corea, from Quel-paert eastwards, until past the S. E. cape of the peninsula, is thickly strewed with dangerous rocks and islands, for the distance of twelve or fifteen miles from the coast; after which, that navigator was able to steer close to the continental shore, being able to distinguish the towns and houses on the coast, and to view the bays as he sailed along. He also mentions having seen many fortifications on the tops of the hills, exactly resembling European forts, probably intended for defending the country against invasion by the Japanese. He reports the eastern coast of Corea to be favourable for navigation, and free from dangers, the sea at three leagues from the coast being every where about sixty fathoms deep, on a bottom of mud. The country appeared every where very mountainous, and the soil seemed arid, and but little susceptible of cultivation. The climate also seemed ungenial, as the snow was not entirely melted in some hollows among the hills in May 1787. A dozen or more junks or sampanes were seen under sail on different parts of the coast, resembling in all respects those in use among the Chinese.

Though mountainous, Corea is said to produce abundance of wheat and rice; and ginseng, a favourite medicine in China, is among its productions. From a species of palm found in this country, a gum or balsam is extracted, of which a yellow varnish is prepared, said to be little inferior in beauty to gilding. It also produces gold, silver, iron, fossil salt, with sables and beaver skins; but the two last are more likely to be only transmitted through Corea, by means of trade or barter, from Maudshuria, and the north of eastern Asia. It has a breed of small horses, only three feet high; and the hens of Corea are said to have tails three feet long, though these are more probably some species of pheasant. The paper of Corea, made of cotton, is in great request in China, for being used, when oiled, in their windows, as it is very strong, and resists the effects of wind and rain. The Chinese also employ it as wrapping paper, and for lining clothes; and from its description, as susceptible of being split into several strong layers, we suspect that it may be manufactured from the bark of some species of plant, in the same manner with what is called Otaheite cloth. Small brushes for painting, made from the tail of some species of wolf, are sent in great numbers to China, where they are said to be much valued. The sea coasts abound with fish of various kinds; and many whales are found every year towards the north-east, some of which are said to have the harpoons of the European whale-fishers sticking in their bodies, and must consequently have come all the way from Greenland through the Arctic Ocean, along the north coast of Asia or America, and by Beering's Straits, into the Seas of Kamtshatka, Jesso, and Japan.

The Coreans are described as stout and well made, of mild and docile dispositions, much addicted to the learning of the Chinese, and fond of music and dancing. They are also brave, and the northern provinces especially produce a stout and active race of men, who make excellent soldiers, using cross-bows and very long sabres. Their houses are generally mean, and consist only of one story; those in the country being constructed of earth, while those in the cities and towns are built of brick, but all are thatched with straw. Their cities are walled after the Chinese manner, having battlements, square towers, and arched gateways. Their dress, writing, religious ceremonies, and most of their laws and customs are borrowed from the Chinese; but their spoken language is entirely different. Their women are subjected to fewer restraints than in China, and the marriages of their young persons are not, as in that country, entirely directed by the will of parents. They do not inter their dead till three years after their decease, on which occasion they place round the tomb or grave the clothes, chariot, and horses of the deceased, and every thing else of which he was particularly fond during his life; all of which are left to be carried away by the assistants at the funeral. They mourn three years for a father or mother, and three months for a brother.

The original natives of Corea were probably of Tartar descent, and are said to have anciently consisted of various tribes, all of which coalesced in the sequel into one kingdom. The history of Corea, as given from Chinese authorities by Du Halde, is altogether unworthy of attention. This kingdom is stated to have been subject to China, no less than 2357 years before the Incarnation, and to have become a separate monarchy under a Chinese prince, named *Ki-tse*, to whom the laws of Corea are attributed, 1122 years before Christ. He is said to have been succeeded by a regular line of independent sovereigns until 264 years before Christ, when the country was again reduced to become tributary to China, and since then it has always followed the fortunes of that empire. About the end of the 16th century, the Japanese invaded Corea, and nearly reduced it to subjection; but were again expelled by the Coreans, assisted by the Mantchew conquerors of China, their over lords. At this time the Mantchews endeavoured to compel the Coreans to shave their heads after their manner, and to adopt the Tartar dress; but this attempted innovation irritated the Coreans, and occasioned a general revolt, which was at length appeased by the prudence of the Chinese government; and the country has ever since enjoyed peace and tranquillity.

The king of Corea is absolute master of all the wealth of his subjects, to all of whom he is universal heir, and the land is distributed among the people in proportion to the size of their respective families, paying tribute in the productions of the soil. Every seventh year, all the males of the several provinces, who are fit to carry arms, are obliged to attend at the capital in succession, doing military duty for two months; so that during this seventh year, the whole male population of the country is in motion and under arms.

On the death of a king of Corea, the emperor of China sends two commissioners of high rank to invest the lineal successor in the dignity of *Que-vang*, or dependent tributary king, who receives the investiture on his knees. On this occasion, the commissioners receive certain regulated presents, together with about 8000 taels in money. After this, the new king sends an ambassador to do homage to the emperor of China, by knocking his forehead on the ground in the imperial presence; and by this person the regulated tribute is conveyed to the treasury; which last ceremony is annually repeated. Even the consort of the king of Corea must not assume the title of queen, till formally permitted by the emperor of China. All the ceremonies and tributes connected with this dependence are so exactly regulated, that no disputes ever arise, and Corea is said to enjoy a perpetual exemption from external and domestic war. See Du Halde and Grosier, *Descriptions of China;* and the *Voyage of Perouse.* (W. K.)

COREGIO. See CORREGIO.

COREOPSIS, a genus of plants of the class Syngenesia, and order Polygamia Frustranea. See BOTANY, p. 307.

CORFU, an island greatly celebrated in ancient and modern history, lies at the mouth of the Adriatic, in 37° 48′ north latitude; and is separated from the mainland of Albania by a strait only two leagues in width, called the Corfu channel, running from north-east to south-west, and obstructed by numerous shoals.

This is a very fine and salubrious island, nearly of a triangular figure, and about 120 miles in circuit. Its greatest length, from Cape Bianco on the south-east, to Cape Sidero on the north-west, is 60 miles, and the greatest breadth, from Cape Palacrum on the east to Cape Barbaro on the west is about 30 miles.

The climate is mild, but exceedingly liable to sudden transitions from heat to cold, which renders it necessary for the inhabitants constantly to defend themselves by such a quantity of clothing as produces a slight and uninterrupted perspiration. These changes arise from the predominant winds, which either passing over the snowy mountains of Epirus on the east, chill the atmosphere, or blowing hot and sultry from the south, arrive charged with fogs. In common with the surrounding countries, Corfu is subject to earthquakes, which are seldom so violent as to occasion much damage. The shocks are said to be always from north-west to south-east; and at different times, buildings have been thrown down. The surface of the island is hilly, with a few patches or plains of level ground interspersed; and the waters which traverse it, are in general inconsiderable streams.

Of late, a small seam of coal has been found in the island, a discovery of the greatest importance, as most of the fuel was brought from the neighbouring continent. Sulphur, of which no other use is made than to kindle fires, occurs in a hill, and near to it is a copious mineral spring, in the middle of a plain, which is resorted to by the inhabitants in the vicinity. Its efficacy proves most sensible, when immediately taken as it flows. There is a quarry of grey marble in the north part of the island, two leagues inland, which, after being long abandoned, was at length worked by an individual, who exported some to Naples. However, this trade was scarcely begun, when the Venetian government took possession of it, and it has been since turned to no account.

Corfu is scantily provided with wood, and what is required for mechanical purposes, is brought from Albania or Venice. Olives, vines, and a few fruit trees, cultivated around the houses, and some oaks and elms, rarely scattered, constitute the whole. From the want of shelter, there is a proportional scarcity of game: birds of passage do not resort to it in equal numbers as to some of the other islands, and when they do come, it is chiefly to shun the cold of Epirus. Wild swans, coots, and other aquatic fowls are abundant, owing to the marshy grounds on the coast: and fish is also plentiful in the surrounding seas. Corfu has, therefore, few sources to maintain a numerous population, as, independent of goats, apparently indigenous, from the milk of which a quantity of cheese is made, all quadrupeds, either for draught, for the saddle, or for subsistence, are brought from the continent.

The total population of the island amounts to 60,000 persons, dispersed in the town of Corfu and 85 villages. About 12,000 dwell in the town, and the villages contain from 150 to 2000 each, besides those in detached cottages and hamlets. It is probable that the population is decreasing, from the want of encouragement to commerce, and the unsettled government of all the Ionian islands. We know that it anciently was an independent power, which could send out fleets and armies, and whose alliance was courted by other states. At present, its political division is into four provinces, of which the largest, called Mezzo, is situated in the center of the island, and the other three, Lefehimo, Agiru, and Oros, lie to the west, east, and north.

Compared with the natural advantages possessed by Corfu, neither agriculture nor commerce are sufficiently extended among its inhabitants, the principal causes of which arise from their invincible repugnance to labour, and, until lately, from the ill judged restraints of the Venetian government. Other sources have been found in the poverty of the peasant; and the territorial property of the island being vested in a few individuals, who, wanting capital themselves, are obliged to obtain it at a great premium, while they have an uncertain return; the surface also, though susceptible of improvement, is not peculiarly adapted either for the plough or the pasturage of heavy cattle. Wheat is chiefly cultivated, which is of excellent quality, and produced in the proportion of seven to one; but the whole that is raised does not exceed two months consumption of the island, and therefore a supply for the other ten months is required. The wealth of Corfu may be said to consist almost solely in olives, and this, in a great measure, from the encouragement long ago held out by the Venetians, who promised a specific reward for the plantation of each tree. The island was soon after entirely covered with olives, and their propagation is still continued; so that, though destitute of woods, numerous copses every where appear. There are now three millions of olive trees on the island, of four different species, the *mirtades*, *glicoglieydes*, *codiglyes*, and *yenoglies*, which last are the most common. The second species produces two kinds of olives, and those of the third, being the largest, are reserved for salting. There are 1080 oil mills, or presses, and the inhabitants are enabled to export annually 300,000 jars, each containing 33 pounds of oil, of a yellow colour, and thick consistence, which, in respect of quality, ranks the fourth in European commerce. The olive tree produces fruit only once in two years; but circumstances are so favourable to its cultivation, that the product of oil might be doubled or even tripled. From a defect of hands necessary to be employed, according to the most approved modes of culture, the inhabitants plead that they are obliged to await the course of nature, instead of seizing those opportunities which might be converted to the best advantage. The mode of extracting the oil is equally imperfect as the treatment of the plant.

A small quantity of wine is likewise made in Corfu, of a deep red colour, and very strong. Principally from mismanagement, and neglect of the vines, the whole does not exceed four months consumpt of the island, which leaves 30,000 casks of 136 pounds each to be imported for use. The care of the vines is superseded by the attention bestowed on the olives, and, as if they were plants of the same nature, both are cultivated but once in two years. When preparing the ground for olives, vines are planted as a secondary object along with them, and when the period of greatest maturity approaches, it commonly becomes necessary to root them out, that the others may be preserved.

In ancient authors we have glowing descriptions of the beautiful gardens of this island, but at present no remains of them are to be found, and horticulture is in as degraded a state as the cultivation of those plants on which the subsistence of mankind materially depends.

A quantity of salt, sufficient for exportation, is procured from three different places, Eftimo, Castrades, and Potamos. It is carried to Albania, from not being so fine as to render it acceptable in Italy; and even in Albania it bears a lower price than what is imported from other places. Gall nuts, and liqueurs in small quantities, are the only other exports from Corfu. All the oil is carried to Venice; the other commodities to Leghorn, Trieste, Ancona, and Constantinople.

It is universally admitted that the island is susceptible of great improvement, and in the hands of a liberal and enlightened government might more than support itself; but instead of being profitable, it proved extremely expensive to the Venetians. The territorial owners of the island, independent of being indebted to the advances of the Jews established in Corfu for enabling them to carry on their agricultural operations, were under the necessity of dealing with commercial connections of the same Jews established in Venice, for the disposal of the produce. Thus they could not be said to have all the advantages of free trade in exporting their staple commodity, burdened with such restriction by the mother country.

The imports to Corfu are equivalent to at least seven months consumption of the year. The inhabitants are totally dependent on other countries for all the larger quadrupeds, for a large supply of grain, and many articles of wearing apparel. Grain from the Morea and Romelia forms the principal import; besides which, 600 horses, 7000 cattle, and 10,000 sheep and calves, are annually brought from the same quarter. Salt fish is imported, in time of peace, from England, Holland, Leghorn, and Genoa; wine from Dalmatia or the Archipelago, woollen and cotton cloths from Trieste and Smyrna, Indian goods from Constantinople. Turkey gains chiefly by the trade of Corfu; nevertheless, the total balance is in favour of the island, as the value of the exports exceeds that of the imports by about one-twelfth.

Almost the whole trade is carried on in foreign bottoms, for the only vessels lately belonging to it were two or three barks, of above 300 tons each, and a few galliots, which visited the neighbouring islands. The inhabitants have so few products of industry to offer to other countries, that it cannot be expected they will soon require additional shipping.

The island is provided with three harbours, or rather roadsteads. That of Gouin, about two leagues from the town of Corfu, is the best, consisting of a bay a mile in diameter, completely land-locked, and with deep water close to the shore. Small quantities of naval stores were always kept in an arsenal there in the time of the Venetians; and, in order to facilitate the communication with Corfu, a rail-way was constructed in the year 1790. The situation is reputed unhealthy, from the neighbourhood of stagnant marshes and salt pits.

The town of Corfu stands on a rock projecting into the sea, and, from the fortifications guarding it, is a place of strength. However, it is commanded from within by a height, called Mount Abraham; but from the sea it is of difficult access, the entrance to the road-stead before it, being protected by two forts, situated on two elevated rocks, and lined by strong batteries. This island being the most important of all the Venetian possessions during several centuries, and having since been a subject of keen contest among the present belligerent powers of Europe, is fortified with more than ordinary care.

About 12,000 inhabitants, half Greeks and half Venetians, dwell in the town, to which may be added the foreign troops by which the island is now occupied. It contains a naval and military hospital, barracks for a number of men, and powder magazines. By an accidental explosion of one of those in the fortifications towards the earlier part of the eighteenth century, not less than 2000 persons were killed and wounded; and by a similar catastrophe in 1789, 600 individuals lost their lives, four galleys and several barks were sunk in the harbour, and many houses in the town severely damaged. The fortresses are completely mined below, and the roads to the gates of some of them are narrow and precipitous.

As the town was the seat of government, it contains a palace for accommodating the proveditore, or governor-general, when the Venetians held it; an archiepiscopal palace, a cathedral, several monasteries, as also a theatre for the amusement of the inhabitants. It appears, that it originally consisted of buildings within a fortress, which guarded a village; and now its suburbs consist of two villages, Manduchio, and Castrades or Castrati, whose inhabitants are of an opposite character. Those of the one follow fishing or commercial employments, while those of the other are prone to piracy and assassination. Pistols and a dagger are commonly part of their costume.

To avert the dreadful ravages of the plague, the islanders have erected a lazaretto in an eligible situation; and we are informed by an eye-witness, of the precautions adopted to prevent the dissemination of that destructive malady. "The government having obtained information, by the declaration of the lieutenant, that a Venetian vessel had arrived with the plague from Alexandria, of which the captain and a sailor had died on the passage, dispatched a galley to intercept all communication with the shore. Some days after, the crew, with their whole effects, were carried to the lazaretto, where shirts impregnated with tar were substituted for their own clothes, and they bathed twice daily in presence of the health officers. Four nevertheless died, whose bodies were thrown into a deep pit dug by their comrades, and covered with quick-lime, while every thing pertaining to them was burnt. The vessel, after having been completely unloaded, was sunk during twenty days, and then being weighed, no person was permitted to go on board during eight days longer. The crew were now embarked, and five galley-slaves were allowed to join them in place of those deceased. They sailed for Venice under convoy of a frigate, which never lost sight of them until arriving at that port, where they had to undergo a new quarantine for eighty-two days more." By such rigid precautions, the plague is seldom introduced into the island.

From what has before been said, it might be supposed, that the Corfiotes are a rude and impoverished people. But it is by no means so, for a large portion of them are in a state of refinement little inferior to that part of the European continent on which they are dependent, and comfortable subsistence is enjoyed by most of the others.

The mass of the public, for want of seminaries, receive no instruction to improve their youth; and the education of women, excepting what is slenderly bestowed in convents, is altogether neglected. Law and physic were lately held in greater repute; and those who professed them, gained their knowledge at the Italian universities. Learned men, however, have appeared in the island: Collections of manuscripts have been formed in the town, and likewise of antiques, and other matters of curiosity. An academy for the illustration of scientific and literary subjects, was founded here in the seventeenth century; which had but a transient subsistence. Many of the clergy, particularly of the lower orders, are in such a deplorable state of ignorance, that it is said they can scarcely write or read; and in the recitation of prayers learned by rote, they will use as an invocation for rain, that which is designed to implore restoration of the serenity of the heavens.

The ecclesiastical establishment is of a mixed nature, being partly according to the Greek, and partly according to the Roman Catholic rites. The latter were followed by the members of the government, and the military and marine forces, under the Venetians. An archbishop named by the senate was appointed by the pope, and, on his arrival, was received with both ecclesiastical and military honours. In ceremonious entertainments he was served on gold. This establishment comprises the cathedral, two churches, a chapel, and three convents of the order of St Francis.

The greater part of the population follow the Greek church, at the head of which is a protopapa, or chief priest, chosen by an assembly of the clergy and noblesse. He is always of a noble family, distinguished from the chief priests of the other Ionian islands by the title of great protopapa, and is invested with episcopal powers. This place is obtained by the candidate and his friends using private interest with the electors; and bribes are sometimes not unsuccessfully employed on the occasion. Immediately on election, the protopapa gives an elegant and expensive entertainment to the higher order of islanders, who do not scruple, after satisfying their appetite, to carry away part of the feast; pieces of money are thrown to the populace, and a tumult of rejoicing prevails. A cathedral, several churches, and some convents, both of monks and nuns, are under the rule of the protopapa. He remains five years in office, and then returns to the ordinary class of papas, retaining nothing but some slight external decorations as a badge of his former greatness.

Among the manners of the Corfiotes, we find some remarkable instances of weakness and superstition; indeed, the most prominent features of their character are vanity and credulity. One principal source of the revenues of the Greek church arises from excommunications. Any individual may, on the slightest pretext, obtain the excommunication of his neighbour, who is thenceforward utterly excluded from the

Corfu.

protection and privileges of the church—a punishment equally dreaded as the severest corporal pain. Should the protopapa receive a sufficient pecuniary inducement, he will himself pronounce the anathema, by repairing before the house of the person at the head of his clergy, all habited in black, and preceded by a great crucifix with a black flag. The object of vengeance, however, can render the excommunication altogether nugatory, and be restored against its effects by obtaining a counter-excommunication, which is attended with no difficulty, and the same priest is wont to be alike zealous in the service of both. But the ceremony being expensive, the denounced sometimes retaliates by assassinating his enemy. Availing themselves of such an engine, the Venetian government has been known to obtain the excommunication of whole villages, where it was impolitic to use a military force; all intercourse between the inhabitants and their neighbours was by that means cut off, and they were soon glad to testify their submission. The people at large witness these excommunications with uncommon awe: they firmly believe that the earth trembles at the moment the anathema is pronounced, and they utter loud cries of terror.

Marriage in Corfu are celebrated according to the Greek ritual, and attended with various allegorical ceremonies. A table is prepared in the best apartment, on which the Bible is laid between two wax tapers; there is also on a salver at one side, a glass or small phial of wine and a little bread; and on another salver, at the opposite side, garlands of rose-coloured ribbands. When the ceremony is finished, a crown is made by interlacing the two tapers, which is placed above the nuptial bed, to figure the union perpetually to subsist between the spouses. The wife, by established custom, is then seen dissolved in tears, to testify her regret at quitting the virgin state. But the husband has to dread the malevolence of those who envy his approaching felicity; and if, at the moment of consent, any byestander shall cast three knots on a cord and throw it in the fire, it is confidently believed that he will thenceforward be completely enervated. This species of incantation, by knotting a cord, has been known even in our own country; and records, not of a very ancient date, preserve the confessions of some unhappy wretches condemned to the flames, acknowledging its purport in the most unequivocal language. However, it is not void of remedy in Corfu, for the husband, by placing a pistol, which has served for several assassinations, under his pillow, will break the charm. Should he not be completely satisfied of his wife's integrity before the marriage, he can return her to her relations, which is the greatest misfortune to which she can be exposed, as she thereby loses all consideration among her companions.

Unlike that reluctance to part with a favoured object which is felt over all the world, preparations for interment are instantly made when a person expires in Corfu, and two hours scarcely elapse before the body is committed to the earth. Meantime it is clothed in the best apparel which it wore during life, and enveloped in such a way as to leave nothing but the head and hands exposed. Thus clothed, it is laid on tressels covered with a crimson carpet, with a cushion under the head, and a crucifix between the hands: and if the person was unmarried, the body is crowned with artificial flowers. Great lamentations follow, in the course of which are heard eulogiums on the deceased, intermingled with regrets for hisl oss; the body is next carried forth to the church, where the religious part of the ceremony is performed. When this is finished, all the friends kiss the deceased, at the same time uttering something in a low whisper; and it is thought a mark of great respect to a stranger, which he cannot easily refuse, to invite him to pay the like tribute of regard. The dead are interred within the churches, excepting those of the lowest order, who are deposited in a small adjoining cemetery. Every three months, wine, oil, and bread, are brought to the grave, and the deceased is called on, with loud lamentations, to partake of the repast, in which the priests officiating in the church are accustomed to devour when there is no hazard of detection. Mourning consists of apparel universally black, which is extended even to the linen, and all care of their person is entirely neglected. For the nearest relations it continues a year; and sometimes, by a disgusting practice, the linen is never changed during the whole period.

From the change of masters which Corfu has so repeatedly undergone of late, it is unnecessary for us to detail the forms of government that have prevailed. But we may observe, that this being reckoned the principal of the Venetian islands, to which all the others were held subordinate, it was provided with a governor, or *proveditore generalé*; who was frequently a senator. He was assisted by several other persons, some appointed by the senate, others by himself; and his nomination commonly took place a year before his predecessor went out of office. Much state was attached to the situation, and the proveditore annually gave entertainments of ceremony to the clergy, the Venetian noblesse, the military, the Corfiote noblesse, and the commons. By a strange fashion, these entertainments, amidst the appearance of splendour, were a source of profit, for the islanders made abundant supplies for them; and of many present, each according to custom, adroitly slipped an *oil draught* under his own plate. By this the donor drew on himself for a certain quantity of oil from the first harvest, payable either in kind or by an equivalent in money. All the draughts were collected by an aide-de-camp, and put into the hands of the proveditore, who entrusted one of the nobles of the country with levying the amount on becoming due. The proveditore every year made a voyage among the other islands, purposely to examine what contributions could be obtained from them. His secretary took charge of the inquisitorial proceedings which emanated from this institution at Venice; and he himself, as sovereign administrator of justice, decided on the lives and fortunes of the islanders, though his sentence might be reviewed by different tribunals. Means were too easily found to evade the punishment due to crimes; but when once a culprit was condemned, he was, during twenty-four hours preceding execution, chained to a post in the corner of a chapel. In the middle of it was a large stone table, whither he was conducted to partake of a sumptuous repast, served by the domestics of the governor in their richest livery. The repast finished, he was again put in chains, and remained there until led forth, accompanied by a procession of penitents to punishment.

The inhabitants of Corfu pique themselves on their illustrious descent, and many claim an origin from the ancient Greeks and Romans. There are two kinds of noblesse. One, it appears, could be created by a council of nobles, but not unless the family of some individual had become extinct; the dignity of the other flowed from the Venetian government. In the former case, it was necessary that the elect possessed a certain re-

Corfu.

venue, and that no profession or mechanical pursuit had been exercised by his family for three generations. He passed five years of probation without being admitted to the council, and only after the lapse of ten years did he participate in all the privileges. Each year 150 nobles were chosen from a general assembly of the whole, to constitute a council, from which the subordinate magisterial functionaries requisite in the island should derive their appointments.

There are besides a number of Venetian nobles resident in Corfu, an alliance with whom is highly esteemed by the islanders. It has been a special means of promoting civilization and luxury, for the manners of the parent state are thereby incorporated with the colony. Formerly, the females of the island were kept under the greatest restraint: confined within lofty walls and grated windows, they saw none but their nearest relatives; their subordination to their husbands was absolute; they were employed in menial offices about them, and deemed themselves happy in being admitted to their tables.

The vanity and ostentation of the Corfiotes lead them to spend on their persons what should otherwise be spared for the support of their families; and a citizen, to indulge his love of show on public occasions, will be well content to pass a considerable time in subsequent penury. Possessing few opportunities of bettering their fortunes, such practices cannot fail to prove inimical to domestic comfort.

The amusements of the people are either sacred or profane; for nothing is converted to a greater source of entertainment than religious processions. To these they are peculiarly addicted, and their clergy are not slow in exhibiting what is a powerful method of extending their own influence. The festival of St Spiridion, the tutelar saint of the island, is celebrated with particular pomp: Many days are occupied in preparations for it; and when the shrine borne from the cathedral reaches the fortifications, it is received with a salute of 21 pieces of cannon, and the same honours are paid by the shipping in the roads, amidst the ringing of bells and the repeated discharges of musketry. Contrary to any other example with which we are acquainted, the body of this saint does not belong to the public at large, but is the property of a private family named *Bulgari*, and is the source of considerable wealth. One instance occurs in history, where, instead of a pecuniary dower, the body of St Spiridion was given along with a daughter of the family in marriage.

The night of Holy Thursday is especially devoted to processions: each church and each chapel has its own, and a kind of emulation for excellence prevails among the respective devotees. All unite on an esplanade, the streets are crowded, and the blaze of innumerable tapers rivals the light of day. The resurrection of Lazarus depicted on a flag, is carried about the city on other festivals, by a person dressed in the most grotesque manner, who sings the event in modern Greek verses, and occasionally performs a lively dance to a pipe and tabor. Devotees are permitted to kiss the banner on paying some pieces of money. That the superstitions of the people are very gross, appears from a singular custom practised on the night of Holy Thursday. A number of girls, all named Mary, are employed to make a shirt, which is believed to render the wearer invulnerable. But that it may possess this property in its full extent, it is essential that the number of girls be unequal; that the work be commenced after midnight, and completed before break of day.

Corfu.

Corfu has long possessed a theatre, where at first men were the only performers, and to which none but men resorted; neither were there females among the *dramatis personæ*. Married women were afterwards permitted to share in the amusement, but the boxes devoted to their accommodation were latticed in front, whereby a full view of the scenery was intercepted; a decisive proof of the remnants of eastern jealousy. To shun this inconvenience, they consented to appear masked, but the mask was gradually laid aside, and of late years their attendance is unrestrained. It is a point of etiquette to pay and receive visits in the theatre; and the charge of procuring a suitable company of performers devolved on one of the Venetian generals, who was stiled *Preside del Teatro*. During the carnival, the governor-general and principal Venetian nobles and officers never appeared unmasked; but no islander durst wear the colour adopted for their costume, nay it was the exclusive privilege of the first to use crimson velvet in the furniture of his palace. Multitudes flock from the country to behold the diversified spectacle now exhibited, and to witness the singular and ridiculous disguises displayed on the occasion. The most brilliant part of the show, is a kind of tournament, or running at the ring, resembling what was practised of old, devised or revived by a military officer, about the termination of the sixteenth century, who was killed on the first encounter. One of the broadest streets is prepared for this exercise called *Chiostra Publica*, on each side of which are erected amphitheatres for accommodating the spectators. The competitors appear splendidly attired, and mounted on horses with the richest housings; they first break a lance on a wooden figure, and next try to carry off on its point a small ring suspended across the street. Each horseman follows at full speed in his turn; and the ring must be three times borne away to entitle the victor to the prize. But the nobles alone can contend for it. An inferior description of the same amusement is provided for artizans and merchants, when the victor is accompanied home with the beating of drums.

Corfu has from time immemorial preserved an importance to which its present territorial extent does not seem to entitle it. Some philosophers have conjectured, that convulsions of the globe have reduced its size, by severing its neighbouring dependencies from its shores; and there is much probability that the population was once more numerous. It has been alike famed in mythology and in profane history; and known by the names of Drepanum, Macris, Scheria, Corcyra, and Corfu. Both Horace and Virgil make it the resort of their fabulous heroes, and we know that it received Aristotle, as well as his illustrious pupil, Alexander the Great.

This island was successively subject to the Greeks and Romans; a fact which, independent of written history, is proved by medals and inscriptions frequently discovered. When Italy was over-run by the barbarians, Corfu suffered universal pillage; and under the emperors of the East, participated in the different contests for dominion. At a later period, when Charles King of Naples approached its shores with the design of conquest, the evils of war were averted by voluntary submission. But having thrown off the Neapolitan yoke, it experienced an attack from the Genoese, who succeeded in taking the chief towns, though they were ultimately expelled. However, the apprehensions of the inhabitants were so much excited for a renewal of the attack, that they implored the aid of the Venetians, and in doing so, committed the island to their administration. The Genoese returned, and were again repulsed. A more formidable enemy now appeared in the Turks, who, under the famous Barbarossa, had before unsuccessfully invaded the island. In the beginning of the 18th century, a powerful army, aided by a large train of artillery, invested the capital; but after a brave defence by Count Sculembourg, the commander, they were forced to retire with the loss of 15,000 men and 64 pieces of cannon. The Venetian government shewed their gratitude to this officer, by erecting a white marble statue of him, with an appropriate inscription, during his life; an honour which few have enjoyed.

Some time after the French began to disturb the tranquillity of Europe, they made themselves masters of Corfu, towards the latter end of the last century, and were allowed to retain it by the treaty of Campo Formio in 1797. The fifth article of that treaty declares, that "his majesty the Emperor, King of Hungary and Bohemia, consents that the French republic shall possess in full sovereignty the Venetian islands of the Levant, viz. *Corfu*, Zante, Cephalonia, Santa Maura, Cerigo, and other islands their dependencies; as well as Butrinto, L'Arta, Vonissa, and in general all the former Venetian establishments in Albania, situated lower than the Gulf of Lodrino."

Corfu has ever since been the theatre of warfare: it was taken by the Russians, and then by the French, in whose possession it still remains. Not long ago, a convoy with provisions destined for supplying the garrison, was captured or dispersed by some British ships of war. See Marmora *Istoria di Corfu.* Quirini *Primordia Corcyræ.* Spon et Wheler *Voyage*, tom. i. Olivier *Voyage*, tom. iii. Scrofani *Voyages*, tom. i. iii. (*c*)

CORINTH, was a small dynasty of Greece, bounded on the east by the gulf of Saron; on the south, by the kingdom of Argos; on the west, by Sicyon; and on the north, by the isthmus and bay of Corinth, the latter of which is now called the Golfo de Lepanto. The capital of this territory, which bore the same name with the territory itself, was situated about the middle of the isthmus, at about the distance of sixty stadia from the sea on either side. It is said to have been founded by Sisyphus, the son of Æolus; but, at first, it was denominated Ephyre, an appellation which the ancient annalists derive from a lady of that name, who was the daughter either of Oceanus and Tethys, or of Epimetheus and Myrmex. Corinthus, who, by different authors, is said to be the son of Jupiter, or of Marathon, or of Pelops, afterwards rebuilt and adorned the city, and from him it received the name by which it is chiefly known in ancient history, and has descended to our day. The only other cities of any magnitude, in this country, were Cenchrea, situated on the bay of Saron; and Lecheum, on that of Corinth; and as these possessed excellent harbours, at no great distance from the capital, and having an easy access both to the Ægean and Ionian seas, they became the greatest emporiums of trade of any places in Greece. As the whole region was mountainous and rather barren, the inhabitants were not much addicted to agriculture; but from their local situation, they possessed singular advantages for commerce, which they carried on to a great extent. The natural consequences of an extensive commerce were wealth and luxury: fostered in this manner, the city rose in magnitude and grandeur; and the elegant and magnificent temples, palaces, theatres, and other public buildings, adorned with statues, columns, capitals, and bases, not only rendered it the pride of its inhabitants, and the admiration of strangers, but gave rise to that order of architecture which still bears its name. Besides the citadel, built upon a mountain, which overlooked the city, called Acrocorinthium, the works of art which chiefly displayed the opulence and taste of this people, were, the grottos, raised over the fountain Pyrene, sacred to the muses, and constructed of white marble. The theatre and stadium, built of the same materials, and decorated in the most magnificent manner. The temple of Neptune, containing the chariots of that god, and of Amphitrite, drawn by horses covered over with gold, and adorned with ivory hoofs. The avenue which led to this edifice, decorated on the one side with the statues of those who had been victorious at the Isthmian games, and on the other with rows of tall pine trees. Though the arts of architecture and of sculpture were carried to a great height, yet, in a city abounding with trade and luxury, the sciences did not take a deep root, nor were they enabled to attain maturity. Even the art of war, which their situation, commanding both seas, and separating, by the isthmus, the one half of Greece from the other, gave them great advantages for prosecuting, was never resorted to for purposes of ambition, but only for defence; and it was their wealth more than their valour that gave them any influence amongst their neighbours. But though their genius was not warlike, yet they cultivated peace, not from indolence or pusillanimity, but from a wise estimate of the blessings which it confers; and hence they knew to value and to defend their liberty and independence, which they never yielded either to internal despotism, or to external force; and from amongst them arose some of the foremost candidates for military renown, who not only defended their own territories, but were courted by the neighbouring states to lead their armies to fame and victory. We are sorry to add, that their religion, which was a species of the most licentious idolatry, cherished, instead of checking, the appetites and passions of its votaries; and that the statute which enjoined the temple of Venus to contain a thousand prostitutes, was not the most disgraceful of their civil and religious institutions.

The exploits of Sisyphus, which have descended to our day, like those of all the heroes whom we meet amidst the mists of antiquity, are few and insulated. After laying the foundations of Corinth, his life was disgraced by rapacity and debauchery, which however were not so much the vices of the man as of the age. Prompted, at last, by the ambition of extending the boundaries of his dominions, he invaded the territories of Attica, and fell by the hand of Theseus who then governed that kingdom. Nor did the vengeance of heaven pursue him in this world only. On account of his crimes, if we believe the fabulous muse of Greece, Sisyphus is doomed, in hell, to roll a large stone to the top of a mountain, which, when it has reached the summit, bounds backward with accelerated impetuosity, and again invites him to renew his hopeless labour.

He was succeeded by Glaucus, his son, by Merope the daughter of Atlas. This prince, whom Euripides calls Creon, received, and hospitably entertained Jason and his wife Medea, when expelled from Thessaly by Acastus; but when he gave his daughter Glauce in marriage to the exiled monarch, Medea was so enraged at the perfidy of her husband, that she murdered her children, burnt her palace to the ground, and fled to Athens. It is said, that Glaucus, to increase the swiftness of his mares, precluded them from all intercourse with the males; and that Venus, enraged at this indignity offered to her authority, inspired the mares with such fury, that they tore their master to pieces when returning from the celebration of some funeral games.

He is said by some to have been succeeded by his son Bellerophon, who received that name from the murder of his brother Beller, for which he was expelled to Argos; but it is more probable that Bellerophon was expelled during the life of his father, and that at his death, Ornytion, a younger son, ascended the throne. From him the sceptre descended through a long line of descendants for upwards of 400 years; but as their names are associated neither with the history nor poetry of Greece, we shall suffer them to remain unnoticed. It is said by some that the last of the race died childless; but by others, that the supreme power came into the hands of two brothers, Doridas and Hyanthidas, who were forced to resign the sovereignty by Aletes, one of the descendants of Hercules, who ascended the throne. The kings of the same family who succeeded him, proud of their origin from that hero, called themselves Heraclidæ, to the fifth generation; when Bacchis ascending the throne, changed the family name, of which his ancestors boasted, into that of Bacchiadæ, derived from his own, and under that appellation his posterity swayed the sceptre of Corinth for about 400 years. From Archias, one of these kings, Syracuse the metropolis of Sicily derived its origin; and about the same period, in order to carry on their commerce with distant countries, the Corinthians invented those ships which, from their peculiar construction, were called *triremes*.

Telestes, the last of the family of the Bacchiadæ, was only in his infancy when his father Aristomedes died. His uncle, Agemon, who at first governed the kingdom in the name of his nephew, soon usurped the sovereign power which he exercised during sixteen years. He was succeeded by his son Alexander, who, after reigning 26 years, was killed by Telestes, who at that period asserted his right to the crown, and succeeded in the enterprise. He, however, abused the power which his valour had gained; and in the twelfth year of his reign he was deprived of his life by two of his own kindred.

At his death, 200 of the principal Bacchiadæ assumed the government, which now became aristocratical, united under one of their own body, whom they chose as president, and who bore the name of Prytanis. In this manner was Corinth governed for about 240 years, when Cypselus, one of the Bacchiadæ, prompted by the response of an oracle, formed the ambitious design of subverting the power of the aristocracy, and placing himself upon the throne. His wisdom and valour accomplished his design, and having reigned thirty years, he died and resigned the sceptre into the hand of his son Periander. This prince, at the beginning of his reign, gained the affection of his subjects by his moderation and justice; but forgetting the virtue and happiness which he then practised and enjoyed, he became by degrees a tyrant, equally an enemy to the peace of his family, and the prosperity of his kingdom. After having murdered many of the nobles of Corinth, committed incest with his own mother, put to death his wife Melissa, and banished his son Lycophron for weeping over the ruins of his family, he died, and, by the meanness and ignorance of a barbarous age, was enrolled amongst the seven sages of Greece, because in the midst of his cruelties and debaucheries, he had paid some attention to learning and its votaries.

We should willingly have adverted to some of the memorable revolutions which afterwards happened to this country, but as the limits prescribed to us will not admit of it, and as, from this period, the history of Corinth becomes identified with the history of Greece, of which it may now be considered as a province, we must refer our readers to that article for an unbroken narration of its future history. CORK, a well known substance in very general use, is the exterior bark of a tree of the oak genus, the *Quercus Suber* of botanists, which is indigenous in the southern parts of Europe and Asia Minor, and is abundant in the south of France, Spain, Portugal, and Italy. The cork trees are fit to be stripped of their exterior bark at fifteen years old; but, while young, this operation ought not to be repeated till after an interval of three years. Older trees may be safely barked for eight successive years, and should then be allowed to rest for two or three years. If not stripped artificially, this outer cork-bark splits and peels off naturally, in consequence of a new growth forming annually under that of the preceding year. The quality of this useful substance improves with the age of the tree.

It is taken off in sheets or tables of considerable size, from the entire stem or body of the tree; being cut circularly at top and bottom, and also perpendicularly in portions of convenient size, and then peeled off by means of a knife, resembling a hay spade, and similarly used. Or, after the circular and perpendicular incisions are made, which cut off the connection of the cork from being nourished by the parent tree, it is left for some time to loosen from the under bark, when its separation is easily effected by the hand. After its separation from the tree, the Portuguese, who chiefly supply Britain with this commodity, prepare it for sale by reducing its cylindrical curvature nearly to a flat in the following manner. It is piled up in ponds or ditches, with the hollow side undermost, and loaded heavily with stones; and this operation is afterwards more completely effected in a damp cellar, by which means it becomes nearly flat. This is called *laying* the cork; and it is afterwards dried completely over a strong fire, which operation is called *burning* the cork. Some persons satisfy themselves with this single operation, in which the convex side of the cork is laid to the fire, and continued over it till it becomes flat. From negligence in this process, the article often receives too much heat, which gives the blackness so frequently seen in articles made of cork. When sufficiently flattened, by being *burnt* or roasted rather on its back, the other side also is subjected to the operation of the fire, so that both surfaces are partially charred: and though this operation is sometimes carried too far by the Portuguese, it is also sometimes not sufficiently performed, as our cork-cutters have often to repeat it in this country before it is fit for their use. During this operation of burning, the Portuguese peasants are careful to cover up all holes or crevices, by the artful introduction of soot and dirt. Be-

Cork. sides flattening the pieces of bark, this operation closes up the pores of the cork, by occasioning it to contract, and greatly lessens its sponginess and open texture, which would otherwise render it a filter, especially in what are called taps and bungs, which are cut perpendicularly to the natural surfaces. After the operation of burning, the cork is built up into stacks, till purchased by the merchants or their agents for exportation.

The principal use of cork in the present day is for making stoppers to bottles that are to contain liquids which are not of a corrosive nature; for which purpose it serves admirably, as it is easily compressed by pressure, expands readily by its elasticity, fills and stops very closely the space into which it has been forced, does not communicate any disagreeable taste or flavour to the liquors which it retains, and does not allow any watery or vinous liquor to escape. This substance is also used as *taps* and *bungs* for casks, is made into inner soles for shoes, floats for fishing nets, artificial legs and arms for those who have suffered amputation, and a variety of other useful articles. It is also used in the construction of Mr Greathead's boat, for preserving the lives of seamen in danger of perishing by shipwreck,—a late admirable invention, for a particular account of which see LIFE-BOAT. Owing to its elasticity, it is also used for many other useful purposes, such as the spring of the lifter in ordinary candlesticks, and has been recommended as a good substitute for weights and pulleys for holding up light window-sashes. Cork is also used in Spain and Portugal for lining stone-walls in particular places, rendering the apartments very warm and dry; and is also employed for lining the sides of ships of war, to prevent splinters in time of action. Besides these uses of cork, it is made into what are called *cork jackets*, for preserving the lives of persons in danger of drowning. For this purpose, pieces of cork, about three inches long and two wide, and the entire thickness of the bark, are inclosed between two pieces of strong linen or canvas, made in form of a jacket without sleeves, and sewed round each piece to keep them all in their proper places, the lower edge of the jacket, about the hips, being left in loose flaps, like the under part of stays, to leave freedom to the thighs in swimming.

This substance, as imported, is seldom sufficiently flattened or dried for being used by our cork-cutters, who accordingly have to render the process of *laying*, or *burning* rather, more complete, by roasting it again over a fire, which is generally made of cork shavings or cuttings, under a sparred iron frame standing on four legs of convenient height. In this new operation, the convex side of the slips are laid next the flame, when the heat counteracts the natural bend, and reduces the cork to sufficient flatness, while at the same time it renders the substance more compact, and sufficiently dry to admit of being easily and accurately cut. It is afterwards cut into narrow or wide slips, according to the particular purposes for which it is to be applied, as corks, bungs or taps, and these slips are afterwards cut into squares, proportional to the uses they are intended for. The squares intended for corks, are sorted into three denominations, *short*, *short-long*, and *full-long*; and, as the bark is not of the same quality throughout each piece, the finished corks are finally sorted by a boy into four kinds, *superfine* or *velvets*, *fine*, *common*, and *coarse*, and are sold at proportional prices. The only tool used by the cork-cutter in forming the corks, is a broad, thin, and sharp-edged knife, with which he adroitly pares the squares into cylinders, or rather slightly tapering frustums of cones, after which he pares off the top and bottom quite level, and throws the finished cork into boxes or baskets for receiving corks of the same length. The parings are saved, to be afterwards sold to colour-makers, for being charred into what is called Spanish black.

Some other productions of the vegetable kingdom have also been occasionally used for similar purposes, as possessing properties similar to those of cork; such as the exterior bark of the *Spondias lutea*, Mombin, or Jamaica plum, which is sometimes brought over as a substitute for cork. The bark also of a North American tree called Myssa, has been applied to similar purposes. Liquorice roots are sometimes also used in the same manner.

Cork was certainly known to the Greeks, under the name of Φελλὸς, and Theophrastus describes the tree as a species of oak having a thick fleshy bark, that requires to be stripped off once in three years, to prevent it from perishing. He mentions also its great levity, so as never to sink in water, from which quality it might be applied to a variety of useful purposes. The *Suber* also of the Romans was evidently the same substance with our cork, as Pliny describes it in the same terms used by Theophrastus respecting φελλὸς. It was applied by the Romans to many useful purposes; particularly as floats for nets, and as buoys for anchors, under the name of *anchoralia*. They also employed it for soles to their shoes or sandals, to keep their feet dry, and for making their ladies appear taller. Pliny also mentions its use for stopping vessels of all kinds; but its more universal employment for bottles is entirely of modern invention, as glass bottles do not appear to have been introduced, at least into general use, before the fifteenth century. The ancient Egyptians also employed cork in the construction of coffins, which were coated within with a resinous substance. The use of cork, for enabling persons to swim, and to preserve from drowning, was very early known to the Romans; as the messenger sent by Camillus to the capital, when besieged by the Gauls, took cork with him under his light garments, to enable him to swim across the Tiber with safety.

The bark and acorn of the cork tree, charred and reduced to fine powder, have both been considered as astringents, externally applied, but are probably mere inert charcoal. Cups made of cork have even been recommended for the use of hectic persons. The chemical properties of cork have been already treated under the article CHEMISTRY. (W. K.)

CORK, a county of Ireland, situated in the province of Munster. It is bounded by the county of Waterford on the east; that of Kerry on the west; those of Limerick and Tipperary on the north; and by the Atlantic Ocean on the south. Both in extent and population it is by far the largest in the island, containing in these respects, according to Dr Beaufort, about a tenth part of the whole

Boundaries.

This county affords great abundance and variety of scenery. With an extensive range of bold and rugged sea-coast—some large rivers, and many smaller streams—mountains and hills of various height and aspect—plantations of thriving wood—corn fields, and walks of sheep and cattle—towns, villages, and hamlets—and a multitude of family seats, belonging to noblemen and gentlemen of fortune—it offers to the traveller's eye every diversity of grand and beautiful, of rich and barren, prospect. Indeed, some parts of it, particularly Glengariff, in the

Scenery.

Cork.

neighbourhood of Bantry Bay, are said to possess so much of the romantic, the pleasing, and the sublime, as to rival Killarney itself, which is usually and justly celebrated as one of the finest spots in the united empire. Mr Wakefield recommends this part of Ireland, in the language of enthusiasm, to the attention of every one who seeks for nature in her most favoured retreats.

Water-fall.

At Hungry-hill, not far from Ross-Mac-Owen, there is one of the finest water-falls in Europe. Hungry-hill is a high, rocky, and almost perpendicular mountain, not less than 2000 feet above the level of the sea, on the top of which a large lake is collected from several small rivulets and springs. The water falls from that height in a sheet at least thirty feet broad, which grows wider as it descends. When half-way down, it dashes on a projecting rock, raising a mist which covers almost a third part of the hill, and which, in certain circumstances, exhibits the phenomena of the rainbow. It afterwards falls from rock to rock, till it has passed the more rugged declivities of the mountain; and before it reaches the ocean, it falls over a lower hill, in the form of a beautiful arched cascade. There being very little water here during the summer months, this fall is seen to most advantage in winter and in rainy seasons.

Climate.

The climate of this county is mild and favourable. It is exempted from the extremes of heat and cold. Cattle, in general, are never housed, even on the mountains, and yet thrive well. Geraniums, myrtles, and exotics of every kind, may remain out of doors the whole year, without suffering injury, provided they be placed in a southern aspect, and screened from the cold northerly and easterly winds by some bank or rock. In more sheltered situations, the deciduous trees are stripped of their foliage only for a very short time. Wet weather is prevalent in the south-west parts of the county. But as the sub-stratum of the soil is in general dry, the moisture is seldom more than sufficient to carry on the vegetation. From a regular diary of the weather, kept for several years in the city of Cork, it appears that the wind blows from the south to the north-west, at least three-fourths of the year. In the course of thirteen years, the barometer had ascended once to 30.4 inches, and in that time its lowest height was 28.2. The average quantity of rain, which fell from the year 1738 to the year 1748 inclusive, was 38.26 inches. The mean temperature in different parts of the city, in 1788, was from 52° 5′ to 53° 5′, which was about 2° higher than it was in Dublin during the same year, and about 4° higher than in Londonderry. The mean temperature, in that year, of the coast to the south of the city of Cork, as observed by means of deep covered wells, in limestone and other soils, was 51° 2′. Mr Wakefield was at Glengariff, west of Bantry, in the last week of October 1808, and, at that late season, he found the temperature as mild as it is in England in the first week of June.

Agriculture.

On the agricultural state of Cork much praise cannot be bestowed. It enjoys many advantages, both of soil and climate, and maritime situation; but these are sadly counteracted by other circumstances of a most unfavourable kind. Independently of that general depression under which the people labour, and which must always be hostile to improvement of every kind, there is here a very imperfect system of husbandry, immediately proceeding, no doubt, from the want of skill and capital on the part of the farmers, but as certainly perpetuated by a want of that exertion and liberality which, in such a case, should be displayed on the part of the landholders. The evil must be traced, also, in a great measure, to the practice so prevalent in Ireland, of the great proprietors going to distant places to spend their time and fortune; thus withdrawing that personal influence which might be so useful at home, where it is so much needed, and leaving their tenants to be oppressed, and their estates to be mismanaged in their absence. From this injurious treatment, Cork is by no means exempted, though, at the same time, it must be observed, that in few counties are there to be found such a proportion of respectable residents. Amidst all these discouragements, however, the agriculture of this county has made considerable progress in some districts; it is still advancing, though by very slow degrees; and were the obstructions and difficulties, with which it has still to struggle, effectually removed, there are few places where it could proceed with a more rapid pace, or with more certain success. A Farmer's Society has been established at Cork, and gives premiums for the best ploughs, oxen, pigs, &c.

Aspect.

The county is in general hilly. Very little of it can with propriety be called flat, and the whole of the south-west part is formed by a ridge of mountains, which rises to a considerable height, and extends into the sea. Most of its western side is rough and uneven, but not so much so as to prevent it from being subjected to the plough.

Soil.

It contains great tracts of poor and barren land, particularly in the barony of Ban and Bantry, and in the western parts of Carbery and Muskerry, in which the Sheely mountains are situated. A great proportion of the mountainous land is either naturally so wretched in soil, or has been so little attended to, where it is susceptible of improvement, that it is not, in fact, worth threepence an acre. And even the flat hills, which are situated at a distance from towns, bring a very low rent. Those, indeed, which are in the neighbourhood of large towns, are more valuable. Some of them are cultivated almost to the summit, and are tolerably productive. But they form only a small proportion of the whole, one part of which is absolutely sterile, and the other almost wholly neglected. At the same time, there are not wanting individuals, who have done much to bring the latter into as productive a state as possible. Of these attempts, a gratifying account is given by Mr Townsend. The good land in this county, however, predominates; and while, in many places, its quality is excellent, in some also it has been brought to a high pitch of cultivation. This is to be seen especially in the vicinity of the Blackwater, and in the barony of Innskilly. The south-west and northern parts have been much neglected; they are however very capable of improvement.

Crops.

In the southern districts a great quantity of different kinds of grain is produced on the whole; though the individual quantities are small, in consequence of the land being much divided. In Donneraile, and other places, a considerable quantity of wheat is raised, but the crops are seldom or never abundant. Indeed Mr Townsend, in his Survey, makes this general remark, that the acreable wheat produce of the county is not great. To the south of Cork city this grain forms a regular part of the rotation of crops—a circumstance by no means common, and which was introduced there by the failure of the potatoe crop in 1800. Barley is cultivated nearly in the same proportion as wheat, each occupying the land occasionally as the farmer happens to be influenced by the respective price of each. The demand for this grain

Cork.

comes chiefly from the breweries and distilleries in the city of Cork, and partly from the breweries in Bandon and Cloghnikilty. There is also to be found here and there a field of bere, or bear, affording a pretty good return. Oats are sufficiently common. About 40 or 50 acres are cropped with hemp. This crop is usually good and lucrative, not so much so, however, as flax, of which considerably more than 1200 tons are annually raised. In the year 1809 there were sown with flax about 1462 acres, out of which it is supposed that 4481 bushels of seed would be saved, besides giving 43,860 stones of flax, at 10s. 6d. per stone. Clover is seldom cultivated by common farmers, excepting on a small scale, and in inconsiderable quantities; indeed it is stated by Mr Newenham, that not more than 5000 acres are sown with this grass throughout the whole island. Potatoes are every where raised by the farmers in abundance, engrossing almost the whole of their manure, as well as of their labour In Doleraine, potatoe land lets as high as six guineas an acre. One preparation for this crop is very commonly paring and burning, especially on the coarser lands, where it is considered as the most expeditious mode of reclaiming waste ground; and it is practised in spite of the legal enactments against it, and the unwillingness of landlords to permit it. In some places turnips are sown, and used as food for sheep as well as cows.

The following Table affords a view of the average quantities of seed used, and of the produce, per English acre, in the southern districts of the county, from which the general state of agriculture there may be ascertained with some accuracy. The average is taken from different years and different estates.

Crops.	Seed used per Eng. Acre. lib. Avoirdupois.	Produce per Eng. Acre. lib. Avoirdupois.	Proportion between seed and produce.
Wheat	161	1,400	1 to 8.9
Bear	140	2,016	1 to 14
Barley	147	1,993	1 to 13.1
Oats	154	1,671	1 to 10.9
Potatoes	952	12,695	1 to 13.1
Flax	16 pecks per Acre.	1,040	1 p. to 65 lb.

Prices of labour, &c.

The average prices of labour, &c. estimated from returns made by persons in different districts, were, in 1811, as follow:—For a man, per day, 11½d.; a woman 6½d.; a carpenter 2s. 11¾d.; a mason 2s. 9¼d.; slater 3s. 5½d.; quarryman 1s. 8¼d.; a thrasher 1s. 5d.; mason, per perch, 1s. 6d.; slater, per square, 6s. 8d.; bricklayer, per perch, 1s. 3d.; blacksmith, per day, 2s. 5¼d.; labour in harvest of hay or corn, per day, 1s. 11¼d.; day labour of children 6½d.; mowing grass, per acre, 4s. 6¾d.; fencing, per perch, 2s. 3¼d.; for grazing a cow, per week, 2s. 4¼d.; for grazing a horse, per week, 2s. 9d.; a car and horse, per day, 3s. 11¾d.; a saddle horse do, 5s. 7¼d.; a plough, do. 9s. 9¾d.; shoeing a horse 3s. 5¼d.; land-carriage to Dublin, per cwt. 8s. 3¼d.; wheat, per barrel, L. 2 : 5 : 6; barley, per do. L. 2, 5s.; oats, L. 1 : 5 : 8; potatoes, per stone, 4½d.; hay, per ton, L. 5 : 3 : 5; beef, per lb. 6d.; mutton 6½d.; veal 6½d.; pork 4d.; lambs, per score, L. 10 : 2 : 6; eggs, per score, 10d.; undressed flax, per cwt. L. 3 : 17 : 6; wool, per stone, L. 1 : 1 : 3.

Manures.

In the bay of Glengariff, and towards the north-west parts of Bantry Bay, there is an inexhaustible store of coral sand, which is held in the highest esteem, and is much employed in the neighbourhood, as a manure. Large quantities of it are dredged up for that purpose. It is purely calcareous; and its effects are said to be perceptible for twenty years. Sea sand, also, containing a great deal of calcareous particles, is very generally used on the coast. It is usually laid upon the ground just as it is brought from the shore; and not unfrequently it is, in the first instance, put into the farm-yards instead of straw, for the cattle to lie upon, and after being impregnated with their urine, and mixed with their dung, is carried out to the fields. It is said to ameliorate very much the quality of the ground, not only by its operation as an alterative, but also in a mechanical way, by opening and mellowing the soil. A great proportion of the manure in this country, as might be expected from its maritime situation, consists of sea-weed, which is annually cut from the rocks, or gathered in the coves and harbours. It is collected with unceasing diligence, and is principally applied to the potatoe grounds. It is a source of considerable profit to the proprietors on the coast. A small strand at Donoughmore lets for £60 per annum, besides supplying the farm within whose bounds it is situated. Marl abounds in this county. It is a favourite manure, used in great quantities, and attended with proportionate effects. Fossil shells also are found here. Dung and straw manure, on which, in every agricultural country, the farmer chiefly depends, is not an object of much attention with the farmers of Cork, and is made by them in very inconsiderable quantities. In some parts, however, it is not uncommon for people to pound their straw into muck on the high road, and for this purpose to have it always spread in front of the farm-house. The roads being made of limestone, a deal of this is scraped off when the pounded straw is removed, and in this way an excellent manure is produced. The farmers, however, have no proper ideas of the importance of manure, and of the necessity of collecting as much of it as possible. As a proof of their ignorance or their carelessness in this respect, we are informed by Mr Townsend, that they often erect their houses upon the very margin of a public road, in the channel of which a great proportion of the manure is washed away; and that, on the same principle—the principle of a most mistaken economy—they grudge a few perches of ground to the use of a farm yard.

Fences.

Fencing is very imperfectly understood in this county, and still more imperfectly practised. Nothing of the tree kind is admitted, which not only gives an appearance of nakedness to the country, but deprives both the corn and the cattle of that shelter which is so conducive to their growth. The usual fence consists of a bank from 4 to 5 feet broad at bottom, tapering to the top, and rising to the height of 5 or 5½ feet. It is formed sometimes of earth dug up from either side, and sometimes it is composed chiefly of stones. This is too often allowed to remain quite bare. But in general it is covered with furze, which, when well grown, makes a tolerably good hedge;—serving the triple purpose of a fence to the field, winter food for the horses, and fuel for the house.

Implements of husbandry, &c.

Most of the usual implements of husbandry are to be found here, but they are unskilfully constructed and unskilfully managed. The plough in common use is extremely rude and defective; as one proof of which it may be stated, that the coulter and sock are placed so obliquely as to oblige the ploughman to turn it to the left side, in such a manner as to keep the mould-board entirely out of the ground. The plough is drawn very

Cork.

seldom by oxen, frequently by mules, and generally by horses, the usual team of which consists of three, four, and sometimes more, yoked abreast. Occasionally a plough with two horses is to be seen, which requires one man to hold and another to drive. It is a great sign of rudeness in the agriculture of this county, that no common farmer is provided with a roller or a heavy harrow. This is one reason why their fallows are so imperfectly made. The clods are broken by manual labour: and for this purpose a spade is employed. Indeed the spade culture is in very general use. It compensates in some measure for the sparing use of the plough, and may frequently be used with good effect, where the plough could make little or no impression. The preference of the spade, however, is rather the result of habit than the dictate of judgment. Their flail is very inefficient, made of any kind of wood that can be obtained with least trouble, and seldom heavier than a school-boy's whip. Sliding cars are in common use among the poor farmers, though forbidden by act of parliament to be used on the high roads. But the wheeled-car is now introduced into all the better parts of the county, and is said to answer the purpose extremely well. In the mountainous districts, manure is often carried to the fields in panniers. Almost every gentleman, as well as substantial farmer in the county, has regular labourers, whom he pays with what are called conveniences; these consist in a house, ground for potatoes, grass for sheep and cows, &c. Some of the labourers are paid in money. The potatoes are generally digged and collected by Kerry men, who can earn sometimes by this employment about eight shillings per week, besides their board.

Cattle, sheep, &c.

The breed of cattle in this county is rather of an inferior kind. The farmers, not being able to afford a high price for stock, must be contented to buy it of a small size. In the more hilly grounds, stock of this kind may be considered as most advantageous. Among the mountains towards the south-west of the county, a small breed has been produced, by frequent crossing of the Kerry, or native Irish breed, with the long horned. It has very nearly the same character and properties as the former, which is accounted the best. Lord Bantry has introduced the Devonshire cattle, which are said to answer exceedingly well, both in milk and flesh. There is a great number of dairies in this county, each having at an average about 30 or 40 cows. The favourite breed for milk is the half Holderness breed. The common Irish cow frequently equals them in the quantity, and the Devon cow excels both in the quality, of the milk. The city of Cork is the chief market for the butter produced in these dairies. It has been long celebrated for its sweetness. In the mountainous districts, the male native sheep are to be found. These are of a small size, thin in the fore quarters, narrow in the loins, very active, and covered with nearly as much hair as wool. Gentlemen purchase them for their own use. There are almost no large flocks. Very few are fed on turnips; some on potatoes; and a sheep fold is never to be met with. The Leicester breed has been partially introduced. The sheep belonging to the small farmers are long woolled, and very diminutive in size. Some Merino sheep were disposed of a few years ago at Cork, and bought up for breeding, at high prices. There are considerable numbers of goats, which are kept by all the families that are not able to purchase cows. In some places hogs are kept to a great age, and attain a monstrous size. They are fed and fattened on potatoes only, and are allowed to run about all the while. Throughout the neighbourhood of Bantry, Cork, Cove, and Castlemartyr, they are a long-legged, narrow-backed, ill-shaped breed of animals. Turkeys abound in the county; so much so, that an annual fair is held for them.

Condition of the farmers.

The condition of the farmers is not remarkable either for comfort or respectability. None of the farms are large. Most of them are extremely small. Such as exceed 30 acres are often held in partnership by two or more families. This species of tenure is promoted by their common law of inheritance, which divides the land of the father among his sons. The practice of letting the farm to the highest bidder, contributes also to depress the tenant, as well as to sour his temper. Little or nothing is done to stimulate his exertions and to better his situation, by those who are both able and bound to do it; though to this general statement there are several honourable exceptions in the case of resident proprietors, whose conduct to their tenants is equally just and liberal. The cotter tenant, according to the account given by Mr Wakefield, is in a very miserable plight. He has a cabin and a small patch of potatoe land at a low rent. He also agrees for the keep of a *collop* (10 sheep), or half a *collop*, at a rent still lower. At the same time he works for his landlord at 5d. per day; but when he comes to settle, he receives nothing, as the food of his sheep is set off against his charges for labour. In this way he toils without end, while his family eats up the produce of his spot of ground. The lower Irish call this "working for a dead horse," or getting into debt. All the houses of the farmers and tenants, with a very few exceptions, are wretched. Their mode of living is coarse; their manners are barbarous; and on the whole exhibit nothing on which the patriot's eye can rest with satisfaction.

Rental, estates, &c.

The rental of this county has been variously estimated by different individuals. Mr Townsend takes it at 20s. per Irish acre, Mr Newenham about 30s. and Mr Wakefield takes the medium, viz. 25s. From the large proportion of hilly and unproductive land which the county contains, Mr Townsend's valuation is perhaps the most accurate. At that rate, the whole rental will amount to a little more than a million. According to Mr Young, the average rent of an acre in 1777 was 5s. 2d. making the gross rental of the county at that period about L. 250,000. Mr Wakefield has given in his late work on Ireland the annual revenues of some of the leading proprietors of Cork, which it may be interesting to the reader to state. Lord Bandon has L. 30,000; Lord Shannon, Lord Cork, and the Duke of Devonshire, above L. 20,000 each; the heirs of Smith Barry, and Lord Longueville, L. 20,000 each; Sir John Keane, and Lord Egmont, L. 14,000 each; Mr Freeman, L. 15,000; Lord Ponsonby, Mr Newenham of Coolmore, Mr Anderson, and Lord Riversdale, L. 10,000 each; Mr Jephson L. 12,000; Lord Middleton, Mr Hyde, and Colonel Fitzgerald, L. 8000 each; Lord Arden, and the Marquis of Thomond, L. 6000 each. Lord Carbery has 32 miles of sea-coast, and Lord Kenmore has 20,000 acres.

Rivers.

This county abounds in rivers. The three great rivers are the Lee, the Blackwater, and the Bandon. The Lee rises out of a lake in the west of Muskerry, called Gougane-Barra; after a course of about 26 Irish miles, it divides itself into two branches a little above Cork, and uniting again below the city, falls into the sea ten miles farther down, after affording upon its banks the finest scenery that can be conceived. The Blackwater rises in the mountains between Limerick and Kerry, runs eastward through the county till it en-

Cork. ters Waterford, and after a course of 80 miles, falls into the sea at Youghall Bay. The Bandon rises in the mountains of Carbery, and after a much shorter course than that of the other two rivers, falls into the sea at Kinsale. Besides these, there are innumerable other streams, all of which might be turned to good account were agriculture and manufactures in a prosperous state. Most of them have been immortalized in the poetry of Spenser.

Harbours. The whole coast of Cork, extending to about 37 leagues, is indented with creeks and bays; and affords numerous places of shelter and safety for shipping of the largest burden. Cork, Youghall, Kingsale, Crookhaven, Bearhaven, and Bantry Bay, though the most considerable, are but a few of the multitude of harbours and anchor-grounds with which this coast is furnished.

Fuel, plantations, &c. The fuel in common use is turf, which the poor can buy at a low price; and furze, of which sometimes whole fields are raised for the very purpose. There is also coal in the county, but its quality is not good. English coal is burnt in the sea-port towns, in none of which is it so high by 50 per cent. as it is in London. Some excellent and valuable wood is to be seen in this county. Mr Hyde sold, some time ago, 8000 trees, of 100 years growth, and covering 60 acres, for L. 10,000. There is still, however, a very extensive field for improvement in this respect. There are many thousands of acres which may be planted without much difficulty, and to great advantage. Formerly, there was a considerable quantity of timber, but the trees were cut down and consumed at the iron-works in the 17th century, and no adequate pains have been taken since to supply their place. Planting is now carried on by some individuals with great spirit. There are numerous orchards on the banks of the Blackwater, which are very productive. In various places there are nurseries for the cultivation and sale of forest trees.

Manufactures, &c. There are manufactures of various kinds in this county: of linen, sailcloth, duck, canvas, drilling, &c. In 1808, Sir T. J. Fitzgerald obtained bounty from the Linen Board on 112,782 yards of duck and canvas; and the same year, Mr Julius Besnard obtained bounty for 73,054 yards of sailcloth. Mr Besnard has a rope work at Douglas, two miles east from the city of Cork, with a walk of 232 feet long. At the same place he has two factories which go by water, at which he cards and rows hards, and spins all kinds of linen yarn, but particularly coarse. The young women employed here are not so depraved as in many other factories, because there are scarcely any of the other sex but old men. Within a few miles of Cork, Alderman Lane and Son have a woollen manufactory, where they dress cloth, after it is dyed, by means of machinery which cost about L. 5000, and where they employ altogether nearly a thousand people. In some parts coarse cloth, like Scotch Osnaburghs, is made and exported for negro clothing. The muslin manufacture has been introduced at Bandon. Gunpowder is made in the neighbourhood of Cork: it is the government manufactory of that article, and the only one in the kingdom. There are several breweries and distilleries of large extent; and cider is made from the fruit which grows on the banks of the Blackwater, &c.

Fish and fisheries. All the fresh water fish, salmon, pike, trout, eels, &c. are found here in great abundance, and, on account of the limestone-beds over which many of the rivers flow, are said to be of very superior quality. Herrings and other sea fish, which were once very plentiful on the coast of Cork, have almost wholly disappeared, and there is now no fishery worth mentioning. A good many sand eels, lobsters, craw fish, pearl mussels, &c. are caught; the sun fish, very large and valuable on account of the oil which it yields, is occasionally seen; and seals and porpoises frequent all the havens and headlands in great multitudes.

Minerals. The rocks most prevalent in the county are argillaceous. The greater part of the coast, and of the hills in its vicinity, is composed of a coarse red or grey sandstone, which often varies to a coarser and more slaty fracture; and in this we meet with slate, some of which is fit for roofing houses. Limestone is found in great quantity in almost every district, and at a cheap rate. A large seam of it commences in the peninsula of Cork bay, and the islands in Cork harbour, and extends on the south of the river Lee to a considerable distance. It contains a variety of fossil shells; and some of it, when scraped, has the unpleasant smell of stinkstone. In the limestone quarries near Cork, transparent quartz and large amethysts are found. The Galtee mountains are composed of a very coarse pudding stone, in which there is a great deal of iron shot quartz. Several quarries of marble, admitting of a good polish, and extremely beautiful, have been opened in the neighbourhood of Cork. This county is not destitute of coal. It is wrought on the barony of Duhallow, but is of a sulphureous stone quality, and not very good for domestic and culinary purposes. Charcoal is usually employed for kindling it. A bed or two, however, of superior purity, have been discovered, and are now the object of attention. There is abundance of iron-stone and some copper ore in the county; and both of them were formerly wrought with no small success, but the works have been long since discontinued. Ochre is widely diffused, and of a great variety of colours. A saponaceous earth, like fullers' earth, is found in abundance near the old head of Kinsale. About a mile west from Cloyne there is a stratum of clay, six feet thick, remarkable for being as white as snow, and made use of for whitewashing the walls of houses, taking grease out of boards, and composing glaziers' putty.

Weights and measures. The weights and measures used in this county, are, with a few exceptions, the same that are used throughout the kingdom. The cwt. weighs 8 stone, or 112 lb. The barrel of barley is equal to 3 kilderkins, and each kilderkin is 12 stone. The barrel of oats is equal to 3 kilderkins, and each of these kilderkins is only 11 stone. The English acre is used through all the southern parts of the county. Potatoes, when retailed in market, are sold by a measure called a weight, generally containing 21 lb.

Political divisions, &c. Cork is divided into 16 baronies, and 269 parishes. It returns eight members to the imperial parliament; of these there are two for the county, two for the city of Cork, and one for each of the burghs of Kinsale, Youghal, Bandon-Bridge, and Mallow: The voters for the county members are 20,000. It furnishes three regiments of militia; one for the city, another for the north district, and a third for the south district, of the county.

Ecclesiastical divisions, &c. The county of Cork contains the bishoprick of Cloyne, founded A. D. 600, and that of Cork and Ross, united A. D 1586. That of Cloyne contains 137 parishes; and that of Cork and Ross contains 127. The number of beneficed clergymen in the former is 56, and their collective revenue upwards of L. 40,000. The collective revenue in the latter amounts to L. 30,000. The income of the Bishop of Cloyne, according to Mr Young,

Cork.

in 1779, was L.2500, and according to Mr Wakefield it is now L.5000. That of the bishop of Cork and Ross, according to Mr Young, was L.2700, and according to Mr Wakefield it is now L.4500. These dioceses are under the Archbishop of Cashel.

Antiquities.

The principal antiquities of this county are the following: Subterraneous caves near the cathedral church of Roscarbery, of the origin and use of which there is no probable account: Round towers (of which there are so many in Ireland) one at Cloyne, one at Kineth, and the stump of one at Ballybeg; a very large tomb composed of enormous stones, situated about a mile east from Glanworth on the road to Fermoy; and circular monuments of stone, of which there are several remaining, in the mountainous districts.

Medicinal springs.

Dr Smith, in his natural and civil history of Cork, mentions and describes no fewer than 23 medicinal springs, mostly chalybeate, some of which have been found useful in scorbutic and scrophulous disorders. He also notices at length the warm springs at Mallow, on the south side of the town, but on the north side of the Blackwater river. They are frequented by invalids, who often derive benefit from the use of the waters.

Extent, population, &c.

The greatest length of this county is about 100 miles, and its greatest breadth above 70. It contains about 2653 square miles, or 1,697,820 acres. The number of houses, according to the parliamentary return in 1791, was 76,739, of which 56,422 paid for one hearth, 2344 were exempted as new, and 8949 as paupers, and the rest paid for more than one hearth. The number of inhabitants is computed to be 416,000. This gives 5.42 inhabitants to each house; 4.05 acres to each inhabitant, or 21.951 acres to each house; and 156.8 souls to a square mile. Mr Newenham makes the population of the county and city to be so great as 675,364, which gives 8.8 souls to each house. Of this population a vast proportion belongs to the Roman Catholic church. From a return made by the collector of hearth money, in 1732 and 1733, it appears that the Catholics were to the Protestants at that period, in the city, as more than 2 to 1, and in the county as 8 to 1. In 1740, the supervisors of hearth-money, in their return, made the number of Protestant families to be 4053. By the returns made in obedience to the order of the House of Peers, in 1766, it appears that, in the diocese of Cork and Ross, there were 4814 Protestant families, 23,039 Catholic families, 25,471 Protestants, and 108,634 Catholics. In the diocese of Cloyne, there were 1534 Protestant families, and 12,971 Catholic families. The number of individuals was not returned; but making the number of individuals in a family the same in that diocese as in the other, the number of Protestants would be 8130, and the number of Catholics 60,963. At present, according to Mr Newenham, in the city of Cork, and the towns of Youghal, Bandon, Kinsale, and Cloghnikilty taken together, the proportion of the Catholics to the Protestants is more than 6 to 1; and in the other towns of the county not less than 12 to 1. In the three regiments of militia, the proportion among the privates (for their officers are almost all Protestant,) is upwards of 7 to 2. See Beaufort's *Memoir of a Map of Ireland*; Smith's *Natural and Civil History of Cork*; Hall's *Tour through Ireland*, vol. i.; Wakefield's *Statistical and Political Account of Ireland*; and Townsend's *Survey of Cork*. (τ)

CORK CITY, the capital of the county of Cork, and the second town in Ireland. It is situated on the river Lee, which is here of considerable size, and contributes equally to its local beauty and commercial advantage. On all hands it is surrounded by high ground. It stands partly upon an island formed by the Lee, as Spenser describes it in these lines,

> "The spreading Lee, that, like an island fair,
> Encloseth Cork with his divided flood;"

but it lies chiefly on the south bank of the river. From its being placed in a hollow, and having few spires, it has a dull appearance when seen from a distance. It is said to be unhealthy, there being but an inconsiderable number of the inhabitants who live till eighty, and the military who are quartered there suffering soon and much from disease. There are several bridges over the Lee. Of these the handsomest is St Patrick's, over the north channel. It is considered as one of the finest structures of the kind in Europe. Some of the streets are extremely dirty—a few of them, such as the Parade, Newbridge Street, &c. are straight and clean, elegant, and even showy. The old custom-house is an extensive building, and on the eve of being superseded by a new and more suitable one. The public markets, which are situated almost in the centre of the town, are very neat and convenient. The court-house and exchange are tolerably commodious. The new barracks cost government £80,000, and are capable of containing 4000 infantry, and 1000 horse: the old barrack is retained; and there is besides a barrack for the artillery. There are many handsome houses, both in the city and its neighbourhood, belonging to opulent individuals. Cork contains a cathedral and seven or eight churches belonging to the establishment, besides a great number of chapels and meeting-houses for the Dissenters and Roman Catholics. Upper Shannon church stands on an eminence, and has a tall spire, which is seen at a distance. There are two theatres, and about 500 ale-houses and taverns. There are here plenty of schools, Protestant and Catholic, which are well attended, though not always judiciously taught. There is also a public library, well stored with books, supported by 200 subscribers, at the rate of 1½ guineas entry money, and 1 guinea per annum. An "Institution for applying Science to the common Purposes of Life," has been established, and is in a flourishing state. It originated in private subscriptions. It has a good collection of minerals, a scientific library, and apparatus necessary for illustrating lectures in natural philosophy. Government have given it L.2000, and ground is already procured for a Botanical Garden. There are two Foundling Hospitals, one for the Protestants, founded in 1747, containing generally about 300 children, and supported by a tax on coal; and another established lately by the Roman Catholics for their own communion:—a school of industry, where 50 boys and as many girls are taught the ordinary branches of education and industry—an infirmary—a hospital—a workhouse—a house of recovery, intended chiefly to prevent the spread of contagious diseases—a charitable repository, to which ladies send needle-work to be disposed of for the benefit of the poor—a house of industry, containing an infirmary, house of correction and madhouse, having 200 people in all, and costing annually from L.4000 to L.5000—and many other benevolent institutions.

The bay and harbour of Cork are situated about seven or eight miles farther down the river. In the harbour there is an island of considerable extent, called Great Island, containing the town and quay of Cove. Vessels of 120 tons can go up to the city quays; but the large ships lie at *Passage* a few miles lower down.

The harbour is capable of containing an immense number of ships in perfect security, and is now a place of rendezvous for fleets destined to the West Indies. Its mouth is defended by Carlisle fort. The fortifications on Spike Island are said to have cost a million sterling.

Manufactures of various kinds are carried on—linen, checks, carpets, glue, gunpowder, glass, &c. There are four distilleries, besides five or six rectifiers of spirits, who work under special licence from the commissioners of excise. The greatest distillery, carried on by Mr Walker, makes 17,000 gallons per week, and works from 9 to 10 months in the year. The other, belonging to Messrs Hewson and Co. produces 9000 gallons per week. The former is said to pay L. 200,000 per annum of duty to government. Besides many breweries for ale and small beer, there are five for porter. The principal one belongs to Beamish and Crawford, who brew 2000 barrels of 46 gallons each per week, which they sell at 10 d. per gallon.

The principal exports of Cork are salted provisions, beef, pork, and butter, which are collected there, for being shipped, from all the southern parts of Ireland. At an average 10,000 oxen and 8000 cows are slaughtered annually. In 1807, about 3600 head of cattle were killed and 50,000 hogs; but it appears the slaughtering of the former is on the decline, and that of the latter on the increase. Dr Smith says, that the number of cattle slaughtered from August to Christmas, in each year, was little less than 100,000. In 1791, upwards of 50,000 barrels of beef, and about 7000 tons of butter, were exported. In 1806, the quantity of butter was 160,000 cwt. One half of the hides procured at Cork are exported; the other half, consisting of the heavy ones, are retained at home for shoe leather. All the linens and woollens from the south of Ireland, intended for a foreign market, are shipped here. Corn, also, porter, tallow, and cattle-hoofs, are exported. From a report made to the House of Commons, it appears, that in 1791 there was exported 49,080 barrels of corn—23,374 cwt. of flour, meal, and bread—55,525 barrels of beef—38,948 barrels of pork—13 live hogs—139,507 cwt. of butter—and 1,197,729 yards of linen cloth. In 1802, 185,059 gallons of Irish spirits were exported from Cork; in 1803, the quantity was 492,665 gallons; in 1804, it was 340,965 gallons; in 1805, it was 311,241; and in 1806, it was 199,027. The imports of Cork are chiefly those ordinary articles of consumption, such as groceries, coal, &c. which are not otherwise found in the resources of the city and county.

Prices of Ox and Cow Hides, Rough Tallow, and Grain, at Cork, furnished to Mr Thomas Newenham by Mr Hacket, Farmer, Mr Hawkes, Tallow-chandler, and Mr Good, Corn Merchant, 30th October 1811.

In November 1808 there were five bankers in Cork. One of them has since failed for L.420,000. There was also a discount office. In 1804, the private notes in circulation from the Cork banks were thought by Mr Roach to be L. 1,000,000. Mr Beresford estimated them at L. 600,000.

At each entrance to the town there is a gate; but no police has yet been established for preserving its order, and attending to its economy. The corporation consists of a mayor, two sheriffs, a recorder, and several aldermen. The mayor is chosen by a kind of lottery. No one is styled alderman till he has been mayor. The mayor, while in office, has a salary of L. 500 per annum. Cork is the seat of a bishop. It sends two members to the imperial parliament. The electors are composed of about 1500 freemen of the city, and a number of freeholders in the county of the city, which is pretty extensive. The population of this city has been variously estimated. In the year 1732, according to a return of the collectors of hearth money given by Dr Smith, it amounted to 55,769, of whom 17,983 were Protestants, and 37,786 Catholics; there being 2569 families of the former, and 5398 families of the latter. According to Dr Beaufort, the number of inhabitants, in 1791, was nearly 73,000, distributed among 8100 houses, which gives about 9 to a house. Mr Newenham says, that, according to an accurate enumeration made at his request by the Roman Catholic clergy, within the four years preceding 1811, there are in the city, *exclusive of the liberties, which are very populous*, 6416 inhabited houses, and 55,265 inhabitants, of whom 45,205 are Roman Catholics, and 10,060 Protestants; making in the whole an increase to the population since Dr Smith's estimate, of all that may be supposed to inhabit the liberties. Mr Wakefield thinks that there may be about 80,000; while others make the number several thousands more. Cork is situated in 51° 53′ 54″ North Lat. and 8° 30′ West Long. It is 161 miles south-west from Dublin. See *the works referred to at the end of last article.* (τ)

CORN, in agriculture, is said properly to mean "grain in the ear," or "grain unthrashed," but is generally taken in the much more comprehensive sense, of grain fit for food in whatever stage of preparation. Wheat, rye, barley, oats, &c. and, according to the current language of many farmers, even pulse, as pease and beans, come under this denomination. Under the head of AGRICULTURE, we have treated so fully of the various modes of raising corn, that the only subject which at present remains to be considered is our system of corn laws.

CORN LAWS form altogether a large body of enactments in our statute books, as they embrace the home as well as the foreign trade in grain. Few departments of our code have excited more serious difference of opinion; the political economists contending, that the corn trade should be left wholly free and unfettered, while the agriculturists insist, that it is indispensible for the good of husbandry, to prevent, by means of public regulations, the fall of grain below a specified rate. The opinion of government has varied, as we may naturally imagine, in different ages, according to the preponderating interest, or according to the different degrees of information possessed at the time. On one occasion we find it a prevalent opinion, that corn was too good a commodity to sell to our neighbours; on another, that the more we sold the better, because by that means additional sums of money were brought into the kingdom. The former was, and will continue to be, the natural feeling of the consumers, that is, of the people at large; while the latter may be regularly expected to influence the landholder and farmer. The crown, or executive power, looked by preference at revenue, and cared, in former ages, very little whether we sent our corn abroad, or imported that of foreign nations, provided the one or the other could be rendered instrumental in filling the coffers of the treasury. However, for the last century, all idea of raising revenue from corn has been relinquished, and the executive power has been actuated by other considerations, viz. the desire of uniting the landed interest in support of a war, by passing acts to raise the price of corn when it was low; and, on the other hand, a wish to prevent popular discontent, by favouring the import of foreign corn, when our own markets had reached an exorbitant height.

The subject of corn laws naturally divides itself into two parts; a narrative of our past proceedings, and a disquisition on the principles which ought to regulate this branch of trade. We begin with the former.

I. *Historical sketch of our Corn Laws.* The first law relative to the exportation of corn occurs in the year 1360, and contains a prohibition of sending our corn abroad. In the succeeding reign, in 1394, a counter-edict was passed, and all the king's subjects were authorised to export corn on payment of the ordinary duties. In that rude age, government were far from ascribing to the encouragement of export any ultimate effect in cheapening prices at home. Notwithstanding the temptation of revenue, the prevalent bias was to keep our corn at home, in conformity to which the law long continued to permit the import of foreign corn. In 1436, the export of English corn was put under more definite limitations, being declared legal only so long as our own currency should be at a moderate rate, corresponding to 35s. per quarter for wheat at the present day, and 16s. for barley. Such continued to be the law of the land for nearly a century; and the leading motive was evidently a desire to keep our provisions at home whenever prices were high, a result which might have been very safely trusted to the natural course of things. In the year 1552, however, a farther and a very decided step was taken for the discouragement of the export of corn, an act being passed to prohibit it so long as wheat should be above a price equivalent only to 17s. of our present money the quarter, or barley above the equally low price of 8s. 6d.

In regard to the import of foreign corn, the first discouragement of importance consisted in an act passed in 1463, which contained an absolute prohibition of introducing it into the kingdom, unless our own prices exceeded 35s. (present money) for wheat, and 16s. for barley. Our corn growers however complained, that the act was of little efficacy, partly from remissness at our custom-houses, and partly from the rapid diminution in the quantity of silver coined in the shilling, the effect of which, in the course of time, was to make the nominal sum above-mentioned equal only to half its value. Of course, as the quarter of wheat could very seldom fall below 16s. or 17s. the practical consequence was an almost perpetual liberty to import. But in the reign of Elizabeth, new regulations were framed, and allowance was made for the altered value of the currency After re-enacting the old laws, which enjoined, in positive terms, the tillage of the land, and rebuilding of farm-houses, her ministers, proceeding on the comparatively new principle, that it was politic to encourage export, procured an act of parliament for permitting it so long as corn should not exceed a rate which, in wheat, was equal to 28s. a quarter of our present money, and in barley to 16s. 7d. The price of 28s. although inferior to the rate which we have just mentioned, as enacted in the preceding century, was greatly superior to the actual value to which that rate had by this time fallen, by the reduction of the quantity of silver contained in the shilling.

This first modification of our corn laws in the reign of Elizabeth, took place in 1562. In 1570, there was passed an act, apparently of much greater latitude, permitting the export of corn without limitation of prices, whenever there should be no existing prohibition; but the accompanying imposition of a duty of 10 *per cent. ad valorem* on the export, operated as a deduction from the efficacy of this ostensibly important privilege. The provisions of the act deserve attention in two respects; first, as indicating a continued belief of the policy of raising a tax from corn exports; and, secondly, as proving the remarkable diversity of price in different districts. In the present age of extended communication, and multiplied means of carriage, we can with difficulty form an idea of the effect of the impediments at that time on the exchange of commodities between one district and another. A journey of a hundred miles was in those days the labour of a week, and performed with considerable hazard through sloughs, across mountains, and over rivers without bridges. The miserable method of carrying corn and other commodities in sacks on horseback, was consequently much more common than the apparently obvious plan of cart or waggon carriage. We must, therefore, be cautious how we draw conclusions in regard to the general price of wheat from the local reports of former times. Besides, wheat being then the food of the richer classes only, was not, as at present, an index of the relative prices of the ordinary diet of the lower orders.

Another cause of fluctuation in those days, was the rigour of the law against the supposed offences of forestalling, regrating, and engrossing. Though the popular mind has, for many ages, been stimulated in favour of these laws, by the plea that they conduce to keep down the markets, the original motive for their enactment was of a very different description. A duty, or toll, was levied in the different markets and fairs of the kingdom, and was paid partly to the royal treasury, partly to the baron who possessed the landed property of the surrounding district. It became an object with purchasers, as well as sellers, to attempt the evasion of these duties, and to endeavour to make their bargains on the road, or in places distinct from the public markets; hence the laws enacting a compulsory attendance at these markets,—laws of much the same character, in respect to equity or policy, as the statutes passed to maintain tillage, and restrict pasturage, by dint of penalties. The exportation of wool to the continent, particularly to the manufacturing country of Flanders, had, in the fourteenth and fifteenth centuries, become considerable, and had rendered government apprehensive, that the frequent conversion of corn-land into sheep walks might injure the prosperity of the kingdom. Accordingly acts for the increase of tillage were successively passed in 1488, 1515, 1534, 1552, and 1562.

Towards the end of Elizabeth's reign, the prices of corn rose to a high rate, wheat being in 1596 and 1597 at the price of £4 a quarter. The importation of corn continuing unrestricted, we are to account for the duration of this rise in price by a succession of indifferent harvests at home, and by the very limited means of that age, either of importing from abroad, or of distributing foreign corn into the interior when it had actually reached our harbours. The former low prices being in a manner obsolete, the law relative to exportation underwent a change, and liberty was given to send grain out of the kingdom, though prices should be beyond the former limit. But as a duty of 2s. a quarter on wheat, and 1s. 4d. on other grain, was still collected, the permission of export was in some degree counteracted. During the pacific reign of James I. two acts took place in regard to the corn trade. Both enforced the above-mentioned duties, and both made a partial extension of the limits at which exportation became lawful. By the last act, passed in 1623, wheat was exportable so soon as our home currency fell to 32s. a quarter, and barley at 16s. As these were, not unfrequently, the actual rates in particular districts, it is probable that various exports took place, and that a considerable revenue was collected from this source.

During the unsettled period which followed the accession of Charles I. we meet with no alterations in the existing system of corn laws. The Restoration, however, gave rise to fresh enactments, founded partly on a consideration of the wishes of the landed interest, partly on a scheme of revenue. Exportation was permitted at any time when wheat at home should not exceed the price of 40s. and barley 20s. The laws relative to importation were also new modelled; foreign corn being, in a manner, excluded so long as our own market was at a reasonable rate (44s. for wheat); and being burdened with a duty of 6s. 8d. a quarter, even when our own prices were high. In addition to the object of revenue, the view of government in these laws was perhaps to proportion, as nearly as possible, the national growth of corn to the national consumption. However, prices in the succeeding years rising very high, importation was allowed by an act in 1663, without reference to the state of home markets, at the comparatively moderate tax of 5s. 4d. on a quarter of wheat, and 2s. 8d. for barley. Such was the law in England during seven years. In 1670 there was passed a fresh act, which seems to discover a marked attention to the views of the landed interest. By this act, foreign corn was loaded with a high duty so long as our own could be afforded at a reasonable rate (53s. 4d. for wheat); while exportation was declared lawful without reference to the state of markets, but always with the obligation of paying an export duty. The actual state of the corn trade during the chief part of the reign of Charles II. is said to have been a suspension of export, and a partial admission of import, our market prices being generally so high as to admit foreign corn at the duties prescribed by the act of 1663.

We have now arrived at the æra of 1688, an æra as important in the history of our corn laws as of our liberty, however different the merits of the measures respectively adopted. The Revolution was the epoch of the reinstatement of the authority of parliament; and it is here the place to remark, that the laws which profess to favour the landed interest at the expence of the nation at large, proceed not from the crown, which has no interest in such enactments, and still less from the people who are the sufferers, but from the members of our legislature, in other words the great proprietors of land. This is easily shewn by a retrospect to the proceedings of government. During the suspension of parliaments under Charles I. and during the virtual abolition of their authority under Cromwell, no measures were taken in favour of landholders. But in 1688, no time was lost in encouraging the export of corn by the new expedient of a bounty. An act was passed declaring, that whenever wheat in the home market should be at or below 48s. and barley at or below 24s. there should be allowed a bounty, or export, of 5s. a quarter for wheat, and 2s. 6d. for barley. Mr Dirom and other advocates of the bounty system, are so enamoured of this law, as to be unable to refrain from expressing their surprise that it should not much sooner have engaged the attention of our ancestors. The grand argument brought forward in its favour, is its tendency to prevent the occurrence of scarcity, by inducing the farmers to raise a surplus stock of corn. The real view, however, regarded an object more directly resulting from it, namely, the raising of the rent of land, farmers being induced to come under contract for a larger rent, when assured, by the first authority in the country, of the permanency of a high currency for their produce. By a subsequent act in 1700, every thing in the shape of duty on English corn, ground or unground, was relinquished by the crown; and in 1707, on the union with Scotland, the operation of the corn laws was rendered similar throughout Great Britain.

The acquiescence of the crown in the remarkable innovation produced by the act of 1688, is to be chiefly ascribed to King William's solicitude to unite the leading men in the country in his great contest against Louis XIV. A similar motive actuated government during the reign of Queen Anne; and before the conclusion of our long struggle with France, the bounty system had become consolidated with the laws of the land. It was accompanied by restrictions on the import of foreign corn, of so heavy a nature as almost to amount to a prohibition. The result of the bounty was, as may naturally be conceived, a large exportation in years of favourable crop. After the peace of Aix la Chapelle, for example, the average exportation for four years was above 1,200,000 quarters each year; while the price of wheat for the same time was only 36s. 3d. a quarter. It is a curious fact, that the bounty system had not, on taking a comprehensive view of its operation, the effect of creating a general or permanent rise of prices. On comparing the seventy years which followed the enactment of the bounty with the seventy that preceded it, we shall find (*Wealth of Nations*, vol. i. p. 418) that the price of wheat was considerably lower in the latter period. There seems little doubt that the bounty, by carrying cultivation at first too far, counteracted the object of its short-sighted projectors; and rendered our growth of corn disproportioned to our consumption. Whatever may have been the cause, the fact was, that prices did not assume the character of a progressive rise till after 1760. By that time the increase of our population employed in navigation, manufacture, and trade, began to be such as nearly to equal by their consumption the produce of the agriculturists. It is to this cause, and by no means to the imagined effect of corn laws, that we are to attribute the flourishing state of the landed interest in our own time. So long as the bounty system was unaided by any thing like a considerable advance in the general prosperity, that is, duing the first sixty years of last century, "no rise of rent was ever thought of, and lease after lease, in long succession, were signed without a word passing upon the question of rent; that was an object considered as fixed, and grandfather, father, and son, succeeded without a thought of any rise; in many cases landlords were much more apprehensive of losing a tenant at the old rent than having the smallest conception of raising it to a new one." *

The rapid rise in the price of corn during several years preceding 1773 induced government to resort at first to temporary prohibitions of export, and to a disuse of the mistaken enactments of former ages against the intervention of middle men in the corn trade. In 1773, there was taken the decisive step of abrogating the bounty on the export of corn, until our markets should fall below the price at which it was formerly allowed, viz. until wheat should be at the current rate of 44s. a quarter, and barley at 22s. This was little else than withdrawing the bounty *in toto;* but what was of more direct influence on our corn-market, was the abolition of the restraints on the importation of foreign grain, the same being admitted at a very trifling duty, so long as the currency of our markets should be at or above 48s. for wheat, and 24s. for barley. This revolution in our corn-laws has been ascribed to the enlightened influence of Dr Smith and Mr Burke, but arose more immediately from a consideration of the popular discontent attendant on the rapid advance of prices. The object of government, an object which has, more or less, actuated our subsequent corn statutes, was to maintain, as far as the uncertainty of seasons would allow, a kind of level in the currency of our corn market. The advocates of the bounty system were loud in declaiming against this decided change in our policy, and have ascribed to it that reduction and almost total cessation of our corn exports, which may be much more justly and satisfactorily attributed to the increased consumption attendant on an augmented population at home. They are by no means disposed to subscribe to the fundamental assumption of the act, viz. that the price of 48s. was fair both for grower and consumer, or to the policy of calling in a foreign supply whenever our markets should exceed that rate. Government, however, have adhered stedfastly to the principle of endeavouring to keep corn as near a level as possible, and have been actuated by it on the two occasions (in 1791 and 1804) on which our corn laws have undergone a modification. The former of these was little else than a slight alteration in the specified rates of 1773, in consequence of the fall in the value of money.

In 1804, by a farther extension of the specified rates, the importation of foreign corn was, in a manner, prohibited so long as our own was sold at 63s. and it was burdened with a duty until our own should reach 66s.

Abstract of the Corn Bill of 1804, as far as regards Wheat.

When our own wheat sells at home at or below the average of . . . . 48s.
there is a bounty of 5s. a quarter on export.

On our average rising to . . . . 54s.
our wheat is no longer exportable.

When our average rises above . . . . 63s.
foreign wheat is importable at a duty of 2s. 6d.

And when our average rises to . . . . 66s.
foreign wheat pays only a duty of 6d. a quarter.

With the view of giving a preference to the produce of Canada, the act directs that the wheat of British colonies shall be admissible at a duty of 2s. 6d. whenever our home average exceeds . . . . 53s.

And at the low duty of 6d. whenever it exceeds 56s.

The fall of price consequent on peace, and on the favourable harvests of 1802 and 1803, had alarmed the landed interest, and induced them to extort from government the above act, which was productive of much popular discontent, and which the result has shewn to have been wholly unnecessary. The landholders were apprehensive of being unable to keep up their rents, and ministers eager, like King William, for the cordial support of the men of property in the war with France, assented to that which they were hopeful would produce only a temporary dissatisfaction. But as all parties were agreed that the contest with France was likely to be of long duration, and attended with burdens which would materially depreciate money, or, in other words, raise the price of corn, the matter might have been safely left to the unaided operation of these causes. The fact is, that since 1804, our average prices of wheat have been *constantly above* 66s. and the provisions of the act have been consequently unnecessary. They may be applicable, however, in the event of peace, and of a large free importation from abroad.

Having finished the narrative of our corn laws, we proceed to adduce a few tables calculated to shew the progressive changes in this branch of trade. Dr Anderson has exhibited the following Table of the

Average prices of wheat in England from the year 1650 to 1700.

		s.	d.
For 10 years preceding	1650	59	5
10	1660	58	8
10	1680	54	0
10	1690	46	11
Average of 40 years		59	9
1700, by itself, was so high as		68	3

No account of exports or imports was kept until 1697. At that time the effects of the bounty system in leading to exportation began to be apparent.

Exported more than imported in wheat and other grain of all kinds.

			Average price of wheat. s.	d.
4 years preceding	1700 on an average	80,000 qrs.	58	1
10	1710	284,000	51	10
10	1720	449,000	37	0
10	1730	375,000	36	6
10	1740	541,000	37	6
10	1750	833,000	23	8
Average price of 50 years			36	2

		s.	d.
The year of our greatest exportation was 1750, the quantity sent abroad being no less than	1,667,000	32	6

* Young on the Progressive Value of Money, p. 102.

			s.	d.
10 years preceding	1760 on an average	545,000	42	6
5	1765	573,000	42	2

During these 15 years, the great rise in the price of corn began to produce a very different feeling in regard to the policy of our bounty system. It was, in fact, the interval during which our consumption was coming round, first to an equality with, and eventually to an excess over, our importation. Increase of population now led to a reverse of the picture, and we are henceforth to state the

Excess of Imports over Exports.

		Price of Wheat. s.	d.
5 years before 1770	247,000 qrs.	53	1
5 1775	505,000	49	10
5 1780	27,000	38	7
5 1785	267,000	47	2
5 1790	412,000	45	6
5 1795	1,184,000	52	6
5 1800	2,138,000	66	6
Average of 50 years		49	5

The year 1800 was the one of greatest importation, the excess of export over import being no less than 2,939,000 qrs. and the average price of that year being so high as 110*s.*

It is thus apparent that our dependence on foreign countries for a supply of corn has arrived at a very serious extent. The experience of the last ten years is in correspondence with the conclusions to be drawn from the latter part of the above table; and even with the benefit to be derived from the labour of additional hands in time of peace, we shall not be safe in estimating the annual imports required in corn of all sorts at less than 1,500,000 qrs.

In the Baltic, Dantzic being the great port for exportation, the prices there afford a criterion for the currency of the other markets along the coast, while they are themselves regulated by the state of the English markets.

Export of wheat from Dantzic, from the year 1793 *to* 1803, *inclusive; stated in* lasts, *and taken from the annual accounts published in that city. The* last *being a measure of* $10\frac{1}{4}$ *quarters.*

Years.	To England. *Lasts.*	Other parts. *Lasts.*	Total. *Lasts.*
1793	9,451	5,963	15,414
1794	6,244	12,529	18,773
1795	4,283	9,491	13,774
1796	20,407	6,474	26,881
1797	17,496	6,398	23,894
1798	18,357	7,991	26,348
1799	16,713	8,311	25,024
1800	37,202	3,661	40,863
1801	33,748	3,855	37,603
1802	27,028	25,388	52,416
1803	11,725	22,424	34,149

Ireland has, particularly of late years, become one of our great sources of supply. After much jealousy on the part of British landholders, and repeated restrictions on the admission of Irish corn into Great Britain, government was at last, in 1806, enabled to pass an act "permitting the free interchange of every species of corn between Great Britain and Ireland." An end was thus put to the impolitic list of duties on grain, meal, flour, bread, &c. imported from the sister island, and a trade, considerable at that time in spite of custom-house difficulties, has recently become one of the greatest importance to both countries. The following short table conveys an idea of its extent prior to the operation of the act of 1806.

A Return of the Quantity of Grain and Flour exported from Ireland from 1802 *to* 1807 *inclusive.*

Years.	Wheat.	Oats.	Other Grain.	Wheat, Flour, and Oatmeal.
	Barrels.	Barrels.	Barrels.	Cwt.
1802	168,937	475,066	16,180	199,810
1803	101,901	391,102	37,402	119,762
1804	152,828	372,690	24,652	88,826
1805	134,871	346,244	38,917	57,071
1806	153,214	461,700	26,640	79,665
1807	68,003	724,347	76,010	56,661

Since 1807 the agriculture of Ireland has been greatly extended, and her exports of corn have been much larger. Oats form the principal article; and in 1809 the importation of them into England was nearly 800,000 quarters. The progressive advance in the price of wheat is indicated by the following

Return of the annual average Prices of Wheat in Ireland from 1784 *to* 1809 *inclusive.*

Years.	Per barrel of 20 stone.	Years.	Per barrel of 20 stone.
1784	£1 8 0	1797	£1 6 $8\frac{1}{4}$
1785	1 3 $3\frac{3}{4}$	1798	1 7 $4\frac{3}{4}$
1786	1 3 8	1799	1 12 $4\frac{1}{4}$
1787	1 3 $2\frac{1}{4}$	1800	2 16 $4\frac{1}{2}$
1788	1 2 4	1801	2 16 7
1789	1 6 11	1802	1 11 $6\frac{3}{4}$
1790	1 8 $2\frac{1}{4}$	1803	1 9 $0\frac{1}{2}$
1791	1 6 $1\frac{1}{2}$	1804	1 9 10
1792	1 3 $4\frac{1}{2}$	1805	1 16 $7\frac{1}{2}$
1793	1 5 $9\frac{1}{2}$	1806	1 19 6
1794	1 10 $10\frac{3}{4}$	1807	2 0 1
1795	1 14 $10\frac{1}{4}$	1808	2 4 $9\frac{1}{2}$
1796	1 18 5	1809	2 7 $3\frac{3}{4}$

The west coast of Scotland is, in general, very unproductive of corn, so that a brisk trade of import, particularly in oats, is carried on with the sister island. In 1809, the quantity of oats imported from Ireland to Scotland amounted to 402,000 quarters.

The average price of wheat in Scotland is considerably lower than in England, a difference to be attributed partly to the greater distance from the metropolis, the great scene of consumption, and partly to inferiority of quality.

Return of the annual average Price of Wheat in Scotland from 1771 *to* 1809 *inclusive.*

Years.	Wheat, per quarter.	Years.	Wheat, per quarter.
1771	39*s.* 6*d.*	1774	42*s.* 2*d.*

An Account of the quantity of Wheat and Wheat-Flour imported into England from the United States of America and other Foreign Countries, from the 5th January 1804 *to the 5th January* 1810.

Years.	Wheat. From the United States of America.		Wheat. From other foreign countries.		Wheat-Flour. From the United States of America.			Wheat-Flour. From other foreign countries.		
	qrs.	b.	qrs.	b.	cwt.	qr.	lb.	cwt.	qr.	lb.
1804			324,639	5	14,478	1	16	41	3	0
1805			780,778	1	46,966	1	19	5,581	0	27
1806	8,987	0	95,055	5	240,227	2	18	15	0	4
1807	102,328	3	65,100	1	466,715	2	2	2,175	2	18
1808	8,924	5	7,295	5	13,685	2	13	315	0	20
1809	34,569	7	187,900	3	439,830	0	2	411,024	2	19

In peace, it is likely that our imports from America will much exceed the limited quantity received in the above mentioned years.

We are next to exhibit a computation of the proportion of land cultivated for different purposes in England and Wales.

	Acres.
Wheat	3,160,000
Barley and rye	861,000
Oats and beans	2,872,000
Clover, ryegrass, &c.	1,149,000
Roots and cabbage, cultivated by the plough	1,150,000
Fallow	2,297,000
Hop grounds	36,000
Nursery grounds	9,000
Fruit and kitchen gardens, cultivated by the spade	41,000
Pleasure grounds	16,000
Land depastured by cattle	17,479,000
Hedge rows, copses, and woods	1,641,000
Ways, water, &c.	1,316,000
	32,027,000
Commons and waste lands	6,473,000
Total acres in England and Wales	38,500,000

In a late publication of Mr Arthur Young, (*Inquiry into the Progressive Value of Money*, p. 99,) we find the following computation of the change in the rate at which land has been sold at different periods:

	Years purchase.
Sixteenth century	10
Seventeenth century	$16\frac{1}{4}$
1712 to 1737	22
1768 to 1773	32
1778 to 1789	$23\frac{1}{4}$
1792 to 1799	27
1805 to 1811	28

In the same work we find a calculation, in some respects necessarily a matter of guess, of the progressive rise in the price of corn. Classing together three sorts of grain, and taking the No. 20. as the representative of the average price in the seven years preceding 1810, Mr Young computes the preceding proportions as follows:

	Wheat, barley, and oats classed together.
Fifteenth century	3
Sixteenth ditto	5
Seventeenth ditto	$8\frac{3}{4}$
Eighteenth ditto	$10\frac{1}{4}$
66 years, from 1701 to 1766	$7\frac{1}{2}$
(During this period the bounty had been in operation.)	
34 years, from 1767 to 1800	$11\frac{3}{4}$
14 (repeating ten years) from 1790 to 1803	$14\frac{1}{2}$
7 years, from 1804 to 1810	20

II. *Principles of our corn laws.*—We shall now proceed to consider the principal arguments urged in favour of a bounty, and of an interference on the part of government in regard to the corn trade. A bounty, say the writers on the side of the landholders, leads to export, which, while it assures us of plenty at home, has the effect of bringing in money from other countries. Now, the extent of advantage resulting from exports, at least from forced exports, has been discovered of late to be much less than our ancestors imagined. No article will bring money, without having cost an equivalent in one way or other. The money obtained for exported corn, so far from being clear gain, is merely an indemnity for the land, the labour, and the capital applied to it. Had the same land, labour, and capital, been directed to a different purpose, such, for example, as raising hemp or timber, or feeding cattle, the chance is, that the product might have been equally beneficial; and, for aught the advocates of the bounty system can shew, it might have been more beneficial both to the individual and the public. In this, as in other branches of trade, the plain rule is, to let things take their course, and to allow the landholder or farmer to grow whatever article the state of the market points out as most advantageous to him. Viewed in a comprehensive light, it is just as impolitic in government to give 5s. a quarter bounty on the export of corn, as to discourage its export by a 5s. duty. The plea, that corn, being an article of indispensible necessity, cannot be too much encouraged by government, has no foundation in that state of society where the wants of one country can be supplied from another. Recent experience has shewn, how unavailing are the attempts of the most despotic government to interdict the course of commerce. The experiment has been pushed to the utmost, and is not likely to receive a second trial. Europe appears to be again coming round to the state in which each country may account herself at liberty to employ her labour and her capital in the way most conducive to profit, and with little necessity of giving an artificial direction to particular branches of industry, in consequence of political considerations.

Our next argument goes a good deal farther, and will appear not a little extraordinary to the advocates of our corn laws. It is nothing less than that the bounty granted in King William's time, and accounted a signal advantage by our landholders, was, in fact, productive of very considerable injury to them and their posterity. By pushing the cultivation of corn, that is, by throwing into it an extra proportion of labour, capital, and even of land, the matter was overdone, and corn rendered a drug for half a century. To what other cause can we attribute the inferiority of price, already mentioned, in the period of seventy years after the bounty, compared with the seventy years before it, or compared with the course of things since the bounty has ceased to operate? Under such circumstances, needs it be matter of wonder, that there should have been "difficulty in finding a good tenant at the old rent, and that a rise should have never been talked of?" We are far, however, from ascribing similar effects to the other part of the corn laws; we mean the discouragement of the import of foreign grain. Of this, the effect is evidently and incontrovertibly to keep up the price of our home produce. Whether this artificial enhancement is, in the long run, advantageous to the farmer or landholder, is a very different question. We are strongly inclined to doubt its favourable tendency to them; because, as we shall show presently, a rise in the price of corn creates a correspondent rise in the articles on which their income is expended, and with which, in a great measure, their business is carried on. Farther, as the enhancement of corn is unquestionably a national loss, the farmer, and still more the landholder, can hardly escape a portion of the general deterioration. Experience, however, proves, that it is vain to expect men to prefer a remote to a present advantage. The landholders under King William had no hesitation, we have seen, in contending for a bounty, which was to bring them a certain immediate benefit, at the cost of a much larger sacrifice from their sons and inheritors. In like manner, the discouragement of supplies from abroad, seems to absorb all other considerations in the minds of the parliamentary leaders of the country interest at the present day. As the law now stands, it has fortunately no operation until the currency of our wheat falls to 66s.; and if a farther extension be not insisted on, the public are not likely to recur with discontent to that which is past, and is in a manner incorporated with our habits and calculations.

We are now to enter on the arguments for questioning the generally diffused opinion, that a rise in the market-price of corn is advantageous to the farmer and landowner. To make our reasoning on this point intelligible, it is requisite to point out the distinction, and a very important one it is, between money-rent and real rent. When the price of a quarter of wheat has risen from 50s. to 70s. the *money* rent rises in proportion, but, in consequence of an accompanying rise in other commodities, the larger sum of money buys no more of the elegancies and comforts of life than the smaller did before. An increase of *real* rent takes place, when the sum paid by the tenant will buy more of these elegancies and comforts than it did before.

These fluctuations of rent, so different from each other in their effect, originate in very different causes. An increase of mere money rent is caused by the depreciation of money; an increase of real rent is caused by the advanced prosperity of the country.

Let it be kept in mind, that there are three stages in the state of every country: the stationary—the advancing—the declining. The signs of an advancing state, as regards agriculture, are, an increasing demand for corn at home—a gradual diminution, and, finally, a cessation of the export of corn. These signs of agricultural prosperity owe their existence to the prosperity of trade, for the plain reason, that the various hands supported by commerce and manufactures are all consumers of the fruits of the earth. This increase of consumers at home, lessens the necessity of seeking for consumers abroad; so that the diminution of the export of grain, so much regretted by superficial observers, is always a favourable token, unless when caused by a decay of agriculture: a decay which never takes place under a good government. In proof of this, no countries at present export grain largely except North America, which is thinly peopled from being newly settled; and Poland, which is thinly peopled, from having long had an oppressive government.

If we inquire in what particular manner the prosperity of trade enhances land, we shall find that it causes this enhancement in two ways; first as a source of income, and next as a permanent property. It increases the value of income or rent, by multiplying commodities, and also by the still more comfortable effect of reducing their price. The latter consequence is seldom ascribed to commerce, but it does not the less proceed from it. It is the natural result of that progressive augmentation of capital, division of labour, and improvement of machinery, which never fail to accompany an advancing traffic. That rise of prices which of late years has been so remarkable, and which, to hasty observation, seems the consequence of commerce, is in reality produced by very different causes, viz. war, taxes, and the substitution, in various countries, of paper money for coin.

The increased value of land as a permanent property, is denoted by the increase of the number of years' purchase for which it sells. Two centuries ago we had made little progress in trade; the rate of interest was 10 per cent. and the sale-price of land was only ten or twelve years purchase. One century ago, our progress in trade had been considerable; the rate of interest was reduced to 6 per cent. and the sale price of land raised to twenty years' purchase. At present, in consequence of a farther progress in trade, the sale price of land is nearly thirty years' purchase.

Having thus explained the difference between money rent and real rent, and having shewn how greatly the latter is promoted by the prosperity of trade, our next object is to prove, that our corn laws tend to raise money rent only, and have no effect on real rent.

The price of food regulates, directly or indirectly, the price of all other things. This is proved as follows: The component parts of all commodities are three: the raw material—the labourer's wages—the dealer's profit. The price of food regulates that of the raw material, because the raising of such materials, when less profitable than the raising of food, naturally makes room for it. It regulates the labourer's wages, because the wages of the lower ranks are the price of their maintenance. And it regulates the dealer's profit, because that profit is relative to his stock in trade.

the amount of which is determined by the cost of materials and wages,—a cost which we have just shown to be dependent on the cost of food.

The real value of rent, like the real value of every thing else, depends on the quantity of commodities which it will purchase. It is immaterial whether the rent be expended or accumulated, for the rule is applicable to all times, and to all situations. If, therefore, a rise in the money rent of land causes a correspondent rise in the price of all other commodities, the situation of the landlord is the same after the rise as before it. His income, although nominally larger, is of no more real utility to himself in the way of expenditure, nor to his posterity in the way of accumulation. While the supposed effect of our corn laws, therefore, is to enhance the price of one commodity only, (namely corn,) their real effect is an enhancement of all commodities. And this brings us to our last point, namely, the pernicious effects of this enhancement on our landholders as well as on the rest of the country.

If we consider the effects of this enhancement of commodities with reference to our foreign trade, we find, that it lessens our ability to meet the competition of other countries: of countries where the price of labour is not half so high as among us. If we look inwards among ourselves, we shall find, that it contributes to cause a revolution of property to the disadvantage frequently of those who are least able to afford it. This revolution takes place in regard to all money property, whether vested in public or private securities; whether in the funds or in mortgage. All annuitants, in particular, are sufferers by this depreciation. But, to confine ourselves to the consideration of its effects on the landed interest; the discouragement of our foreign trade, and the forced reduction of property at home, are equally pernicious to agriculture. Both these unfortunate circumstances tend to lessen the amount of our capital; to lessen the number of hands whom that capital would employ, and, consequently, the *mouths which would consume the produce of our land.*

It remains that we notice Mr Arthur Young's favourite argument for our present system of corn laws. Without a direct interference by government for the regulation of prices, particularly for preventing them from being greatly lowered by importation, the farmer, he says, would be exposed to frequent discouragement, and would fail in raising the quantity required for our ordinary consumption. In a favourable year, he adds, our prices are low of themselves; in an unfavourable one, we should render them low if we permitted importation; in consequence of which, the farmer would be prevented from sowing extensively, and from carrying improvements into effect; so that, in the long run, a deficiency would take place in the growth, and the country at large would suffer for it.—There are, however, several important considerations in opposition to this opinion of Mr Young. In our climate, under a good system of husbandry, there is little hazard of a *general* failure of the crop. Of our various sorts of grain, several are benefited by that weather which proves injurious to others. In respect to situation, too, the early counties of the south may succeed in securing their harvest, although the autumn may become so wet as to damage the corn in the north. Here we perceive a balance of inequalities operating in counteraction of each other, and, consequently, requiring little aid from the interference of government. Next, as to exempting the farmer from any great or unreasonable fall of price consequent on importation, it is to be observed, that corn is a very bulky commodity; that the freight, insurance, and shipping charges, form of themselves so many distinct taxes on import; and, moreover, that the quality of the grain is more or less liable to deterioration from water carriage. All these circumstances are in favour of the home farmer. They have the practical effect of rendering 60s. a quarter in Britain, a price of no greater benefit to the foreigner than 45s. or 50s. in his own country. Nor is there the most distant prospect of our home growth exceeding our consumption, so as to deprive the British farmer of this important relative advantage. We seem to be already too populous for the productiveness of our soil, and, to judge from the late returns, our population bids fair to go on in a quicker ratio than our improvements in husbandry. The result of these various observations is, that the corn trade may, like any other, be safely left to itself. In this, as in other products, the policy of merchants will provide a remedy for the inequality of the seasons. Sugar, like corn, is dependent on contingencies of weather; yet nobody recommends that government should pass laws, with a view of keeping the sugar market on a level. Merchants, we know, will buy up the article when it falls to a low rate, and, keeping it in store for a time, will bring it to market when the price has become such as to afford a profit. In thus prosecuting his own interest, the sugar-dealer constitutes himself an effectual guardian of that of the public. The case of corn is parallel, and why may it not be left, with equal confidence, to the arrangements of the dealers in corn? The article admits, with due precaution, of being kept from season to season, and it is evidently the interest of the holder to keep back his stock while it is cheap, and to bring it forward when dear—that is, exactly at the time it is wanted. Instead, therefore, of desiring any interference from government, we should merely wish for a final abrogation of the absurd laws against the freedom of corn purchases, or, to borrow the technical terms, against forestalling, regrating, and ingrossing.

The act of 1791, professing to favour the importation and warehousing of foreign corn, permits the same to be landed, but imposes on it when brought forward for home consumption a duty of 2s. 6d. a quarter, in addition to whatever other duties may be payable at the time. Here we have an example of the obstacles placed in the way of the free trade of the corn dealers. The public is under a singular error in suspecting this class of entering into combinations for enhancing grain; for the fact is, that they are often buyers as well as sellers; and in no part of the mercantile body does there exist a greater diversity of opinion. Nor ought we to desire a diminution of the capital employed in the corn trade, when we are apprised that our usual stock, previously to the coming in of a new crop, is equal to only three months consumption, one half of which, at least, is necessary for seed.

It affords some comfort, among the errors which still exist as to the corn business, that the impolicy of small farms is pretty generally acknowledged. These petty occupancies were accompanied by a want of economy both in animal and human labour, while nothing could be less favourable to the advancement of agricultural skill. It is a curious fact, that a century ago, in consequence of our cattle having little other pasture than wastes and commons, the lambs, sheep, and calves, weighed little more than a third, and the oxen considerably less than half of what they weigh at present. It is not generally known that the city of London constructed granaries first at Leadenhall, and afterwards in Bridewell; the former in the beginning of the 15th century, the latter in the course of the 16th. Such deposits may now be safely left to the care of individuals; and one of the greatest blessings attendant on the increased intercourse of nations, in recent ages, is the prevention, as it may be termed, of the occurrence of famine. The stock of one quarter of the world is now so readily transferred to another, that "scarcity and high prices" constitute the extent of an evil, which in former days went the length of absolute privation. Amid all the complicated disadvantages of war and deficient crops, the present age has seen no distress equal to that which afflicted the kingdom in the latter years of Elizabeth.

Among the writers on the side of the corn law system, Mr Dirom, author of the "*Inquiry into the Corn Laws and Corn Trade*," occupies a prominent place. He has been indefatigable in collecting the substance of our various statutes, and in bringing forward the arguments which appear to him to support the plan of bounty on the export of our own, and of a duty on the import of foreign corn. A similar policy is recommended throughout the voluminous labours of Arthur Young. A later writer, on the same side of the question, Mr Mackie, author of "*Letters on the Corn Laws*," directing his attention to the depreciation of money, maintains, that it has been so rapid, that agriculture has derived little protection from the limits prescribed in our late parliamentary regulations. His opponents, on the other hand, would be apt to argue that this fall in money has been the cause of preventing mischief from government interference.

The tenets of the political economists in respect to the corn trade, were distinctly brought forward by Dr Smith; and, in the present day, repeatedly enforced in periodical publications. One of the few practical men who has followed, though not completely, the same course, is Mr Comber, a corn merchant, and author of a late "*Inquiry into the State of National Subsistence*." A small, but very argumentative tract, on the same side, was published in London in 1804, under the title of "*An Essay on the Impolicy of a Bounty on the Exportation of Corn*." (χ)

CORNEA. See Eye, Optics, and Surgery.

CORNEILLE, Pierre, an eminent poet, to whom France is indebted for the first and most essential improvements of her drama. This celebrated name creates more interest in British minds than that of any other foreign poet, because it has been more connected with the rivalship which, in arts as well as arms, has so long subsisted between France and England. In the struggle for predominance which adjoining nations never fail to maintain, the people of each are naturally disposed to prefer the genius which their countrymen have displayed; and by defending their preference on the principles of general taste, to resolve that of their opponents into local prejudice. In this manner, the dispute respecting the comparative superiority of their national dramatists, has been conducted by French and English authors; and whenever an appeal is made by the latter to the productions of Shakespeare, as decisive of victory, those of Corneille are uniformly selected by the former, as supplying more than a counterpoise. In this department, therefore, the contest is, in some measure, reduced to a single combat of the leaders, and the triumph of either champion appears, by a tacit covenant, to secure the dramatic pre-eminence of his nation.

Corneille was born at Rouen, on the 6th of June 1606, eleven years before the death of Shakespeare, and thirty-three before the birth of Racine. His father held the office of warden of the rivers and forests in the vicounty of Rouen, and as a recompence for the services which he had rendered to the crown, received letters of nobility from Louis XIII. Peter, his eldest son, was educated by the Jesuits, and a sense of the benefits which he had derived from the care of that learned and laborious society, inspired him, through life, with the warmest gratitude and reverence for its members. Being called to the bar, he began to practise with little satisfaction or success, and acted for some time as advocate-general in one of the courts of his native city. But though his outset was misdirected, the first impulse of his tender passions turned his genius into its natural path. Perceiving that he had captivated the affections of a young woman, when introduced to her by one of his companions, who was her lover, the incident dwelt so strongly on his mind, that he made it the ground-work of a dramatic essay, which was represented under the title of *Melite*, in 1625, when the writer was only nineteen. Part of the profits which it produced are said to have been received by Hardy, the immediate predecessor of Corneille in dramatic poetry, according to a contract with the managers, by which Hardy engaged to furnish them with new pieces, on condition that he shared the produce of all which were accepted for representation from the pen of others. Though this early attempt of Corneille was much inferior to the productions of his ripe and practised genius, its success with the public, which was so great as to occasion the formation of a new company of comedians, and the delight he had felt in its composition, induced him to persevere in writing for the stage. Corneille was prevented, by the diffidence of youth, from the boldness of forming a style for himself in his first performance. He contented himself with imitating the dramatic practice which then prevailed; and *Melite*, therefore, originally contained many of those indelicacies of sentiment, and even of action, which his predecessors had thought requisite to the popularity of a play, but which he afterwards corrected. This piece being chiefly censured for want of incident, in the next, which was *Clitandre*, he erred in the opposite extreme, but settled at a proper medium in his subsequent attempts. The earliest of these were principally comedies, by which he gained considerable reputation; but having gone to visit M. de Chalon at Rouen, the latter, after a compliment to his genius, told him that in comedy he could expect only a slight and temporary fame, and exhorted him to study the Spanish drama, where he would find subjects which, under management like his, might in tragedy produce the most signal effects. His friend undertook to teach him the Spanish language, and in the mean time to translate for him some passages of Guillelmo de Castro, with which Corneille was so much delighted, that he soon after began his celebrated *Le Cid*, the plot of which that author supplied. The appearance of this piece in 1637 formed an epoch in the history of the French drama, and carried it forward by one of those instantaneous advances to excellence, which are accomplished only by genius of the highest order. The instant and universal success of *Le Cid*, and its superiority to all former specimens of the French drama, inflamed the jealousy of minor writers, and converted into attempts at censure the disposition which they had shewn to applaud its author, when he appeared to rise only a little above the ordinary level. Even the celebrated Richelieu, whose ravenous ambition sought to add poetical to political distinction, could not conceal the chagrin with which he saw his dramatic efforts outshone; and did not blush to engage a host of critics to depreciate a work, which he could not prevent himself from both admiring and rewarding. He thus presented the singular spectacle of a man, who was in some respects the greatest of his age, sinking to unexampled littleness in his feelings of literary rivalship, and labouring insidiously to make the public reverse his own judgment, and condemn him for bestowing rewards, the justice of which was powerfully attested by the envy which prompted so mean and inconsistent a conduct. Of all the attacks upon *Le Cid*, the most able was that of Scudery, who proposed that the French Academy should be umpires in the controversy; and Corneille, probably from the fear of offending so powerful a benefactor as Richelieu, having consented to this reference, the opinion of the Academy was delivered, with admirable address, in a critique which gratified the Cardinal, by admitting the faults of the piece; and the public, by touching them with lenity, occasionally rising into admiration. We have reason to suspect that Richelieu was aided in this disgraceful intrigue by another person of high rank, from the following expression of Corneille, in a letter to one of his friends, concerning the success of *Horace*, which was the next piece he produced; *Horace*, he says, *fut condamné par les Duumvirs, mais il fut absout par le peuple.* The poet, indeed, could not fail to resent the contemptible conduct of his patron, though prudence made him dissemble his indignation, as he acknowledged, after the death of Richelieu, in the following epigram:

Qu'on parle mal ou bien du fameux Cardinal,
Ma prose ni mes vers n'en diront jamais rien;
Il m'a fait trop de bien pour en dire du mal,
Il m'a fait trop de mal pour en dire du bien.

Notwithstanding the powerful efforts to depreciate *Le Cid*, its popularity continued such as to create the proverbial phrase, when the singular perfection of any thing was to be strongly expressed, *Il est beau comme le Cid.* Animated by success, Corneille became a diligent writer for the theatre, and the enumeration of his works is therefore the best record of his life. In the following list we subjoin to each play the date of its first representation. *Melite*, 1625; *Clitandre*, 1632; *La Veuve*, 1634. To the first edition of this play were subjoined complimentary verses addressed to the author by *Boisrobert, Douville, du Ryer, Scudery*, and others. *La Galene du Palais, La Suivante, La Place Royale*, and *Le Cid*, 1637; *Medée* and *L'Illusion Comique*, 1639; *Horace*, 1641; *Cinna*, 1643; *Polyeucte Le Menteur*, and *La Mort de Pompée*, 1644; *La Suite du Menteur*, 1645; *Theodore*, 1646; *Rodogune* and *Heraclius*, 1647. It was in this year Corneille became a member of the French Academy. *D. Sanche d'Arragon*, 1650; *Andromede* and *Nicomede*, 1651; *Pertharite*, 1651. This piece was so much disapproved of that its author became disgusted, and for some years wrote nothing for the theatre. *Œdipe*, 1659; *La Toison d'Or*, 1661; *Sertorius*, 1662; *Sophonisbe*, 1663; *Othon*, 1665; *Agesilaus*, 1666. At this period Racine made his appearance as a dramatic poet, and Corneille perceived a considerable alienation of the public preference, which he had hitherto monopolized. *Attila*, 1668; *Tite et Berenice*, 1671; *Pulcheria*, 1673; and *Surena*, 1675. The admiration which Corneille had procured by *Le Cid* was sustained, and even augmented, by a few of his subsequent productions, such as *Cinna, Horace*, and especially *Polyeucte*; though his genius was so unequal, that most of the rest did not exceed, and some did not reach mediocrity. Such, at least, is the opinion of Voltaire, who says, that only six or seven of Corneille's dramas continue to be represented, and that pardon must be gained by these for above twenty, which, except in a few passages, are the worst of the French plays, not only in point of style, but from barrenness of intrigue, misplaced amours, and wire-drawn dialogues. *Theodore* and *Don Sanche* having been coldly received, and *Pertharite* absolutely damned, their author embraced, from chagrin as has been already noticed, and intimated in the preface to *Pertharite*, a resolution, for which he gave his age as the ostensible reason, of ceasing to write for the theatre. He then took the opportunity of engaging in religious studies, to which he had always been disposed, and translated into verse the treatise of Thomas a Kempis *de imitatione Christi*. This translation, chiefly we presume from the name of the writer, became so popular as to pass through 32 editions; a fact, says Voltaire, as difficult to believe, as it is to read the work. After six years of self-denial, Corneille, was prevailed upon by M. Fouquet, then minister of the finances, to return to the drama, and made a trial of his powers in the *Œdipe*, of which the subject was suggested by his adviser. This piece being received with applause, he continued to indulge his natural bias to dramatic composition, till his 70th year. On his reconciliation with the theatre, he found the public warmly prepossessed in favour of the new character which had been communicated to the drama by Racine. The latter excelling in tenderness and in the plaintive and elegant expression of sensibility, made love the master-passion in most of his plots; but Corneille, conceiving this to be a descent from dramatic dignity, and naturally preferring the style in which he was conscious of excellence, selected fables, where patriotism, valour, and other stern and stately virtues, were the principles of action. The change of taste which his rival had created, by leading him to examine and deny its justice, confirmed his original determination; and instead of following the popular example of Racine, he seems to have rebuked its admirers, by the subjects which he chose for the last series of his productions, and especially by challenging their favour to an exhibition of the savage and ferocious energies of Attila, the barbarian. The people, however, did not relish this defiance; and though the remains of former favour rendered them indulgent to his faults, the epithet of "old *Corneille*," by which he began to be distinguished, proves that, even in his lifetime, they had consigned him to the class of obsolete and unfashionable poets. On finally renouncing the theatre, Corneille employed all his thoughts in preparing himself to die like a Christian; and for this pious duty he was allowed more leisure than he had a title to expect, as his death did not happen till the 1st October 1684, when he was in his 79th year. The respect which he enjoyed had previously been shewn, by his election to the Deanry of the French Academy; and his *eloge* was pronounced before that dignified body, by his amiable and admirable dramatic rival. Many other encomiums were contributed by his eminent contemporaries; and if *laudari a laudato viro* be the best attestation of worth, if excellence may be estimated from the excellence of those by whom it is praised, what posthumous honour can be greater than his of whom the biographer was Fontenelle, and the eulogist Racine?

In the private character of Corneille there seems to have been nothing extraordinary. From his writings we may infer that he was a scholar, and that he was abundantly skilled in the literature and history of the ancients. He seems to have been partial to the Romans, whose lofty sentiments and masculine rigidity of heroism he took a peculiar delight in conceiving, and clothing with poetical expression. Seneca, Lucan, and Statius, whose two first Thebaids he translated, are said to have been his favourite authors, which shews that he was less offended with the occasional affectation than with the absence of that stoical grandeur of thought, which these writers seem perpetually straining their genius to produce. Corneille was also well acquainted with the *belles lettres* and criticism; but all his studies were made subservient to his ambition of dramatic excellence. In person he was of a good size; in countenance agreeable and strongly marked, especially by the vivacity of his eye; in manner plain and simple; and in dress unaffected or even slovenly. To elocution he had few pretensions, and in reciting his own verses, though emphatic, he was ungraceful. In conversation, he was neither elegant nor interesting, and disappointed the expectations which might have been formed from his writings. He was one of that high order of poets, whose faculties are elevated at times to a measure of exertion too violent to endure, and in whom extraordinary activity requires corresponding repose. He was an example therefore of that unaccountable disparity, which Professor Stewart had remarked in the case of other poets, between their general powers, and the inspirations of their more favoured moments. But though the conversation of Corneille had few attractions, his dramatic celebrity was sufficient to render his society an object of eager desire in the most polished circles. In France, at that period, the most fashionable manners were supposed to include a certain portion of literary taste. Where this did not exist, it was pretended, and the pretence maintained by a shew of enthusiastic admiration of men of genius, who were thus secured from that neglect to which they are destined in countries where no such fashion prevails. Corneille, therefore, as the father of the drama, and the boast of the nation, had his choice of society, and the most illustrious assemblies of *noblesse* felt themselves receiving, rather than conferring, distinction by his presence, which they thought would be interpreted into an authentic acknowledgment that they possessed, not only the titles, but the accomplishments of their rank. His pieces were frequently read before representation at the *Hotel de Rambouillet*, to a circle of courtly critics; and we learn from Madame Sevigné that, even in his old age, he continued to gratify the celebrated characters of the day, with the first communication of his works. "Nothing," says that accomplished lady, "will ever come up to the enchanting passages, we meet with in Corneille. He read us, the other day, at M. de la Rochefaucauld's, a piece of his which shewed what he had once been. It cost me many tears." (Letter 124.) "Corneille," she says again, "has read a piece of his to amuse Cardinal de Retz. It reminds me greatly of the beauties of the ancients." (Letter 139.) Such was the veneration which Corneille enjoyed, and such the pleasure he could impart, at an age when the power of giving pleasure is generally extinct. In his moral character he seems to have been unexceptionable, and to have escaped the singularities in which genius too frequently thinks itself privileged to indulge. He was an exemplary husband, father, and relation; and the keen sensibility, which enlivened his representation of the heroic passions, gave him a warmth of manner, in asserting his independence, which approached occasionally to roughness; for he had from nature a loftiness of spirit, and disdain of supple servility, which, in his Roman characters, enabled him to paint from himself. He had a rooted aversion to business, in consequence of which, though he received considerable sums for his writings, he never was rich. His means of subsistence were derived chiefly from his pen; and in his latter years, from a pension granted by Louis XIV. This was, at one time, about to be withdrawn, which Boileau prevented, by offering to relinquish his own pension in favour of the venerable dramatist This offer, so honourable to Corneille, does no less honour to Boileau, who, though warmly attached to Racine, was ready to have made so great a sacrifice for the rival of his friend. Corneille was deterred, both by his taste and by his principles of religion, from copying, except in his first attempts, the licentiousness of his predecessors; and the French stage is thus indebted to him for exalting its character, both by the moral and poetical superiority of his compositions

In considering his genius, its extent must be estimated from the best of his works, and from the state at which the art of poetry had arrived, when he began to write. The last criterion is peculiarly important; for it often happens, in art as well as science, that the previous approaches to some capital invention have been so close, as to entitle its author to the praise, rather of a fortune, than of an ability superior to his predecessors. In each step there may have been equal difficulty; but to him who makes the last, by which some augmentation is produced to human enjoyment, the triumph is reserved. Where excellence, therefore, has been attained without the help of such preparatory approximations, a mental effort must have been made, proportioned to this defect; and Homer, Milton, and Corneille, may claim a double share of admiration, as having reached, in the earliest age of their national poetry, a perfection which none of their successors have maintained. Before the appearance of Corneille, the French drama was in so rude a state, that the names of Jodelle, Garnier, and Hardy, who immediately preceded him, are preserved chiefly to illustrate the extent and rapidity of his improvements. He first conceived the idea of following the rules and examples of the ancients, and of applying them to a greater variety of subjects; and even in his initiatory attempts, this conception was executed with success. Comedies, consisting chiefly of farcical mistakes, without the slightest attention to manners, character, or plot, and tragedies no less unskilful in design than flat in composition, our author superseded by productions, which, addressing the most universal feelings of nature, were equally interesting to the highest and the lowest of the auditors. Corneille seems to have delighted in the conflict of the most powerful passions; and when he gives the triumph to those which, in ordinary characters, are weakest,—when he makes the desire of avenging a departed parent overcome the most ardent affection for a living lover,—he shews a confidence in his genius, which was justified by success. A drama is the relation, in dialogue, of some extraordinary occurrence.

by which minds of singular force are placed in situations which call all their energies into full exertion; and it is partly from a natural curiosity to see how human beings will acquit themselves in the most trying and unusual circumstances, that the eager attendance on tragical spectacles, both real and fictitious, must be explained. Corneille excelled in conceiving characters of the most exalted heroism, and in making them express their majestic sentiments in language of corresponding magnificence. It is to be doubted, however, whether he does not impair our sympathy with some of his heroes, from carrying their magnanimity beyond what is warranted by the imperfect nature of which we are conscious, as we sympathize chiefly with conduct which we suppose might, under similar circumstances, have been our own. The sententious grandeur, too, and the antithetical brevity, in which his speakers couch their lofty ideas, may sometimes appear more like the language of laborious study, than the artless and sudden expression of vehement emotion. His countrymen, however, will perhaps not allow these objections, as they are still so prone to the imitation of the ancient sentimental apothegm, and so prompt in pointing it with felicity, that what a foreigner conceives to be too artificial, may be a just representation of human nature, under the peculiar modification which it has received from local character: and critics of a different nation should remember, that it is not from the study of *human* nature only, but of *French* nature also, that mankind will be delineated by a dramatist of France. Corneille is charged with slovenly versification, and metrical negligence; and he is certainly far from equalling the delicate suavity of Racine, or the minute exactness of Boileau. This may, however, be partly explained by the priority of his appearance, in an age when the improvements of style were singularly rapid. The sublimity of those passages which he frequently produced, would appear to their author, as they did to others his contemporaries, an apology for the imperfection of others in which he took less interest, because he had been less successful. "The piece," says Madame Sevigné, speaking of Racine's Bajazet, "has doubtless its beauties, but none of those strokes, that, like Corneille's, make one tremble. Let us forgive the bad lines we meet with in the latter, for the sake of those divine sallies that so often transport us, and bid defiance to imitation."

In comparing Corneille with Shakespeare, we must recollect, not only that the latter was born half a century before the former, but also that, even if his appearance had been deferred to the end of that period, the art of composition was more advanced in France than in England during the age of Corneille. In testimony of this, we have to remark, that, in every country, the improvement of style generally begins in its poetry, and is slowly communicated to its prose, and that the prose writing of Corneille differs less than that of his English contemporaries from the present language of their respective countries. To this we must add, that Corneille had all the aid of a classical education, of which Shakespeare was comparatively destitute. Under these disadvantages, though the latter be inferior in critical disposition and design, he is surpassed by none in the successful boldness of his portraiture of character, in luxuriance of invention, in combining novelty of conception with fidelity to nature, and in the irresistible power with which he absorbs the attention, and agitates the passions. The favourite heroes of Corneille display a magnanimity, of which the probability is perhaps impaired by our sense of human weakness; while those of Shakespeare excite a keener sympathy, from the leaven of infirmity which is mingled with their virtues. The inflexible heroism of the former is a more obvious and manageable idea, than the intricate and interesting struggle of sensibility and indecision in the character of Hamlet, or the blaze of regal virtue, emerging from the eclipse of early dissipation, in that of Henry the Fifth. Corneille exhibits nothing in tragedy, at once so extraordinary and so natural, as the progressive wickedness of Richard or Macbeth; and in comedy, nothing so amusing, yet so conceivable, as the mirthful profligacy of Falstaff, or the engaging peculiarities of Fluellen. Corneille sustains the grand but simple characters which his mind had created, through a short transaction, with masterly skill: while those of Shakespeare, though of a more delicate and singular mechanism, are conducted, with apparent ease, through a long succession of situations, by which all their involutions are artfully unfolded. Corneille proceeds, with a straight majestic step, on even ground; but Shakespeare delights to force his way amid tortuosities and obstructions, and to surmount them all. Corneille has been said to represent men as they should be, and Racine as they are; but the last of these encomiums belongs with more propriety to Shakespeare. Corneille seems to have studied human character in books or in reflection, and Shakespeare in the experience and observation of real life. The sentiments with which Corneille supplies his interlocutors are splendid and impressive, but appear occasionally couched in a style too rhetorical for the sudden effusions of unstudied dialogue; while those of Shakespeare grow so spontaneously from the occasion, and drop from the speaker with such prompt felicity, that we imagine the speech would have been incomplete without them. In the conduct of their fables, Corneille is betrayed into errors by his adherence to the unities, and Shakespeare by his neglect of them. The former crowds his incidents into too narrow a space; and the latter, in lengthening the intervals between them, forgets that they were to be accommodated to dramatic representation. Both poets excel in bringing their characters into situations, which create the most violent conflict of the passions; yet the struggle of Cinna between loyalty and love, or of Polyeuctes between religious enthusiasm and conjugal affection, is at least not superior to that between the remorse and ambition of Macbeth, or the jealousy and tenderness of Othello. Corneille sometimes mistakes the description which would suit a spectator, for the natural expression of a passion in one who speaks under its immediate impulse; while in Shakespeare, the passions are recognised in the agitated accents of their victim, as readily as the existence of pain is inferred from the cry of the sufferer. In language, Corneille must be allowed a negative preference; as he never descends to the quibbles and conceits to which Shakespeare could not, for ten lines together, resist the temptation; but the positive pre-eminence of the latter might be demonstrated by innumerable passages, which his rival has never equalled. In the invention of imagery, Corneille is more correct, and Shakespeare more original. No simile of the former is at once so touching, so graceful, and so new, as that by which a female concealing her love, is painted by the latter:

> "She sate like Patience on a monument
> Smiling at Grief."

There is one department in which no comparison can be stated, as it is unattempted by Corneille, but in which it seems hardly possible that Shakespeare should have been surpassed. We allude to the invention of preternatural agents, or what, in epic composition, has been termed *machinery*. When Shakespeare wrote, the public mind was in that state of juvenility, which delights in ascribing to miraculous powers those appearances which its rude philosophy is unable to explain. This popular predilection Shakespeare was obliged to indulge; but he did so in a manner which, instead of debasing, bestows additional interest and ornament on his productions. His fancy gives a new character to the ideal beings of the vulgar mythology, and enriches it with others of his own creation; nor do we think the ingenuity of Corneille could have produced such a visionary offspring as the fairies and the ghosts, or the Ariel and Caliban of Shakespeare. From this comparison, we hope to escape the charge of a childish nationality, if we conclude with assigning the palm of genius to Shakespeare, and that of art to Corneille; and with admiring the varied and extensive powers brought into action by the former, and the scientific skill with which a smaller portion is disciplined and arrayed by the latter. (W)

CORNET STOP, in Music, is the name of a compound set of pipes on the organ; in the use of which, each finger-key acts upon and occasions five different pipes to sound at the same time, viz. one which is tuned unison (I) with the proper note of such finger-key, (and with the same note of the diapason stop), another is tuned a true IIIrd above this, another a true Vth, another an VIIIth, and the uppermost a true XVIIth above the lowest. This stop is usually, in church organs, only a *treble* or *half-stop*; that is, its lowest note is the tenor-cliff C, or at most the bass-cliff F: and from being most frequently used (with the diapason) in interludes between the verses, or in giving out the psalms, in the English churches; some organ concerto players have also used it, and hence it is also called a *solo* stop, as well as because it is not used in chorus or the full organ for want of a bass, unless that the SESQUIALTERA, another compound stop, or such organ, is divided into two parts at C or F, so that the lower part can be drawn along with the cornet, and its own upper half omitted for the sake of variety. Dr Smith remarks, that the best tuning cannot wholly prevent these very compound stops from battering the ears with a constant rattling noise of beats. See COMPOUND *Stops*. (e)

CORNUTIA, a genus of plants of the class Didynamia, and order Angiospermia. See BOTANY, p. 254.

CORNWALL, is the county which forms the south-western extremity of Great Britain. The Land's-end, which is its western termination, lies in latitude 50° 5′ north, and in longitude 6° 0′ west. Its most southern point is the Lizard, which lies in latitude 49° 57′ 30″ north, and in longitude 5° 15′ west. This county is surrounded every where by the sea, except on its eastern side, where it is separated from Devonshire by the river Tamar, and an artificial boundary of a few miles in length at its northern extremity. On the south it is washed by the British channel, and on the north by the Bristol channel, so that it forms nearly a complete island. Its form is nearly that of a cornucopiæ, and, from its resemblance to a horn, it seems to have derived its original name in the British language, *cernyn*, which signifies a horn or promontory. The north-eastern angle of the parish of Morvinstow, near the source of the Tamar, to the east, and the Land's-end, in the parish of Sennan, to the west, are the two most distant points of Cornwall: measured in this direction, in a line nearly south-west and north-east, its length is seventy-eight miles and a half. Its widest part, from Morvinstow on the north, to the Ramhead on the south, is rather more than forty-three miles; but this width rapidly contracts, and its medium width, between Padstow on the north, and Fowey on the south, is about eighteen miles: if measured from Mounts-bay on the south, to Heyle river on the north, its width does not exceed four miles. Its circumference is estimated at 210 miles; and, according to Martyn's map, which was drawn from an actual survey, the whole area contains 758,484 statute acres, or 1185 square miles. It is divided into the following hundreds: Shalton, east, west; Lesneeoth, Trigg, Pyder, Powder, Kirrier, and Penwith.

Climate.

The climate of Cornwall is damp and uncertain: the winters are, in general, mild and open, and the summers cool and cloudy. For nearly three fourths of the year, the wind blows from the intermediate points between the south and the west, and consequently sweeping over a large tract of the Atlantic ocean, they bring vast bodies of clouds, which being broken by the hills, descend in frequent showers. It is observed, however, that the rains are not near so violent in this county as in many other parts of England; and the moisture of the climate is as much owing to the fogs as to the showers that fall. The winds are often changing from one quarter to another with great violence; and this circumstance, though it increases the mutability of the weather, prevents those stagnations of damp air which are so prejudicial in some wet countries. On the north side of the county, the north-west winds are extremely violent and desolating, but they are generally dry, and bring fair weather. In consequence of the saltness of the atmosphere, and the violence of the winds, the most hardy trees are very stinted and unhealthy in their appearance near the sea-shore: and the salt spray of the sea is sometimes driven with such violence as to destroy the crops of wheat and turnips. Most of the trees and shrubs lean to the eastward, and have the appearance of being clipped by the gardener's shears. Notwithstanding the unfavourable nature of the climate of Cornwall, its southern latitude, and the prevalence of the south-west winds, give it such a degree of mildness, that geraniums, myrtles, and other tender shrubs, thrive uncommonly well in the open air. The surface of this county is, with very few exceptions, very unequal. The ridge of bare and rugged hills which runs through its whole length, is however intersected and broken by some picturesque and fertile valleys. The highest hills are Carradon, Roughter, Brown Willy, and Heresborough, but none of them deserve the name of mountains. The height of Brown Willy above the level of the sea at low water, according to Major Mudge, is 1368 feet.

Soil.

The soils of Cornwall are of three descriptions: the black growan, or gravelly; the shelfy, or slaty; and the loams. The first consists of a light mossy black earth, intermixed with small particles of granite, cal-

Cornwall. led *growan*, from *grow*, a Cornish word, signifying gravel: this soil is found principally in the western parts of the county. The slaty soil is the most abundant: it is formed of schistose matter, mixed with loam. The pure loamy soils are of no considerable extent; they are found principally on the low grounds, declivities, and the banks of the rivers. From this description of the soil and climate of Cornwall, it will appear that it is one of the least inviting of the English counties. The

Rivers. rivers in Cornwall are all small: the principal are the Tamar, and the Camel: the former rises on the summit of a moor in the parish of Morvinstow; it follows a southern direction, with very little variation, for nearly 40 miles, when it falls into the harbour of Hamoaze. The Camel, which is the largest river on the north coast, has two sources, one near Camelford, the other near Roughter: The streams join below Kea-bridge, and from Wade-bridge to Padstow harbour the river is navigable. Besides these rivers, there are the Lynher, the Loo, the Fawy, and the Fal. At the mouth of the Loo, there is a curious fact; the river forms a kind of reservoir, at a little distance from the sea, from which the water runs into the sea by a subterraneous passage: at no time of the year is the water in this pool salt, or even brackish.

Property, leases, &c. Property is very much divided in Cornwall, so that there are no estates of any considerable size. The tenure of land, for the most part, is freehold; some is held of ecclesiastical corporations; and the ancient duchy land is held under the Duke of Cornwall, as copyhold in fee, subset to a small annual rent. Formerly leases were often granted for lives, for a term of 99 years, determinable on the death of the longest liver of three lives; the landlord, however, consenting to add a new life, on the death of one of them, on the payment of a fine of from 14 to 18 years rent. This kind of lease is now on the decrease, except in cases of miners, who enclose patches of the waste land to the westward of Truro, granted to them on the condition that they build a cottage, and pay an annual rent of ten shillings.

Agriculture. In an agricultural point of view, Cornwall presents very little worthy of notice. Its implements are very various, but few of them are peculiar to it. The Cornish waggon, or wain, however, may be recommended, as being extremely well adapted for carrying corn and hay in harvest time. The old Cornish plough is a rude and simple instrument, which still maintains its ground in many parts of the county. In the lower parts of Cornwall, corn is thrashed on *barn boards*, raised above the level of the barn floor, each plank being about the third of an inch from the next to it, so that the grain falls through it, and is not bruised as in the usual manner. In some parts, the wheat is beaten out by women on a barrel, or inclined plane. The term *hedge* is applied to all kinds of mounds or fences, of which there are three sorts; stone hedges, made of coarse slate, which are principally on the western part, and on the sea-coast; earth hedges, capped with stone, &c. on the moors, and in the country round Camelford; and the common hedges, which are most usually met with on the eastern part of the county. Nearly one third of the cultivated land is under the plough: the crops generally grown, are wheat, barley, and oats. The *arena nuda*, which in Cornwall is called *pilez*, is sown in the western district. This grain is smaller than the common oat, and the straw much more delicate, so as to answer for feeding horses and cattle nearly as well as hay: this kind of oat is steamed with potatoes, and used for fattening pigs. The soil and climate of this county are particularly favourable to the growth of potatoes; and a very large portion of the tillage land is annually planted with this valuable root, the cultivation of which is carefully attended to and well understood. The uninclosed waste lands in Cornwall are computed at nearly 200,000 acres, the greatest part of which serves no other purpose than to afford a scanty pasturage to a miserable breed of sheep and goats. The agricultural produce would be much more limited than it actually is in this county, were it not for abundant supplies of three valuable manures, two of which, as almost peculiar to it, deserves to be noticed; these are fish and sea-sand; the third, seaweed, is used in many other parts of the kingdom. Bruised and small pilchards, called "*caff*," are buried in a pile of earth, where they are permitted to lie for some months before they are laid on the ground: sometimes the fish are used alone. The liquor which drains from them while under the process of curing, is also deemed a valuable manure. The sea-sand of Cornwall is found to be very fertilizing, containing in general a great quantity of calcareous matter; and some of it, a slimy earthy matter, called *lig*, or *liggair*, which is applied to potatoes. The sand, which is in the highest estimation, is found near Falmouth; it is frequently carried fifteen miles inland, on horses, mules, or asses, about 2 cwt. called a *seam*, being the burden for each animal. This sand has a more immediate, as well as a more permanent good effect, on the moor-lands, than on the loamy soils, and is therefore very valuable when found in the vicinity of them. It is reckoned that 54,000 cart loads of sand are carried from Padstow harbour alone, and that the expence of land carriage for it, in the whole county, amounts to L. 30,000 per annum. Lime is found only in two places, in the parishes of South Petherwin and Veryan: the Veryan limestone contains a considerable quantity of manganese and oxide of iron, and is more valuable as a cement than as a manure.

Cattle. Few of the native cattle of Cornwall are now in existence; they are very small, of a black colour, short horned, coarse boned, with a large proportion of offal, at the same time very hardy: they have been superseded by the genuine north Devon. The practice of letting cows out to labourers and poor people, is not unusual among the farmers; the hirers have the milk and butter; the farmers the calves. Oxen are much employed in agricultural labour, being worked from three to seven or eight years old, and regularly shod.

Sheep. The native sheep, like the native cattle, have nearly disappeared. Carew, in his Survey of Cornwall published in the beginning of the 17th century, describes them as having little bodies, and coarse fleeces, so as their wool bore no better name than Cornish hair, and hath from all ancientry been transported without paying custom. On the sand hillocks on some parts of the north coast, there is a small compact sheep, the mutton of fine flavour, and the fleece nearly equal to that of the South Down. These sheep have been observed to feed greedily on the small turbinated shells, which come out from the sand, in the mornings and evenings.

Mines. Cornwall is celebrated for its mines, of which there are generally about one hundred of different kinds wrought. Of these, in 1800, when an accurate map of the mines was made by Mr William Phillips, there were 45 of copper, 28 of tin, 18 of copper and tin, 2 of lead, 1 of lead and silver, 1 of copper and silver, 1 of silver, 1 of copper and cobalt, 1 of tin and cobalt, and 1 of

Cornwall. Mines.

antimony; since that time, some mines of manganese have been opened. The copper and tin, either singly or combined, forms at least four fifths of the mines of Cornwall, and are met with near the junction of the granite and grauwacke. Tin, when not combined with copper, generally forms a part of the granite; and often, in this case, wolfram is found in the matrix of the vein. Tin is found combined with sulphuret of lead in the mine of Heavas, in the parish of St Mewan, which is a rare and anomalous occurrence. It is accompanied with arsenical pyrites, copper pyrites, and blende, in the mine of Trerascus and other places. Sulphuret of antimony was formerly worked in different parts of Cornwall, but these workings are now given up. There are two mines of manganese, one on the road from Bodmin to Truro, and the other a mile to the south of Launceston. They are very productive; the one is shipped for Lancashire, where it is used in bleaching cotton. The lead mines are confined to the low parts of the county: galena, in large cubes, is found at Tresearen, united with copper pyrites; at Poldice, mixed with the same and arsenical pyrites; and at Penrose, a rich vein of it opens to the surface. So various are the mineral productions of Cornwall, that, with the exception of platina, mercury, molybdena, tellurium, tantalium, columbium, and cerium, it affords indications of all the other known metals.

Tin and copper.

But the principal mineral products of Cornwall, are tin and copper. These metals are generally found in veins and fissures, which are here called *lodes*; one side of the fissure is sometimes a dense stone, and the other a soft clay. The direction of the fissures is commonly east and west; sometimes they are perpendicular, but more frequently dip to the right or left as they descend. Their course is seldom in a straight line, and it is remarked that their bendings form larger angles in crossing a valley. Tin is found either collected and fixed, or loose and spread about; in the former state, it is either in a lode or in a horizontal layer; or interspersed in panes and small masses. It sometimes happens that a lode which runs perpendicular for several fathoms, suddenly changes into a horizontal layer. Tin, in its dispersed form, is met with either in a pulverised state in separate stones, which are called *shodes*, or in a continued course of such stones; this course is called a *stream*. The Toth stream works were formerly the most considerable and valuable in Cornwall, but they were all washed away by the sea in the year 1801. The Carnon stream works are now the most extensive; they occupy a portion of ground nearly one mile in length, and 300 yards broad; the whole of which space appears to have been gained from the sea. From the nature of the stream works here, and in other parts of Cornwall, there can be little doubt that the accumulations of ore found in them, have been originally true veins, worn down and removed by some cause or other from the place where they were found, and covered by alluvial soil.

As soon as the ore is raised from the mines, it is divided into as many shares as there are lords and adventurers, and these are measured out by barrows, an account of which is kept by a person who notches a stick. Every mine has the right of having her ore distributed on the adjacent fields. Stamping mills are generally erected on the spot where it is pounded; to assist this operation, a rill of water keeps it constantly wet, and it is carried by a small gutter into the *fore pit*, where the heavier particles settle, the lighter ones being carried forward to the *middle pit*, and from that into a third. It is afterwards washed in a large vat, and made sufficiently clean for the smelting house. If the mine is of great extent and importance, the people employed are divided into certain classes: The foreman, or captain as he is called, allots each workman his task, pays them their wages, and keeps the accounts: the underground captains inspect the works in the mine, take care that the ladders, ropes, &c. are in good repair, and overlook all the different objects connected with the working of the mine.

Both the *stream* and *lode* works lie either in *severall* or in *wastrell*, that is, in enclosed pounds, or in commons; in the former, no person can search for tin, without the permission of the lord of the manor; but, in the latter, it is lawful for any man to make trial of his fortune that way, provided he make an acknowledgment of the right of the lord of the manor, by giving him a certain part of the produce, which is called the toll. The *wastrell* works are reckoned among chattels; and when a mine is found in this situation, the discoverer endeavours to ascertain how far it is likely to extend; at the supposed limits, he digs up three turfs; (which is termed *boundary*,) and within these every other person is restrained from searching.

All the tin ores are wrought into metal in the county, and afterwards cast into blocks, from two hundred and three-quarters to three hundred and three-quarters each. Before these can be exposed to sale, they must be assayed by the officers appointed by the duke, and stamped by a hammer with the duchy seal: this is denominated *coining the tin*. The original stannary towns to which the tin was carried to be coined, were Launceston, Lostwythiel, Truro, and Helston; but, in the reign of Charles II. Penzance was added, for the convenience of the miners in the western part of the county. The coinages are held regularly four times each year, at Lady Day, Mid-summer, Michaelmas, and Christmas. The annual produce of the tin mines varies from 25,000 to 30,000 blocks; the value of each block is, on an average, generally about L.10.

It is generally supposed, that the tin mines of Cornwall were wrought, or visited by the Phœnicians and Greeks: the Romans also probably did not neglect them, while they were in possession of this island. During the dominion of the Saxons, they were neglected; and even in the reign of King John, the *tin farm* amounted only to 100 merks. At this period, the Jews had the sole management of them. In the 18th of Edward I. the mines were again neglected, in consequence of that monarch banishing the Jews. Soon afterwards, a charter was granted to the gentlemen of Blackmoor, by Edmund Earl of Cornwall, granting them several privileges in the working and management of the tin mines; and, in consideration of these privileges, they bound themselves to pay to him and his successors, Earls of Cornwall, the sum of 4s. for every hundred weight of white tin; and on this occasion the stannary towns were first fixed. This charter was confirmed in the 33d of Edward I. The tinners of Cornwall were made a distinct body from those of Devonshire, and the privilege of having a coinage both at Mid-summer and Michaelmas was granted them. Several acts were afterwards passed, confirming and enlarging these privileges: by them the society of tinners was divided into four parts, under the superintendence of one warden, with an appeal from his decision to the Duke of Cornwall. The lord warden is empowered and instructed to appoint a vice-warden, to determine all stannary disputes every month. Stannary courts are also directed to be held by four stewards, appointed by the lord warden, where causes are decided by juries of six persons.

As the copper mines of Cornwall, though numerous and productive, are not peculiar to it, they do not require particular description. We shall, therefore, proceed to notice those appearances and productions of this county, which are most interesting to the geologist, the mineralogist, the botanist, and the natural historian. This county may be considered as formed of a chain of low mountains, stretching from E.N.E. to W.S.W. The central and highest part of this chain is granite, extending into a narrow mountain plain at the north-eastern extremity, and, at the other extremity, gradually contracting into a ridge; on each side of the granite, grauwacke is found: both sides of this chain have nearly the same inclination, the rivers on the one side running into the British, and on the other into the Bristol Channel. The grauwacke formation occupies a very considerable extent in Cornwall: on the southern side of the chain, it is found from the mouth of the Hamoaze to that of the Huel, a space of about 40 miles from east to west. The Cornish miners give the name of killas to a variety of grauwacke slate, which is very abundant in this county, which is smooth to the touch, though not unctuous; the colour varying from dark-grey to white; the lustre silvery, and the structure schistose: it is very rich in ore. The grauwacke continues uninterrupted from Lynhercreek to the north, till we approach Kelt-hill, near Callington, where its termination is indicated, by the quantities of quartz lying on the road. In the neighbourhood of Kelt-hill, an adventitious mass of tourmaline, of a cylindrical form, has been found, which the Count de Bournon considers a new variety of form. In the neighbourhood of St Stephen's church, the *killas*, or grauwacke slate, passes into the slate of common grauwacke; and its termination, on this side, is indicated, by its being stained with oxide of iron, and mixed with numerous veins and pebbles of quartz. Near this place, decomposed granite, in the state of *kaolin*, or China-stone, as it is here called, is found: its qualities were accidentally discovered about 50 years ago, by a gentleman who was present at the founding of some bells at Fowey, and noticed the appearance of some of the earth, which had been contained in the mould. Great quantities of kaolin are sent by sea from Charlestown, for the use of the Worcestershire and Staffordshire potteries. It has also been manufactured at Truro, into retorts and crucibles, of an excellent nature for resisting fire. The next formation of importance, which succeeds the grauwacke in Cornwall, is the serpentine, which stretches from the neighbourhood of Treelevor, by Ruan Mager, as far as Corner Pradanack, including the promontory called the Lizard Point: in this space, there are two formations of rocks, in subordinate beds, and of different natures, the one mica slate, to the S.S.W. of the village of Lizard; and the other the soap-rock, to the north of Kinance Cove. The colour of the latter is whitish, or straw-yellow, streaked with red, green, and purple: it is soft and wet when first taken out, but soon becomes hardened: it is found of three degrees of purity; the first, called the *best-best*, is uncommonly white. This kind is used in the manufacture of porcelain, as it contains, naturally, the same proportions of magnesian and argillaceous earth, which are artificially mixed, for the purpose of manufacturing the finest Worcester China. The whole soap-rock is rented by the proprietors of the porcelain manufactory in that city.

The mineralogist will find many rare and curious specimens in this county: some of them have been already incidentally mentioned. The following also deserve notice: Green carbonate of lead and apatite, near Heslton; blende, in twenty sided crystals, and green fluor, in twenty-four sided crystals, at St Agnes; crystallized antimony, with red blende on quartz, at Huel Bays; yellow copper ore and opal, near Roskier; and arseniate of copper, in cubes of a bright grass-green colour, from Huel Carpenter. Formerly *wood* tin, as it is called, was found at Poth in great abundance, but it is now scarce: in colour it resembles *hæmatites*, and is finely streaked like radiated zeolite. It is so hard as to emit sparks with steel, and, when broken, has a fibrous appearance. According to Klaproth, it yields more than sixty-three parts of tin in a hundred. The *elvan* stone of the Cornish miners is also found at Polgoth: it is a greenish, or cineraceous granite, with some *steatites* intimately blended with the quartz, mica, and felspar. Under some of the granite rocks, which project from the shore near Pengerswick, there is an extremely hard, black, schistose substance, apparently a species of hornslate: a similar species, with their veins, of a whitish colour, between the laminæ, may be seen near St Roche. The Cornish moor-stone, a very close species of granite, that takes a good polish, and is applied to a great variety of purposes, is found abundant near the Land's End: it is split, by applying several wedges to holes made on the surface of the stone, about three or four inches from each other; and it is remarked, that the harder the mass, the more easily and regularly it is cut: it is sometimes used for posts, instead of wood, in pieces of from 14 to 15 feet in length, and not more than six inches thick. In the Gwennap mines, to the south-east of Redruth, the substance called *gossan* abounds: it is of a reddish or yellowish brown colour, amorphous, and principally composed of oxide of iron, mixed with argillaceous particles: it is regarded by the miners as indicative of the neighbourhood of a rich vein. In Caharrack mine, red, vitreous copper ore, with octahedral crystals, and some varieties of arseniate of copper, are found. It is also said, that asphaltum has been found in this mine, at the depth of 90 yards. At Huel Unity, black fuliginous copper ore, a very rare mineral in other countries, is found; and at Huel Jewel, the substance called *growan* by the miners. It is now, however, become extremely scarce: it is a granite, consisting of transparent glassy quartz, a small portion of felspar, and mica in a decaying state. The crystals of tin which this substance contains are in tetrahedral pyramids, and of a colour like rosin; wolfram is also distributed through the mass. In one of the mines near St Agnes, the sulphurated ore, discovered by Raspe, was dug. He proposed to call it bell-metal ore: according to Klaproth, it contains, out of 119 grains, 30 of pure sulphur, 41 of tin, 43 of copper, 2 of iron, and 3 of the stony matrix. Its colour is like that of the grey copper ore, its texture lamellar, and it is extremely brittle. In one of the tin lodes of Polgoth mine, the *schiefer spar* of Werner was discovered some years ago. On this circumstance, Dr Maton remarks, "calcareous substances are very scarce in Cornwall; and I was not a little surprised to hear, that the schiefer spar (which is one of the scarcest species, and had never been before found, but at Konigsberg, in Norway, and in Saxony) was a na-

Cornwall. tive of this county. I am informed, that the Rev. Mr Herneth of St Austle is in possession of a crystallized variety, with erect hexagonal plates." The miners remarked, that from the period of the discovery of this substance, the lode ceased to be productive. The Denyhall slate quarries, near Camelford, produce a species of slate of a peculiar texture; if it is struck, the sound it emits is almost as clear as that of metal: its colour is greyish blue: it splits into *laminæ*, sometimes sufficiently large for grave-stones: it is equal to any slate in the kingdom for roofs. The *Cornish diamonds* must not be passed unnoticed. They consist of beautifully transparent quartz, in six-sided pyramids, with a hexagonal prism. Their specific gravity is from 2.64 to 2.67. They are composed of the purest siliceous earth: some of them are colourless; others stained with metallic oxides. The most remarkable and rare kind have hexagonal sheaths, described one within the other,—a structure which has puzzled geologists. In a copper mine near Redruth, a curious substance, called the swimming-stone, is found. It consists of right-lined laminæ, as thin as paper, which intersect one another in all directions, leaving, however, unequal cavities between them. In consequence of this cellular structure, the stone is so light that it swims in water.

Rare plants. Of rare plants, the following may be noticed as growing in Cornwall: near Fowey, on a slaty soil, to which it is extremely partial, *Sibthorpia Europæa*, which was discovered by Ray between 1670 and 1677. Near the village of Mullion, *Erica vagans*, the most rare and beautiful of the English heaths, grows in great abundance and luxuriance: it is also found near Helston. About the Lizard, *Asparagus officinalis*, and *Herniaria glabra* are found, but in no great abundance. *Tamarix gallica*, a shrub, for a long time not arranged among the British plants, grows wild in this part of Cornwall; some suppose that it is not indigenous to England, but was brought by the monks from Normandy to St Michael's Mount, and that it has spread thence over the west of Cornwall: it thrives rapidly in situations most exposed to the sea, and forms there an admirable shelter. On the borders of Mounts Bay, *Santolina maritima, Eryngium campestre, Panicum dactylon, Euphorbia Peplis, Euphorbia Paralias* are found. On the skirts of a wood, about a mile north from Bodmin, one of the rarest British plants has its *habitat*, viz. *Ligusticum Cornubiense*. *Laver* or *lichen marinus* is com-

Shells. mon on the shores of Cornwall; they also afford several uncommon species of shells; near Falmouth Dr Maton discovered *Tellina proficua*, and *Cardium exiguum*; and also a non descript species of *Venus*, which he named *Venus Cardioides*, from its resemblance to the *Cardia*. Treryn Cove, which is almost close to Castle Treryn, affords also several of the rarer species of shells: *Patella pellucida* is very abundant; and *Patella fissura, Mytilus modiolus, Trochus Cornutus*, and *Turbo Cimex*, are not uncommon on the rocks about the shore; near St Ives, *Helix maculosa*, one of the most elegant and rarest species of British shells, is found. In form and colour it approaches so nearly to the common snail of our downs, that it is very likely to be confounded with it, but the size will be found to be considerably larger.

Uncommon crow. The native cattle and sheep of Cornwall have been already noticed and described. There is also a species of crow, which, though not peculiar and confined to Cornwall, is so common on its coasts, that it is called the Cornish *chough* or daw: it frequents ruined towers by the sea side, and sequestered craggy rocks, especially on the part of the coast near St Michael. It is easily distinguished from the common crow by the redness of its legs and bill; and by its colour, which is a sort of violet black; it is remarkable for its propensity to steal and carry away whatever it finds, and it has been accidentally the cause of setting fire to houses by conveying lighted brands to the roofs; yet the natives are so much attached to it, that it is not uncommon to see tame ones in their gardens.

Fish. A great variety of fish are found on the coasts of this county, but none are so considerable an object of commerce, or afford employment and subsistence to so many people, as the pilchard. The pilchard fishery is carried on at St Ives, on the northern coast; in Mountsbay, on the southern; and thence eastward at St Mawes, Megavessey, and quite to the Devonshire coast. The pilchards make their appearance about the middle of July, and depart for the arctic regions about the end of September. The fishermen say, that fifty years ago, they did not leave the coasts of Cornwall till Christmas. The dog-fish haunts the coasts, and devouring the pilchard eagerly, is a great enemy to the fishery. Two kinds of nets are employed, a *stop seine*, which is generally 22 fathoms long, 16 fathoms deep in the middle, and 14 at each end: some of these seines will contain upwards of 200 hogsheads, each hogshead holding nearly 3000 fishes: the other kind of seine, is called a *tuck* seine, which is made similar to the *stop seine* but smaller, being generally only 108 fathoms long and 10 deep: three boats are necessary for each seine: the number of men employed varies from 17 to 24: they are paid partly in money, and partly by a share of the fish and oil. Sometimes a seine will take from 1000 to 1500 hogsheads in a season: the whole quantity may be averaged at about 50,000 hogsheads, of 40 gallons each, and 3000 fish in each cask. Some of the fishermen are stationed on the rocks to watch the course of the fish; these are called *huers*, from setting up a hue, when they observe a drove of pilchards. As soon as the fish come within the depth of the seine, the boat containing it is rowed round them, and at the same time, the net is thrown over; by this means they are completely surrounded; the fish are suffered to lie in the stop seine till low water, when they are taken out with the tuck-seine, and carried to the store-houses: if the quantity be very large, it sometimes requires several weeks to take them all out, as they must be salted immediately on their removal. The floor of the store-houses on which they are laid, is on a gentle declivity, that they may be kept dry and in good condition: in the store-houses, as well as in every cask, a quantity of salt is spread between every layer of fish; and in the packing, they are pressed very hard, with great weights, by the power of a strong lever. The oil is thus extracted: the pressing continues about 14 days, when the fish are fit for the merchant. Forty-eight hogsheads of pilchards usually yield a ton of oil: 420 lbs. of salt is necessary to cure a hogshead; and the usual quantity provided for each seine, is 3000 bushels. Men, women, and children, but principally women, are employed in the various processes of washing, salting, pressing, and making nets, ropes, &c.; the number is at least 5000. The capital engaged in the trade is supposed to be £300,000. The principal market before the war was Italy. Attempts have been made, since it was shut up, or contracted, to open a market in the metropolis, but they have not succeeded.

Manufactures. There are very few manufactures in Cornwall. Carew mentions, that in his time, the women and children in the west part of the county, made mats of a small and fine kind of bents, "which for their warmth and well-wearing are carried by sea to London and other parts of the realm, and serve to cover floors and walls." The principal places of trade are Padstow, Boscastle, and the river Hayle, on the north coast; Penzance, Falmouth, Truro, Fowey, and Looe, on the south. The exports are tin, copper, moor-stone, china-stone, fish, barley, oats, potatoes, and some wheat. The imports are goods and groceries from London, Bristol, and Manchester: considerable quantities of coals are also imported. A great number of cattle and pigs, and some sheep, are driven annually out of the county.

Antiquities. Cornwall abounds with antiquities of very ancient date, and generally supposed to be Druidical; of these the most remarkable, as well as the most common, are cairns, circles, cromlechs, and logan stones. The cairns are similar to those found in Scotland, and consist of a large heap of stones, piled up, generally on some mountain or eminence: *cromlech*, in the Cornish language, signifies a crooked stone. Near Castle Chun is a large one called the giants coit, which consists of four stones, the upper one, which is very large and heavy, resting on the other three, which are not placed erect, but inclined considerably. Dr Borlase is at a loss for the meaning of the word *logan*, but the word *log*, from which it is evidently derived, is very usually applied, both in Devonshire and Cornwall, to any thing moving to and fro. The most singular logan stone is near Castle Treryn: it is an immense mass of granite, probably more than 90 tons weight, poised in such a delicate and exact manner, on the top of one of the highest rocks, that a child might move it. The logan stones are generally supposed to be the works of art, or rather of human strength; but it is impossible to conceive how this one could be placed, where it is, by any human exertion. This consideration, and an attentive view of its structure, has induced Dr Berger to offer a much more plausible conjecture: in his Essay on the physical structure of Devonshire and Cornwall, he says, "I am satisfied that the logan stones formed at one time only one complete mass of granite, which, by the action of the atmosphere and other external agents, has split into irregular blocks; the greater part of these, though separated on all sides from each other, have remained in their original position, but now appear, as if they had been placed one above another." (*Transactions of the Geological Society*, p. 149.)

Views. There are some grand and impressive sea views in this county, particularly the view of St Michael's Mount, and of the Land's-end. The latter can scarcely be regarded without admiration, awe, and terror. There is a fine view of a very different character, afforded by the scenery round Loo-pool, about two miles from Helston: there is a picturesque richness and variety in this scenery not often afforded in Cornwall.

Pastimes. The people of Cornwall are celebrated for their fondness for athletic sports, in which they are very expert: the principal of these are wrestling and hunting. They are usually practised on holidays, particularly on the Monday and Tuesday after the Sunday which is kept annually in memory of the dedication of the parochial church. The tinners have holidays peculiar to themselves, particularly the Thursday before Christmas day, in commemoration of block tin being first melted into white; for formerly the tin ore was exported unmelted. The inhabitants of this county are in general of a large and strong make: this, joined to their skill in wrestling, has given rise to the proverbial expression, a *Cornish hug*. The miners are not long lived; few of them reaching beyond 55.

Parliamentary boroughs, &c. There are more parliamentary boroughs in this than in any other county in the kingdom; it returns to the House of Commons 44 members. This seems to have risen, in a great degree, from the large hereditary revenue yielded by the duchy to the crown, and is not of very ancient date. Cornwall is in the diocese of Exeter, and in the western circuit: it sends 640 men to the militia, and pays eight parts to the land tax. The assizes are held alternately at Bodmin and Launceston. Till about three centuries ago, a peculiar language was spoken in Cornwall, which was evidently Celtic, and allied to the Welsh and language of Bretagne. When Mr Barrington visited Cornwall in 1768, he found only one woman who could scold in it.

Ancient inhabitants. On the invasion of the Romans, this county was inhabited by the *Danmonii*, who a short time before that event had subdued the *Carnabii*, in the Cornish language Gwyr Cernyn, or the men of the promontory. The Romans included it in *Brittannia Prima*. When they withdrew from this island, Vortigern, earl of Cornwall, was chosen by the British chiefs as their head; but he, instead of trusting to their bravery, called in the Saxons. In consequence of the cruelties and oppressions of these new settlers, many people emigrated from Cornwall to the opposite coast of France, which thence took the name of Bretagne. Cornwall was not finally subdued by the Saxon kings of England till the year 938, in the reign of Athelstan; and some historians are even of opinion that he did not take possession of it, but merely obliged the inhabitants to confine themselves within the river Tamar. However this may be, William the Conqueror made Robert de Merton earl of Cornwall, with 793 warriors. His son taking part with Robert, duke of Normandy, was deprived of the earldom by Henry, who gave it to Reginald de Dunstanville. Henry II. took it on his death, into his own hands, and gave it to his youngest son John, who held it till he was king, at which time he granted it, first to Henry Fitzcount, and afterwards to his own son Richard, who was distinguished for his power and riches, and for his expeditions to the Holy Land. He was succeeded by his son Edward, on whose death, without issue, King Edward I. seized it, and gave it to his son, who, on mounting the throne, bestowed the title and honours on his favourite Gaveston. On the execution of Gaveston, Edward III. conferred it on his brother John de Eltham; and, on his death, the title was raised to a dukedom, and Edward, surnamed the Black Prince, was invested with it. Ever since that time the oldest son of the king is duke of Cornwall, sometimes by birth, and sometimes by patent. Of the immense hereditary revenues formerly belonging to Cornwall, only the income derived from the Duchy lands, and from the duty on the coinage of tin are unalienated.

The following statistical abstract is taken from the population return for 1811:—

Inhabited houses	37,971
Families occupying them	44,189
Houses building	441
——— uninhabited	1,400
Families employed in agriculture	17,465
——— in trade, manufactures, &c.	10,954
——— not included in these classes	15,770
Males	103,310

Corona, Coroner,

Females 113,357
Total 216,667
Population in 1801 188,117

Increase since 1801 28,550

CORONA. See OPTICS.

CORONER (*coronator,* from *corona,* the crown) is the name given to a very ancient officer of the realm at the common law of England, of whom mention is made so early as king Athelstan's charter to Beverley, in the year 925. He is called coroner, because he has principally to do with pleas of the crown, or such as more immediately concern the king. According to this view, the Lord Chief Justice of the King's Bench is the sovereign coroner of the whole kingdom, and may, if he pleases, exercise the jurisdiction of that officer in any part of the realm. But there are also special coroners for every county in England, who are, along with the sheriffs, conservators of the peace in the counties where they are elected; and it is to these particular coroners that the following observations apply.

The coroner is chosen by all the freeholders assembled in the county court; for which purpose, there is a writ at common law *de coronatore eligendo,* in which the sheriff is expressly commanded, *"quod talem eligi faciat, qui melius et sciat, et velit, et possit, officio illi intendere."* By the statute of Westminster, i. c. 10, this officer ought to be a sufficient person, that is, the wisest and discreetest knight that best would and might attend upon such an office; there is also a writ in the register, *Nisi sit miles,* &c. from which it would appear that a coroner must be a knight, and have, at least, an hundred shillings rent of freehold; and there is an instance in the 5 Edward III. of a man being removed from this office because he was only a merchant. But at present it seems to be sufficient, if a man possess lands enough to be made a knight, whether he be really knighted or not; for the coroner ought to have estate sufficient to maintain the dignity of his office, and to answer any fines that may be imposed upon him for his misbehaviour; and if he has not enough to answer, the fine shall be levied on the county, as a punishment for electing an insufficient officer. The office of coroner, however, has now been suffered to fall into disrepute; and instead of being filled by gentlemen of property, who neither required nor would condescend to receive payment for serving their country, and who, indeed, were expressly forbidden by the above mentioned statute of Westm. i. to take any reward, under the pain of great forfeiture to the king, it has for many years past been conferred upon inferior persons, in indigent circumstances, who have offered themselves, with a view to the emoluments of the office, being allowed certain fees for their attendance, by the statute 3 Hen. VII. c. i. The coroner's office is for life; but he may be removed, in obtaining any other situation incompatible with its duties; or by the king's writ *de coronatore exonerando,* wherein the cause of incapacity must be assigned.

The duties of a coroner are either ministerial or judicial, but principally of the latter description; and they are, in a great measure, ascertained by the statute 4 Edw. I. *de officio coronatoris.* He is to enquire into the manner of death, when any person is slain, or dies suddenly, or in prison. This enquiry must be made *super visum corporis,* at the very place where the death happened, in presence of a jury of four, five, or six of the inhabitants of the neighbouring towns. If any person be found guilty of murder by this inquest, the coroner is to commit him to prison for further trial; and to enquire also concerning his lands, goods, and chattels, which are forfeited thereby, &c. This is called the *coroner's inquest,* or *inquisition,* which must be certified to the court of King's Bench, or to the next assizes. It is also the duty of the coroner to enquire concerning shipwrecks and treasure-trove.

Coronilla, Corporation.

The coroner, in his ministerial capacity, acts only as the sheriff's substitute, when any just exception can be taken to the sheriff. See Blackstone's *Comment.* b. i. ch. 9; and Jacob's *Law Dict.* (z)

CORONILLA, a genus of plants of the class Diadelphia, and order Decandria. See BOTANY, p. 282.

CORPORATION, is a body politic, or artificial person, of capacity to grant and receive, to sue and be sued, maintaining a perpetual succession, and enjoying a kind of legal immortality.

A corporation may be either *sole* or *aggregate.* It is *sole,* when the corporate rights are vested in a single individual; and *aggregate,* when they are vested in a number.

Corporations, of which there are various species, have been instituted for the advancement of religion, of learning, and of commerce, with the view of preserving for ever entire those rights and privileges, which, if vested only in the persons of individuals, would, like all other personal rights upon their death, be utterly lost and extinct. These political bodies would appear to have been originally invented by the Romans, and, according to Plutarch, were first introduced by Numa Pompilius, who instituted separate societies of every mechanical trade and profession. They were recognised, and much considered by the civil law, under the name of *universitates* or *collegia;* and adopted by the canon law, for the purpose of maintaining ecclesiastical discipline. The Romans, however, had no notion of *sole* corporations; with them the number of three was requisite; although a corporation, originally consisting of three persons, might still subsist when reduced to a single number.

Corporations, whether sole or aggregate, may be divided into *ecclesiastical* and *lay.* The former consist entirely of spiritual persons, and are erected with the view of promoting religion, and perpetuating the rights of the church. *Lay* corporations are either *civil* or *eleemosynary.* Civil corporations are erected for different temporal purposes, for the good of government, for the advancement and regulation of commerce and manufactures, &c. Eleemosynary corporations are constituted for the perpetual distribution of the free alms or bounty of their founder; such as hospitals, &c. By the civil law, it does not appear that any authority was required to create a corporation beyond the mere voluntary act and association of the members, provided it was not established for purposes contrary to the existing laws. But in England, the consent of the king is absolutely necessary to the establishment of a corporation, and this consent may be either express or implied. The royal consent is implied in those corporations which exist by force of the common law, to which former kings are presumed to have given their concurrence, and in all those which exist by prescription. The king's consent may be given expressly, either by act of parliament, or by charter. The creation may be made by the words "*creamus, erigimus, fundamus, incorporamus*," or the like. And the law even holds, that it is sufficient to create a corporation, if the king grants to a set of men to have *gildam mercatorium*, i. e. a mercantile meeting or assembly. The king, it is thought, may also grant to a subject the power of erecting corporations, upon the principle, *qui facit per alium, facit per se*. Such are the matriculated companies, erected by the chancellor of the university of Oxford, of tradesmen subservient to the students. Every corporation must have a peculiar name, by which alone it sues, and is sued, and performs all legal acts.

The powers, rights, and capacities, which are incident to all corporations, may be classed under the five following heads. 1. To have perpetual succession. 2. To sue and be sued, grant and receive, &c. by their corporate name. 3. To purchase lands, and hold them for the benefit of themselves and their successors. 4. To have a common seal. 5. To make bye-laws, or private statutes, for the better government of the corporation, which, however, must not contain any thing contrary to the law of the land, otherwise they are void. There are also certain privileges and disabilities incident to an aggregate corporation, which are not applicable to such as are sole. It must always appear by attorney. It cannot be made a party to an action of battery, or such like personal injuries. It cannot commit treason, or felony, or any other crime; nor is it liable to corporal penalties, nor to attainder, forfeiture, or corruption of blood. It cannot be executor or administrator, or perform any personal duties, or be seised of lands for the use of another. Neither can it be imprisoned, or outlawed, or excommunicated. An aggregate corporation may take goods and chattels for the benefit of themselves and their successors; but a sole corporation cannot. Aggregate corporations having, by their constitution, a head, cannot do any act during the vacancy of the head-ship, excepting that of appointing another; nor are they, while in that situation, capable of receiving a grant. But there may be an aggregate corporation constituted without a head. In aggregate corporations, the act of the majority is esteemed the act of the whole.

In order that corporations may not deviate from the end or object of their institution, the law provides proper persons to visit them. In the case of ecclesiastical corporations, the ordinary is constituted visitor by the canon law. In former times, the pope, and now the king as supreme ordinary, is the visitor of the archbishop or metropolitan; the archbishop of all his suffragan bishops; and the bishops of all the spiritual corporations in their respective dioceses. In regard to lay corporations, the founder, his heirs or assignees, are the visitors. In general, the king being held to be the sole founder of civil corporations, and the endower the perficient founder of all eleemosynary ones, the right of visiting the former is in the crown, and of the latter in the patron or endower. The crown's right of visitation is exercised in the court of King's Bench. If the founder of an ecclesiastical corporation appoints no visitor, the bishop of the diocese must visit.

A corporation may be dissolved; 1. By act of parliament. 2. By the natural death of all its members, in the case of an aggregate corporation. 3. By the surrender of its franchises into the hands of the king. 4. By the forfeiture of its charter. See Blackstone's *Comment.* b. i. ch. 18.

Corporations erected for the benefit of particular branches of trade and manufactures, to which the commercial policy of modern times has been extremely favourable, have been condemned, by the most eminent political economists, as injurious to the interests of the community. These injurious effects result, 1. From the obstruction of the free use and circulation of labour; 2. From the limitation of competition; and, 3. From the facility afforded to combinations among tradesmen, for the purpose of defrauding the public. The reader will find this subject amply discussed in Dr Smith's *Wealth of Nations*, passim. (z)

CORPUSCULAR PHILOSOPHY. See MECHANICS.

CORREA, a genus of plants of the class Octandria, and order Monogynia. See BOTANY.

CORREGGIO. Of the history of this very eminent painter, little is known with any degree of certainty. Even the exact time and place of his birth are points on which his biographers are not agreed, though it seems the opinion most generally received, that he was born in the year 1494, at Correggio, a small town in the duchy of Modena. With regard to his parentage and education, it is asserted by Vasari on the one hand, that he was the son of a labourer, who was unable to afford him the advantages of early instruction; while, on the other, Sandrart and Orlandi contend, that he was of a noble family, that he received a liberal education, and that he lived and died rich. It has, with great justice, been observed by Raphael Mengs, who was at infinite pains in collecting every thing that is known or conjectured of the history of Correggio, that the elegance and dignity of sentiment which appear in his works, strongly corroborate the supposition, that he possessed that general cultivation of mind which natural talents could scarcely have produced without the benefit of a good education. He is said to have received instructions in painting from Francesco Bianchi, surnamed Il Frari; and afterwards from Andrew Mantegna. But however that may be, he must be considered as little indebted to them for those peculiar excellencies which distinguish his works, in which grace, grandeur, and angelic beauty, appear in all the charms of the most delicate and harmonious colouring, and with all the magical illusions of the chiaro-oscuro, carried to the highest possible pitch of perfection.

The most important work of Correggio is the cupola of the cathedral at Parma, which he finished in 1530. This has always been considered as one of the most wonderful productions of the art. Its form is octangular, and the subject with which it is decorated is the Assumption of the Virgin, executed in fresco. In the upper part of the composition, he has represented the Virgin Mary, surrounded by an immense assemblage of angels, some throwing incense, and others triumphantly applauding. Every one must be struck with the angelic expression which he has given to them. The smoke of the tapers, which are constantly burning in the church, has considerably affected the colour of this work; but notwithstanding the dusky hue it has assumed, joined to all the disadvantages of a very unfavourable light, it continues to excite the surprise and admiration of every judicious beholder. Another great work of Correggio, and the first in point of time which he painted at Parma, is the cupola of the church of St John of the Benedictine Fathers. In the middle is the figure of Christ, suspended in air, with the twelve Apostles below, seated on clouds. These figures, which are naked, are generally allowed to combine, in a remarkable degree, greatness and beauty of form. They were much studied by the Carraccis, and considered by them as models for their imitation. It has been doubted whether Correggio ever visited Rome; but whoever considers the style of design in this composition, will be induced to believe that he had seen and studied the works of Michael Angelo. In the lunettes he has represented the four Evangelists, with the four Doctors of the Church. These figures, again, are remarkable for their resemblance to the style of Raphael. This resemblance is still more apparent in the St John, painted on the door of the vestry of the same church; from all which it is argued, that Correggio did not, as some have supposed, confine himself to the casual sources of improvement which existed in his native province, but that he had carefully availed himself of whatever he could derive from an attentive study of the works of his great predecessors. Following the account given by Vasari, it has been usual, with the subsequent biographers of the painters, to expatiate on the obscurity in which Correggio lived and died—the low prices paid for his labours—the timidity, diffidence, and melancholy of his disposition; and they close their sad account by informing us, that he lost his life in a fever, which was occasioned by bearing home on his shoulders sixty crowns in copper money, which he had received as payment for one of his works. What proportion of truth there may be in this statement, it is quite impossible to decide. The story of his death is generally believed to be true. But if we consider the cheerful gaiety of many of the characters he introduced into his compositions—the importance and extent of the works which he undertook and executed—and the remarkably excellent and costly materials which he often employed,—it is not certainly the conclusion to which we should be very naturally conducted, either that the habits of his mind had been characterised by melancholy and diffidence, or that obscurity and indigence were among the list of evils with which he had to struggle. But these facts, be they as they may, are of little importance to be accurately known. The various and contradictory theories which have been proposed, and the solicitude with which their respective authors have endeavoured to give them the appearance of probability, are perhaps worthy of any notice only in as far as they tend to shew the interest with which the subject of them has been regarded, and as exemplifying the natural and laudable propensity of the human mind, to attach importance even to the accidental and accompanying circumstances which have attended great talents in their progress to excellence and celebrity.

At the time that Correggio appeared, the art of painting had, by slow and progressive steps, arrived to great perfection. But, notwithstanding that dignity and grandeur of form which had been invented by the superhuman powers of Michael Angelo—although splendor and truth of colouring were conspicuously exemplified in the works of Titian, while expression and grace appeared in those of Raphael,—it still remained to combine, in an eminent degree, these different excellencies in one style. It seems admitted, by competent judges, that in the best works of Correggio, this happy union has been effected in a more remarkable degree than is to be found in those of any other painter. Even those, however, who are most zealous in his praise, do not pretend to deny that his drawing is, in general, inaccurate; although several of his works demonstrate that he fully understood this branch of his art, and that he could practise it when he chose. It does seem strange, that, with the power of sometimes being excellent in what is so justly considered of primary importance, he could allow himself to degenerate into habitual incorrectness of design. With regard to the style of Correggio, and particularly to this unaccountable paradox in his practice, we may quote the words of the late Mr Barry in one of his letters to Mr Burke. "I shall say nothing of Correggio's ceilings in the Duomo and in St Giovanni at Parma; they are, I will allow, what might be expected from the great abilities of such a man. But as I do not like this kind of painting where macchia and effect is more consulted than expression, beauty, form, and character, so I shall leave for others to say about it what they please. Correggio's fragment of the Annunciation is excellent, full of grace and beauty. His Madona della Scudella is admirably well coloured in all the parts, but the drawing is bad, and much wanting in the proportion, &c. This picture is a convincing testimony that he was ignorant of drawing (very ignorant), and yet some part of his other picture of S. Girolamo, at the Academy, proves as convincingly that he drew well, and very well, and in excellent, proper, and variegated proportions. To reconcile this might be more difficult and troublesome than useful, and therefore I will only suppose either that this Madona della Scudella was an early work of Correggio's, or that sometimes he made light of the drawing of his figures, or that sometimes he succeeded in his drawing more from pains and a habit of mere imitation, than from principles and knowledge. There are other pictures by him in S. Giovanni, in which there is much to praise and something to dispraise. In the Palace of S. Vitale is a little Madona and Child by him, which is very excellent, and much like Titian's manner of colouring, which is very different from the general style of Correggio."

With regard to this last remark, it must be observed, that the colouring of Titian is only to a *certain degree* compatible with the peculiar excellencies which characterise the style of Correggio. It was one of the great objects which this painter had in view, to give throughout the whole of his works a certain delicacy and softness in the outlines, so that in many instances his figures seem as it were blended with the grounds on which they are painted. To this is owing one of the most characteristic circumstances in his style; for almost to this alone is to be ascribed that extreme delicacy and tenderness of effect, which we look for in vain in the works of the Roman or Venetian schools. Now, it is a fact well known to the professors of the art, that in proportion as the contour is made soft and blending, in the same proportion it becomes necessary to discharge all decided and positive colour from the picture; and, on the other hand, whenever such decided and positive colours are introduced, it is absolutely necessary to support these by a corresponding strength and hardness of outline. There is therefore a natural limit to the compatibility of the peculiar qualities which, in this respect, Correggio had it in his view to combine, and of that limit he seems to have been thoroughly aware. The law of art by which he was guided in this respect is plainly founded in nature. The degree of light, which shews strongly and sharply the outlines of objects, (in every instance, excepting in the case of their being seen opposed to a light,) must at the same time serve to show their local colours in a corresponding degree of distinctness; and, on the other hand, if we diminish the light which falls on objects, till at last we lose sight of all sharpness of outline, we must, in the same degree, lose sight of all distinct local colour; so that if we set out with the principle of introducing bright colours, we must of necessity give up that tenderness of outline which Correggio esteemed so great a beauty; or if we adopt his tender outline, variety of colour, in a great measure, must be avoided, as inconsistent and unnatural. In this country, there are few genuine works of Correggio to which we can refer as examples, to illustrate how far this general rule guided his practice. We may, however, mention the beautiful specimen in the possession of Mr Angerstein, which represents our Saviour praying in the garden, and an angel listening, while the disciples are seen at some distance sunk in sleep. The utmost degree of tenderness and delicacy as to outline, and the greatest sobriety and softness of effect, are remarkable throughout the whole of this highly beautiful composition. A solemn twilight is spread over all the parts of it; and as there is scarcely a single sharply marked line, so there is scarcely any distinguishable variety of colour, and the whole is reduced nearly to the simplicity of mere chiaro-scuro. There is also a picture by Correggio, but somewhat different in the general management and effect, in the possession of Mr Otley of London, in which the artist has represented the story of Jupiter and Io. A greater degree of illumination is admitted into this composition; and, in conformity to the law we have stated above, the contours are more firm and decided, and a greater strength and variety of tint is introduced. Chiaro-scuro is so inseparable from design, that the one cannot perfectly exist without the other; because design without light and shadow can only represent a section of an object, and can therefore never express the form of its surface. Correggio is eminent for the knowledge and skill with which he models, as it were, the surfaces of the objects he represents, so that one may see in his pictures where the surface rises, or where it sinks, even though his outline were hid, and that with the same appearance of reality, as if we were looking at the natural objects themselves. For his excellence in this respect, he is said to have been indebted to his study of sculpture and modelling under Antonio Begarelli, of whom Michael Angelo speaks in high terms of praise.

Of his oil paintings, one of the most celebrated is the picture called the St Jerome of Correggio. In this picture he has represented the Virgin Mary seated, with the infant Jesus on her knee; Mary Magdalene, in a kneeling attitude, embraces the foot of the Saviour, whilst St Jerome presents a scroll to an angel. The two altar pieces, which he executed for the church of St Giovanni, are also much esteemed; one representing the martyrdom of St Placido, and the other the descent from the cross. These inestimable pictures have been torn from their situations by the French, and are now deposited in the Museum of the Louvre. It is worthy of notice, that the French artists then resident at Rome, in a memorial highly creditable to themselves, stated to the National Convention the injury which the cultivation of art would receive from removing those *chefs-d'œuvre* and others from the situation for which they were originally painted. But this amiable appeal met with the reception which might have been expected from such a tribunal.

In the gallery at Dresden is his famous work, called the Notte, representing the Nativity, and an exquisite picture of the Magdalen reading. There are two pictures that have also been much celebrated, which originally were presented by the Duke of Mantua to Charles V. and which afterwards were in the collection of the Duke of Orleans. One represents Leda and the other Danae. In both compositions the fables to which they allude are told with all the delicacy that is consistent with their being intelligible. A story which is given by Azara of these two pictures is worth mentioning, as a curious instance of that capricious fate which sometimes attends the noblest works of art. They had been sent by the Emperor Charles V. to Prague, where they were placed in the royal palace, and where they remained till the famous thirty years war, when that city being sacked by the Swedes, Gustavus Adolphus sent them to Stockholm. That king being dead, they remained unknown in the minority of Queen Christina, until an ambassador, who knew the history, sought after these paintings, and at last found them out serving as shutters for the windows of a stable. "They were repaired," he adds, "and that queen esteemed them as they merited; she carried them herself to Rome as precious things, and obtained previous license of the Pope to take them out of the Popedom whenever she wished."

We must not omit mentioning the celebrated anecdote of Correggio, which is told by those of his biographers, who admit the fact of his having ever visited Rome. It is said that, on beholding the frescoes of Raphael in the Vatican, he gazed in silence for a long time on these divine works, and that at last, conscious of his own transcendent but less regarded talents, he broke forth in the expressions of a manly and just self-confidence, "*Ed io anche son pittore.*"

On the whole, when we consider the perfection to which this illustrious person carried his art, the sweetness and delicacy of his execution, the unrivalled harmony of general effect which appears in all his works, the truth and illusion of his light and shade, and the perfect knowledge he displays in all the mechanical parts of his art; but above all, when we consider the dignity of his conceptions, and that character of celestial purity and beauty which he has imparted to many of the more exalted personages in his compositions; while, on the one hand, such a combination of excellencies must place Correggio in the highest rank as a painter, the very nature of those excellencies, when thus carried to such a degree of perfection, seems, on the other, absolutely irreconcileable with the commonly received opinion, that through all the disabilities of ignorance, indigence, and obscurity, he sought out his way to these without a guide, and that he never even saw the works of his great contemporaries and predecessors. That such an opinion, without the very best evidence to support it, should ever have gained currency, seems strange; an opinion inconsistent with all that we know of the natural progress of the art itself, at variance with the fixed laws which regulate and limit the progress and power of the human faculties, and contradicted by the direct testimony which even the works of his early years contain. When we consider, also, the moderate distance between his native province and the great depositories of the arts in Rome and Florence, it seems inconceivable that he should not have visited these, unless we can suppose that, among the other marvellous circumstances in the structure of his mind, it was deprived of the principle of ordinary curiosity.

He died in 1534, in the prime of life. The family name of Correggio was Alegri. He sometimes signed himself Antonio Lieto da Coreggio. (*t*)

CORRIGIOLA, a genus of plants of the class Pentandria, and order Trigynia. See BOTANY, p. 168.

CORSICA.

Corsica. Boundaries.

Corsica, (*the Island of,*) is situated in the Mediterranean Sea, between the 41st and 43d degrees of N. latitude, and the 8th and 10th degrees of E. longitude. It is bounded on the north by the Ligurian Sea and the Gulf of Genoa; on the east by the Etruscan Sea; on the south by a strait of about 10 miles in breadth, which separates it from Sardinia; and on the west by the Mediterranean. It is about 40 leagues distant from the coast of Antibes. It is nearly at the same distance from the coast of Genoa. It is 20 leagues distant from Tuscany, and about four from Sardinia. Its greatest length from the most northern part, which is Cape Corso, to the southernmost near Bonifacio, is about from 38 to 39 French leagues. Its breadth, which is unequal, is in some places 18 leagues, in others it is 15, and in some it is yet much less. Its coasts are indented by several gulfs and creeks, which renders it difficult to ascertain its precise extent. It cannot, however, be less than 120 leagues round, and its superficial measurement may be estimated at 527 square leagues. A chain of mountains traverses the island in form nearly of a cross, beginning at Bastia, and thence to its most southern point dividing it into two parts, the east and west, which are distinguished by the inhabitants as the parts on this side and on that side of the mountain. Fertile vallies extend on all sides around the mountains in the interior, reaching even to the sea-coast, and agreeably diversified by rising grounds, which, as well as the mountains themselves, or at least the lower of them, are also considerably productive. The loftier of the mountains are for the most part of the year covered with snow.*

Climate.

The climate of Corsica is mild, the cold which proceeds from the mountains being tempered by the sea-breezes, and on the other hand, the wind which blows over them rendering the summer's heat less oppressive. Violent storms are not uncommon in the winter months. The air, however, is for the most part clear and salubrious, except in places in the vicinity of stagnating waters and marshes, which are here numerous, and the inhabitants live to a very great age.

Agriculture.

Corsica produces wheat, rye, barley, millet, but no oats. The horses and mules are fed with barley. The returns obtained here by the cultivator are very great, extending to 60, 80, or even to 100 or more, for one. This abundant increase is by no means the consequence of superior skill or industry on the part of the occupier. On the contrary, agriculture is here in a very imperfect state. The implements of husbandry are bad, and the Corsicans do not make the best use even of those which they have. Their labour does no more than scratch the surface of the earth; and the advantages to be derived from manures, which might be had in great plenty, are almost altogether unknown. There may be some exceptions to these remarks, and abundant harvests, it may be expected, will be found chiefly in those parts where there is the most of industry and of attention to the means of improvement. But the great source of those plentiful returns, is the prodigious natural fertility of the soil, which is manifested, as in other respects, so most happily and usefully by the great strength of the stalks that distinguish the grain of this country, and to which it is owing that the weight of the ears never causes any lodging of the crop. There are two circumstances connected with the state of this island, to which, perhaps, chiefly may be attributed the neglect of its agriculture. These are the figure of the island, and the political state of the country. From the vicinity of the most improvable parts of this island to the sea, and the consequent fear of pirates, it became less an object to bestow a careful cultivation, when the chances were so great that the same hands which sowed should not be permitted in quietness to reap the harvest. The imperfect state of internal regulations within the island itself, would naturally contribute to the effect thus produced by the fear of danger from without. It is impossible to estimate the new degrees of activity in cultivation, and of consequent benefit to those engaged in it, that might be the result of the settlement of this country in a state of greater security, and of adequate encouragements being held out to an improved agriculture. Even a farther extension of leases, which for most part have been limited here to one year, would lead to many meliorations, and to the substitution of a good method of culture, in the place of the abusive practices which ruined the land. These advantages have, in consequence of the improvements in those respects that have been already introduced, been experienced in some degree, and their farther extension would no doubt follow in a just proportion upon a more enlarged operation of the same causes.

Forests.

At the time that Corsica, in the year 1766, came into the possession of France, it was ascertained that 160 square leagues of its surface were occupied by forests. The most considerable of them is that of Vico. Among the resinous trees found in these forests, the pine and the larch are distinguished by their beautiful veining and the excellence of the timber. This is the case particularly as to the larch, which has the appearance of being a beautiful variety of the larch of the Alps, or of the cedar of Lebanon. Both those kinds of trees, in respect as well of the quality of the wood as of its dimensions, may serve for the parts above water of vessels of the largest size, and are indeed, for that purpose, superior to any thing that can be obtained from the north of Europe. It is to be observed, that the timber of Corsica generally is much harder than might be expected in so southern a latitude, owing perhaps to the rockiness of the soil of the country, to the perpetual currents of fresh air that are passing through the vallies, and to the cool temperature proceeding from the mountains.

Wines.

Several cantons of the island of Corsica produce excellent wines. At Cape Corso there are two sorts of white wine made, one of which has so much resemblance to Malaga, that a great quantity of it is every year exported to Germany, and is sold as the genuine wine of that name. Part of it is also sent to Leghorn for the English market, where in like manner it passes for the true

* The loftiest of the mountains of Corsica, is that called by the ancients Mons Aureus, and now Gradaccio, or Monte Rotondo. It is of a very great height, and commands a most extensive view of the whole of the island, together with Sardinia. There is also from it a distant prospect of Italy and France, and even of the Mediterranean, with many of its little isles. This mountain is of very difficult access, the upper part of it being almost a perpendicular rock.

Corsica.

Spanish wine. The other kind of white wine that is prepared at Cape Corso, most nearly resembles the French Muscat wine called Frontignac. At Furiani, there is prepared a white wine, which might pass for Syracuse, only that it is not quite so sweet, though it is perhaps superior to it. In some of the villages, there is a white wine made, of an agreeable sweetness, and which has the flavour of Tockay. At Vescovato and at Campoloro, a wine is produced, which has some resemblance to Burgundy. Throughout the whole island, indeed, there are found wines differing in their tastes, insomuch that it may seem surprising how within such narrow limits, as to the differences of soil and exposure, while often the level of the ground is the very same, there can be produced such considerable diversities. In general it may be observed, that the juice obtained from the grapes of Corsica is so generous, that though even unskilfully prepared, it always pleases, from the agreeableness of the natural flavour.

Raisins. Besides the wines, there is also obtained annually at Corsica an abundance of fruit for the preparation of raisins.

Trees, &c. The olive tree thrives in every part of Corsica. It appears, indeed, not to have been very early introduced into the island, as it is said that the Corsicans are indebted for its introduction to the father of the present emperor of France. It now constitutes a principal source of the riches of the country. The olive tree grows here to a greater height and thickness than it does in the southern departments of France. It succeeds better in cold than in warm years, and the oil obtained from it, though not prepared with due care, is yet considered to be of good quality. The lemon, the pomegranate, the orange, the almond, and the mulberry trees succeed also well in this island. Chesnut trees are very abundant and productive, and the fruit, which can be collected with very little trouble, serves as food both for horses and men. It is perhaps in one view a disadvantage, that a subsistence may here be so easily obtained, as the effect is to render the people indolent, and to throw an additional obstacle in the way of improved cultivation. Aloes flower here as well as in the east; and the Indian fig is also one of the productions. Several of the trees of this island attain to great dimensions, the oak and other inhabitants of the forest, not less than the fruit trees. Indeed a sufficiency of timber might be found here for the establishment and maintenance of a large fleet; and if it could be easily transported, a very great return of revenue might be obtained for the country from the sale of this description of its produce. A great deal of flax is raised in this island; but though considerable attention is paid to the culture of the mulberry trees, the quantity of silk that has been procured has never been of much importance.

Animals. The island of Corsica produces all kinds of wild and tame animals. Most commonly, however, they are of a smaller size than those of the continent. The same is the case even with the men of the island, whose stature does not usually exceed five feet. The horses of Corsica are of the Sardinian breed. Like the mules and asses, though small, they are active and strong. The horned cattle are in proportion of a larger size than the horses, but they are inferior in quality. Indeed there is a want of proper pasture in the island, so that generally the cows give but little milk, and the oxen are lean and cadaverous. Grazing generally is much neglected, and the produce of the dairy is in little request. Oil, as in Italy, and in almost all hot countries, supplies the place of butter, of which therefore but little is made. Some of the cantons, however, furnish cheese of good quality. There are here numerous flocks of sheep, which having excellent pasture on the mountains, the mutton is very delicate, and yields a very rich juice. This is in some measure a compensation for the badness of the beef of the country. The sheep of Corsica are in general black or tawny, a white sheep being as rare among the flocks of this island as a black one is amongst ours. The wool is coarse and rough in the pile, which is attributed by the inhabitants of the country to the sheep being of a mongrel breed. Attempts have been made to correct this defect by the introduction of better breeds from England and from Spain; but the graziers assert that the inferior quality of the wool is less the consequence of any thing in the breed than of the nature of the pasture. In proof of this it is mentioned, that sheep which yield but a coarse wool in one farm, will, if removed to another in which the pasture is better, give a superior fleece. It is not unusual in Corsica to see sheep with more than two horns: some have as many as six. The muffoli is a kind of wild ram, covered with hair instead of wool. It lives on the highest mountains, where it can hardly be approached; but when taken young, it is very easily tamed. There are here vast numbers of goats which browse upon the wild hills, and the forests abound in deer. The swine of Corsica, which are very numerous, having all a mixture of the wild boar, and being fed on chesnuts, form a very agreeable food. The wild boar is found on the island in great plenty. The Corsicans are very fond of the diversion of hunting this animal, for which purpose they have a race of dogs particularly well adapted to it. These have a smooth hair, and are something between a mastiff and a strong shepherd's dog, large and exceedingly fierce, but very faithful where they have once formed an attachment. Bees abound in this island. Indeed it has been noted for its swarms of those useful insects, and for its copious supply of their productions from the earliest times. Both the low grounds and the hills are plentifully stored with the plants which furnish those creatures with their most grateful food. The honey, however, of the island has generally been accounted somewhat bitter, owing to the access which the bees have to the boxwood and the yew. This bitterness is by many considered not disagreeable. The best of the Corsican honey is said to be that which is obtained from Caccia. The wax is noted for its goodness and firmness. There is abundance of hares in this country. Foxes are also numerous, and they are here extremely large and ravenous. But there are no wolves nor rabbits, and very few venomous animals.

Birds. Of birds, those which principally occur in Corsica are the eagle, the vulture, the wood-pigeon, turtle, thrush, blackbird, and many of the smaller species. There is likewise plenty of game, as partridges, woodcocks, snipes, and water fowl in the lakes.

Fish, &c. The sea coasts of this island, as well as the lakes and rivers, of which it has several, abound with fish. These are in the greatest variety, and of the best kinds. There are particularly noted a kind of thunny or sturgeon, the sardinas a fish of an exquisite flavour, and oysters. The oysters are found on different parts of the shore in beds, and are of a remarkable size. They are in such quantity, that, besides the consumption of the country, great numbers of them are exported to Italy. Beautiful coral is obtained upon the coast opposite to Sardinia: it is of all the three kinds, white, red, and black. There are several marshes towards the shore, some of which being filled with sea water, yield salt sufficient for the consumption of the island.

Lakes.

The principal lakes of Corsica are the Ino and the Crena, which are situated in the interior of the island, at the distance from each other of about two miles, but they have both their origin in the same mountain, viz. the Gradaccio. They are both of considerable extent.

Rivers.

The chief of the rivers is the Golo, which, taking its rise from the lake Ino, traverses several provinces, and runs a course of upwards of 70 miles before it falls into the sea. The Tavignano, rising from the lake Crena, has also a long course through a very rude tract of country. The Restonica is a small river, but is noted on account of the clearness and the agreeableness of its water, and for its quality of whitening every thing over which it passes. There are several other rivers of less consideration, and likewise many rivulets, which serve at once to enrich and to beautify the country. The fish which chiefly occur in those fresh waters are the trout and the eel: these are found in great plenty, very fat, and of an uncommon size. There are many mineral springs both of the hot and cold kind, in different parts of the island, which the inhabitants of the country consider to be very efficacious for the cure of various distempers.

Mineral productions.

Corsica is very rich in mineral productions. The mountains yield lead, copper, iron, silver, antimony, alum, granite, porphyry, and jasper. Fine serpentine stone, talc, asbestos, and saltpetre, also rock crystals, are likewise procured here. Some of the silver mines are very rich, and the iron is said to be of a superior quality, not yielding in hardness to the prepared iron of Spain, which is the best in the world.

M. Rampasse, who had been some time an officer in the Corsican light infantry, gives an account of a stratum of a particular iron ore which he found in this island. It occurred in a plain above the village of Calenzana, to the eastward of Galoria. It is placed horizontally in a yellow earth, which at times disappears throughout the whole length of the ore, and the mineral of which is presented in three different views. First, it appears under the character of scaly iron, arranged in thin layers, mixed with a yellowish ochrey earth; afterwards it assumes the aspect of a heavy blackish iron, compact, and almost entirely disengaged from every heterogeneous substance; and, lastly, it presents itself in elongated spheroids, from four to five inches in diameter, exfoliating at the surface, and compressed at the two sides, and at intervals consequently assuming an angular appearance. In consequence of the sandy character and composition of this ore, M. Rampasse denominated it *arenaceous iron;* and having procured specimens of it sufficient for making the necessary experiments, he ascertained that it was a very productive ore. The quality of this iron will probably be made known by the result of the assays of the council of mines, to which portions of the ore were, with a view to the farther trial of it, transmitted by the discoverer.

The same gentleman was at considerable pains in endeavouring to find specimens of the so much celebrated orbicular granite of this island. Having arrived at the village of Olmetto, on the gulf of Valinco, which had been pointed out to him as the place containing this granite, he examined minutely every corner in the vicinity. He sounded the small lake in the neighbourhood; he visited the sea-shore; he explored by every means the river Taravo, which flows in this quarter, and endeavoured to ascertain the composition of the granites lying upon the heights surrounding the great valley through which this river passes. Having then made a comparative examination of the various specimens of rocks which he had seen in the course of this investigation with the orbicular granite, he found that though in some of these specimens there were hornblend and feldspar, yet they were not disposed in the same order as in the orbicular granite, nor in the same arrangement. He conceives, however, that from the appearance which these present, there is some prospect that the primordial masses of this magnificent granite may yet be discovered. He is at least confident, that the small mass of it already known could have come from no other place: it was found isolated upon the beach of Taravo, half a league from the sea, in the gulf of Valinco; the angles of it were rounded.

Minerals.

M. Rampasse farther takes notice of a new rock, which he considers as an appendage of this beautiful granite of Corsica, and which he discovered in the Nicolo, one of the most considerable mountains of the island. Here he says he found a block of stone almost square, and about 4½ feet long. It was sunk into the ground, and exhibited on one of its sides globular bodies, remarkable from their disposition and colour, and which were fixed in the stony mass. Some of them were about an inch in diameter; others were larger or smaller, but all of them presented a peculiar character, which this writer had never seen in any stone. Not more than six inches of the rock appeared above ground, but the earth surrounding it having been removed, it was found to be two feet and some inches in thickness. Its angles also were observed to be entire and acute, from which it seemed probable that it had never been removed since it had been placed there. This was the more probable, as the part of the slope of the mountains where it was found was bare, and as among the various blocks and masses surrounding it, it was the only one covered with vegetable earth. This rock, the heart of which seemed to be porphyroidal, was ascertained, upon examination, to have its paste composed of stony elements of a petro-siliceous nature, irregularly disposed in small grains, in points and in lineaments more or less rounded off, and which tied as it were with each other, varying in colour in proportion to the various degrees of alteration which the ferruginous principle, that is very abundant in this rock, had undergone. The general aspect, however, when the rock was viewed from a certain distance, was the reddish brown, mixed with white spots, shaded with red. In the midst of this paste, there were observed regular spheroidal bodies, from one to three inches in diameter, scattered here and there at unequal distances, and imbedded in the mass. The system of the formation of these balls appeared to be, that they were the result of a globular crystallization, which had taken place rapidly, and not that like geodites they had been formed apart, and enveloped subsequently in a porphyritical substance. This method of crystallization is remarkable, and may be best conceived by representing a circle, into which a multitude of small stony bodies, oblong and compressed, of a petro-siliceous nature, and placed very close to each other, have been directed in radii, proceeding as it were from end to end, from the circumference towards the centre of the circle, and thus assuming the appearance of divergent radii. The globulous solid, which

Corsica.

has been the result of the process, may be driven with the hammer from the place which it occupies, a hole of the same form being left behind; and around these several spherical bodies in the paste of the stone, and round the spheres, the matter of the paste, according to the tendency it has had to approach them, has formed a kind of aureolus or zones.

Manufactures.

Manufactures are still in a very imperfect state in Corsica. Of the coarse and commonly black wool of the country, only the coarsest kind of stuffs can be prepared. Any thing of a finer description is obtained from abroad, the Corsicans having not yet advanced so far in art as to be able to furnish any thing of that character; and indeed the quantity of wool produced in the country not being adequate, without such supplies, to answer the internal consumption. Linen cloth is also prepared only in small quantities, and of the coarsest kind. There is plenty of leather to be had within the island, but that which is in most common use, and of which their shoes are made, consists merely of skins, particularly that of the wild boar, hardened in the air, without being tanned. Whether it be from poverty or indolence, the true process of tanning, though not unknown here, is but little practised. The little of their leather that is tanned, is so prepared by means of dried wild bay leaves, beaten into a powder, which communicate to it a greenish hue. The use of such materials for this purpose is not by any means the consequence of a scarcity of the more commonly approved materials. On the contrary, bark might be procured very easily, and in great abundance; indeed, it is in large quantities exported into Italy.

The Corsicans prepare themselves the oil which they use in their lamps; they likewise make wax candles, and a few tallow ones. Guns and pistols are manufactured in the country, most of which are of excellent workmanship, likewise great quantities of gun-powder. There are as yet, however, no founderies for cannon in the island, nor do the inhabitants make the bullets for which they have occasion in war. Notwithstanding the apparent facilities within their reach in this department, they are in like manner defective in the art of ship-building. They have, however, a number of small ships, and some of a tolerable size; and considerable prudence and spirit have sometimes been exhibited in the conduct of their naval affairs.

Trade.

The trade of Corsica is by no means considerable. It consists chiefly in the sale of the coral that is found on its coasts, and in an internal traffic of articles for home consumption. It has at various successive periods been placed under different regulations, and subjected to the controul of distinct superintendents. It might easily, however, receive a farther extension than it has ever yet obtained. For this, the situation of the island is not less favourable than its produce. The coast of Corsica every where almost affords good anchorage for vessels of a small draught of water, and there are numerous ports in all directions, into some of which the largest vessels may enter, and where they can be secure from every storm. The principal of these ports are, to the north, Centuri; to the west, San Fiorenzo, Isola Rossa, Calvi, Ajaccio; to the south, Bonifacio; and to the east, Bastia, Maccinajo, and Porto Vecchio. Centuri is indeed small, but might, without difficulty, be considerably enlarged. San Fiorenzo is a gulf which runs about 15 miles up into the country, of a good breadth, and with great depth of water. The gulf itself is often exposed to swellings of the sea from the violence of the west winds, but the various creeks and little bays that occur in it, especially in its southern part, afford good shelter for ships. The bay particularly, which is formed under the tower of Fornali, about two miles from San Fiorenzo, is very much esteemed, and is sufficient for the reception of the largest and most heavily loaded merchant vessels. They can lie there also in perfect safety. Isola Rossa is only a small haven, but it has the advantage of considerable depth of water, and is defended by a small island from the western winds. Calvi is a large and excellent port. Ajaccio is a spacious and commodious harbour, and has a good mole. Vessels may lie there in perfect security. Bonifacio is a very convenient harbour, and has from the most ancient times been much frequented by traders. Bastia is not such a port as might be adequate to the reception of ships of war, but it is very convenient for small vessels, to which its mole affords considerable advantage, both in respect of security, and for the better transaction of business. The islands of Gargona, also of Capraga and Elba, which are in this vicinity, are so happily situated as to prevent small vessels plying in this quarter from being ever without resources when overtaken by a storm. Maccinajo is but an inconsiderable harbour, but very safe and commodious for vessels of a light structure. The most noted of all the harbours of Corsica is Porto Vecchio, which is indeed one of the best ports in Europe. It is so spacious as to be capable of containing a large fleet, being about five miles in length, about a mile and a half broad, and of considerable depth. It has a good bottom, and is so defended by the neighbouring lands as to be secure from the violence of the storms. A majestic natural column, formed by a rock that rises hard by it, makes it easy to be discovered even from a great distance. The greatest inconvenience to which it is subject, arises from the badness of the air, which is occasioned by the marshes in its vicinity.

The abundant supplies which Corsica furnishes in all the departments of natural riches, joined to the facilities which its position and form thus afford for the prosecution of trade, certainly point it out as a place in which it were reasonable to look for a very extensive commerce. That the effect has not corresponded with the apparent causes, may have been owing to injudicious regulations in respect to the object, or to an indifference on the part of the people, the consequence of the state of thraldom in which they have too frequently been held, either by their native or by foreign rulers. In 1769, an exclusive right to the fishings about the island was, by letters patent, vested in two individuals. The Jews of Leghorn, in like manner, had obtained a monopoly of the coral trade. In 1798, it appears that almost the whole commerce of the island was in the hands of foreigners. It consisted chiefly in the export of some oil of an inferior quality —of wax, not equal in beauty to that of Mans—of tar—of raisins and wine—and, above all, of wood in logs and in planks. The little corn which was sent out of the country, returned to it again in meal, in starch, in dry pastes, and sea biscuit. The skins that had been sold in a raw state, were bought back again tanned, and dressed for boots and shoes. The coral fisheries were monopolized by the Neapolitans. The fishery of the thunny was engrossed by the people of Sardinia. The imports, as in all countries without industry and without arts, consisted in tools, utensils, furniture, drapery, iron-ware, and clothes.

Population.

The island of Corsica is not very populous. The intestine wars which have prevailed in it for ages, have

Corsica.

greatly contributed to its depopulation. In Pliny's time, there were in it no less than thirty-three large towns: their number is now reduced to nine. By an enumeration which took place in 1740, Corsica was found to contain 133 parishes, 427 villages, 26,854 hearths, and in all 120,380 inhabitants. Its population in 1760 had risen to 130,000. According to the state made out for the National Assembly of France, the number of its inhabitants was taken at about 147,000. M. Necker, however, in 1787, estimated them at no more than 124,000. By the last returns in 1802, they were found to amount to 166,813. Corsica is the twenty-third military division of France. For its civil administration, it is divided into two departments, the Golo, so called from the river of that name, and of which the chief place is Bastia; and the department of Leamone, of which the principal town is Ajaccio. The two departments are subdivided into 6 districts, 60 cantons, and 391 communes.

Various accounts of their character.

The Corsicans are well made, but thin and swarthy. They are the descendants of so many nations, and have at different times been placed in such variety of circumstances, that it is difficult to determine their real character. Strabo, who has described them as degraded by a state of servitude, calls them brutal, ferocious, and stupid. Diodorus Siculus, who gives an account of them whilst in the same condition, speaks of them as being naturally better adapted for bodily services than the slaves of other nations; and adds, that in their manner of living together, there was more of humanity and justice than was to be found among any other barbarous people; while in all their civil transactions they had a particular regard to equity. With this account of them Pliny's statement corresponds, who praises them as just, generous, valiant, and humane. This difference in the judgments formed respecting them, may have originated, in part, from their having been observed, in one case, under tyrants who maltreated them; in the other, as in the service of more equitable masters. For the rest, some of those who have most recently paid attention to this subject, have been disposed to give a preference to the authority of the historian over that of the geographer. In modern times, the Corsicans have been painted in the blackest colours by the Genoese, to whom they were subject, and who exercised over them a system of the most oppressive severity. They have received a more favourable, as well as a more impartial judgment, from Frederic the Great and Rousseau of Geneva. The former sets them up as an example of the courage and the truth with which the love of liberty can inspire men; and shews, by a reference to them, how dangerous and unjust it is to suppress so important a principle. The other, by his expression, "I love those characters in which there is stuff," seems to indicate his conviction of their possessing at least some strength and vigour of mind. By some late travellers, this people have been described as turbulent and ferocious; by others, as compassionate and hospitable, and restless only when oppressed. They have been accused of ignorance, indolence, want of probity and confidence, superstition, and above all, an extreme spirit of revenge. This last quality they are said to have been wont to carry to such an excess, that those who conceived their honour injured, would suffer their beards to grow till they had obtained satisfaction for the affront. These beards were styled *barbe di vindetta*. And, from the proverb, *Il Corso non pardona mai ne vivo ne morto*, as well as the sentence that passes current among them, *una inimicizia di sangue*, it seems as if enmities still continued here to be propagated from one generation to another. They have been described as having their habitations in the interior of the island, situated among rocks, on the most inaccessible parts of the mountains, and often removed at a great distance from any land proper for cultivation. They have been represented as at variance, and in a state of alienation even one from another; as careless of improvement, and indifferent as to the enjoyments, the refinements, and the elegancies of life. These traits of character have been traced in their supposed connection with one another, or with various circumstances in their history and actual condition. The oppressive government of the Genoese is said to have led to that vindictiveness of character with which they have been commonly charged. The state of seclusion which they have affected, and their spirit of enmity towards one another, were the consequence of the distribution of the country into several petty principalities, which respectively claimed and exercised for themselves the rights of war and peace. The wars in which they have been so constantly engaged, have had the effect of attaching them strongly to the sports or labours of the chace, and, in an equal degree, have formed them to a disinclination towards the occupations of agriculture, of commerce, and of the sedentary arts, and a mode of life in which hunting, keeping of flocks, and fishing, form the chief employment, has been generally found productive of that character of indolence, which has been stated to be found in an extreme degree among this people. After all, however, there are not wanting other authorities, which represent the Corsicans as sober, brave, intrepid, active, sagacious, and hospitable. Indeed, it will be understood, that, in respect to this people as to others, there may be many traits of their supposed character not universally descriptive, but rather of a local or temporary nature, and, consequently, liable to various modifications. Corsica, when subject to one undivided and regular government, may have been very different from the same Corsica when parcelled out among a multiplicity of inconsiderable chieftains. The thirst of vengeance, inspired probably, or fostered by the sense of a hopeless subjection to injurious treatment, has been found not incompatible with a kind and generous treatment of those who claim the rights of hospitality, and may, in various instances, have given way altogether, or, at least, have been greatly mitigated and restrained under the influence of well constituted tribunals, and of a watchful police. And an indifference to improvement, and listlessness of character, which may have grown amidst circumstances of adversity, may, in better times, have given place to a spirit more honourable and more useful.

Government.

The following is an outline view of the republican government of Corsica. The whole island is divided into nine provinces. Another division of it is into pieves, each of which again is subdivided into a certain number of parishes. This division is properly ecclesiastical; it is, however, also used for civil purposes. The Corsicans, even the peasantry, seldom live in detached situations; the manner is, to gather together in little villages, which are called Paeses. Each paese elects annually, by a majority of votes, a podesta, and two other magistrates, who have the respectable name of *Padri del commune*, Fathers of the community. To these officers, either alone or with certain assessors, nominated also by the people, it belongs to superin-

Corsica.

Government.

tend the economy and police of the village—to call the inhabitants together—and to consult with them on every thing that concerns their interest. Once a year, in like manner, the inhabitants of each village choose a procurator to represent them in the general consulta or parliament of the nation, which is held annually in the month of May, at the city of Corte. The magistrates of each province send thither, at the same time, a procurator, and there are several other honorary members. Before it proceeds to business, there are chosen a president and an orator of this assembly. The president governs during its sitting: the orator reads the different papers subjected to its deliberation. Propositions from the government are addressed to the president: those from the people to the orator. A proposition from the government, when approved by a majority of voices, is immediately passed into a law: one from the people, in the same circumstances, may be suspended by the government, but on the principle of its being subject afterwards to a proper responsibility. The procurators of the several provinces choose their representatives in the supreme council for the ensuing year, one of whom is elected into the office of great chancellor. These counsellors, with the general of the kingdom, are to form the executive power of the whole nation.

The general holds his office for life. He is perpetual president of the supreme council of nine. He votes in all questions, and in case of an equality has a casting vote. He is absolute commander of the troops or militia of the island.

The procurators of the provinces choose also the provincial magistrates for the current year. This magistracy is regularly composed of a president, two consultors, an auditor, and a chancellor; but the number is varied in different provinces, as is, indeed, also the magistracy in the different villages.

Both the magistrates of the villages, and the provincial magistrates, have a certain jurisdiction assigned to them in civil causes. The provincial magistrates have also, within determined limits, a jurisdiction in criminal matters. The chief judicial authority is vested in the supreme council. The ultimate rule of judging, is the civil and the canon laws, together with the particular laws of Corsica.

Besides the other elections, the procurators in the general consulta choose some persons of high credit and respect as syndicatori, whose office it is to make a tour through the different provinces, to hear complaints against the magistrates, to redress grievances, and, in short, to promote every where industry, order, and general improvement.

The hereditary feudal jurisdictions, which had place in Corsica as in other parts of Europe, having, by a fortunate concurrence of accident and wisdom, been so moderated as to coincide with the spirit, and even, in some degree, to promote the objects aimed at in this constitution of its government, have, in latter times, been attended with little inconvenience, indeed may, in some respects, have been productive of advantage.

Religion.

The religion of Corsica is the Roman Catholic, in which these islanders are very zealous. They are, however, decidedly inimical to the temporal power of the church. The Corsican bishops are five in number, and are suffragans of the archbishop of Pisa. The tithes in Corsica are, in general, about a twentieth part of every production. Several of the inhabitants have made a composition with the church for their tithes; and the descendants of the Caporale, on account of the services of that family in expelling the Saracens from the island, are, by special privilege, exempted from paying any tithes. There are, in Corsica, sixty-five convents of mendicant friars of different orders, which depend for their support altogether on the charity of the people. There are two colleges of Jesuits, two convents of Dominicans, five of Servites, and one of missionaries; all of which, as also the Carthusians of Pisa, have very good possessions. There are no nunneries in Corsica.

Learning.

The state of learning in this island, amidst the confusions and distresses to which it has, during the lapse of ages, been subject, has necessarily been at a low ebb. In 1764, a university was established in the city of Corte, of which the professors have mostly been fathers of different religious orders. About the same period, there were also in that city a printing-house and a bookseller's shop, but both conducted by a foreigner.

Language.

The language of the Corsicans is good Italian, tinctured a little with Genoese corruptions, and with some remains of the dialects of the barbarous nations. Their pronunciation is coarse, but they write the language in a great degree of perfection,

Arts.

A turn for the arts is prevalent amongst the Corsicans. Painting has not yet flourished among them, but they succeed well in music and poetry.

Army.

The warlike force of Corsica consists chiefly in a bold and resolute militia. The people are trained to arms from the time that they are able to bear them. Officers are appointed over the several districts, who call out the men, and otherwise give such directions as the occasion may require. The arms of the Corsican soldier are a gun, pistol, and stiletto, with a cartridge-box for his ammunition. The only instrument of warlike music that is used, is a large Triton shell pierced in the end, with which a sound is made loud enough to be heard at a great distance.

By whom first peopled.

Corsica was probably first peopled by the inhabitants of the opposite coast of Italy. It was successively conquered by the Carthaginians, Romans, Vandals, Goths, Lombards, and Saracens. The French, under Charles Martel, entered the island about the year 725; and the family of the Colonnas established themselves in the sovereignty of it about the eighth century. Owing to the family divisions, the troubles, and the consequent anarchy which for some centuries after this period prevailed in the island, an opportunity was afforded to the popes of interfering, and of claiming for themselves an authority which was now so ill exercised. Pope Gregory VII. excommunicated the Genoese, branding their occupation of Corsica as a usurpation of ecclesiastical property. In 1071, the island was sold by Urban II. to the Pisans. Genoa disputed the sale; and the island was afterwards divided into two rival republics. The Pisans not being able to come to any agreement respecting it with the Genoese, ceded again their part of the island to Pope Urban IV.; and Boniface VIII. as if the possession of a part gave him also a title to the disposal of the rest, made a present of the whole island to the kings of Arragon, from whom it returned under the yoke of Genoa.

History.

An assembly of the Corsicans as a national body, the first of which we have received any notice, was held in the year 1359, for the purpose of taking into consideration the evils to which they were subjected, both from the incursions of foreigners, who disputed with each other the possession of their country, and from the animosity of their nobility, who in certain districts had assumed the title and despotic authority of kings. A great part of the island was held at this time by the Genoese. To deliver themselves, therefore, from all other foreign authority, that of the Pisans and the Arragonese, as well as from the oppression of their own petty tyrants, the Corsicans, by the advice of the brave Sambuccio, requested the aid of this people, and associated them with themselves in the sovereignty of the whole island. This sort of mixed government was, however, only of a few years duration. The Corsican chiefs, weary of their state of subjection to a foreign yoke, assembled privately in 1380, and having chosen Henry de la Rocca to head them, they took, under his command, several of the Genoese garrisons. But Rocca, in the midst of these triumphs, having been killed in an action, the Corsicans were obliged again to submit to Genoa, in the fate of which republic they for a long time participated, being subject sometimes to the French, sometimes to the Milanese, and sometimes to the Neapolitans. In the end of the 15th century, they submitted to the lords of Piombino, by whom the island was sold to the bank of St George. This occasioned new stipulations with the Genoese; but these were soon disregarded, and the persons appointed to govern in the name of the bank had recourse to the most oppressive measures, subduing the opposition which they encountered by means of fire and sword. Eighteen parishes were destroyed, more than a hundred villages were burnt, and the chief men of the island were treacherously put to death. By such violent proceedings, the indignation of the people was roused. The French, who were at that time enemies to the Genoese, assisted the Corsicans to break their chains, and a most violent and unrelenting civil war was set on foot. Neither party gave to the other any quarter, and such as escaped the murderous sword, were sold as slaves to the Turkish corsairs who hovered about the island. In the progress of this contest, various dismal catastrophes occurred, and many examples were exhibited of a noble intrepidity, of the most persevering fortitude, and occasionally also of the milder though not less estimable virtues. It was the policy of the state of Genoa to govern entirely through fear. Corsica was considered merely as a colony destined to enrich its capital. All the exports of that state were directed to Genoese ports; and, in years of scarcity, the island being stripped of its provisions, the Corsicans themselves were frequently exposed to the horrors of famine, while their merciless and unfeeling tyrants lived in abundance.

The deliverance which they could not themselves effect, the Corsicans would willingly have obtained even at the expense of becoming subject to another master. They offered their island to Louis XIV. at the time that he was engaged in the bombardment of Genoa; but he having declined their offer, they were forced to remain in submission to their oppressors. Some incidental, and apparently trifling circumstances, however, excited anew a spirit of determined resistance on their own part, which seemed to promise a complete emancipation from the power of the Genoese. The latter people were obliged even to have recourse to the aid of Austria. But not with this accession of force could they terrify men who had resolved to be free. The Corsicans would listen to no proposals, but declared themselves willing to submit to every evil, rather than stop short of the object at which they had aimed. Necessity, however, got the better of their resolution, and, after the contest had been continued for 4 years, they entered into an agreement under the guarantee of the emperor. But the troubles were by this means but incompletely allayed, and soon revived. The Corsicans openly declared themselves independent, and set about making suitable preparations for supporting their pretensions. At this critical juncture, a seasonable aid was brought them by Stephen Theodore, son of Anthony, baron de Neuhoff. After various adventures in different countries of Europe, this nobleman had got acquainted with the Corsican malcontents confined at Genoa, and interested himself strongly in their behalf. Having, by persevering exertion, obtained an ample supply of such things as were most needful for a people circumstanced as the Corsicans then were, he set sail for their island, where he was received by them as a protecting deity. Without consulting the dictates of prudence, they conducted him to Corte amidst universal acclamations; and, in a general assembly of the people, he was proclaimed king of Corsica and of Capraja, under the name of Theodore I. Being well supported in the moment of enthusiasm, he took some fortresses of the enemy, and under pain of death, should they ever again set foot in the island, declared the Genoese banished from Corsica. The Genoese, on their part, by a policy too often resorted to by republics, set a price on the head of the new monarch. The baron, in the mean time, assumed all the appendages of royalty, coined money, established tribunals, and used every effort to maintain, and farther to extend, the ground he had gained. But while by these means he prevented or stifled discontent among his own subjects, he was exposed to danger from abroad. As he had at first landed on the island from an English vessel, the French imagining that the British government had some designs on Corsica, resolved to anticipate them. In the prosecution of the measures which he thought it incumbent on him to take on this occasion, the Corsican monarch was involved in difficulties, of which the conclusion was, that, having languished several years in prison for debts, he at last died in extreme indigence on the 11th of December 1755. Some time before the death of this prince, an accommodation had taken place between the Corsicans and the Genoese under the guarantee of France. A nobleman, however, named Gaffori, having communicated to his countrymen the hatred which he himself felt towards the oppressors, the war was renewed, and though the fate of the general was to be treacherously assassinated, it was not till the signal zeal which he had manifested for the welfare of his country had been crowned with some degree of success. Pascal Paoli was now recalled from Naples, whither he had gone for shelter, and when but 29 years of age was made head of the republic, in the government of which he was to be assisted by two counsellors of state, and one of the most reputable persons from each district, who were all to be changed monthly. Paoli, who had often before been opposed to the Genoese, conducted himself so well both in the council and the army, as to give great uneasiness to that people, who, in consequence, sent a deputation to a general assembly convoked at Vescovato, to offer peace. The Corsicans, however, would be satisfied with nothing less than a distinct acknowledgment of them as a free and independent nation. In support of this determination, the general enrolled all the inhabitants capable of bearing arms, disciplined his troops, caused money to be coined, and made his administration at once feared and respected. The Genoese were driven from the open country, and shut up in the maritime towns. They again, however, obtained assistance from France. In 1764, the French general Marboeuf, an

Corsica. History.

officer of considerable talents, landed with six battalions. The caution and political prudence which Paoli now thought it his duty to employ, nor yet the more active exertions in which afterwards he had occasion to engage, proved eventually sufficient for the safety or for the maintenance of the independence of his country. It was expected that England would take part in the quarrel; but this hope having been disappointed, and the sovereignty of the island having been renounced by Genoa in favour of the king of France, Corsica was, in 1768, invaded by a French army of 5000 men, under the command of the Marquis de Chauvelin, supported by two ships of the line, two frigates, and six armed brigantines. In the furious contest which ensued, numbers, military science, and discipline, were opposed to an almost unarmed multitude, to enthusiasm, bravery, and the cause of liberty. It was not, however, without considerable difficulty, and till after the aid had been obtained of some farther reinforcements, that the subjugation of Corsica was effected by Count de Vaux in 1769. Paoli having defended his country to the last, escaped in an English ship to Leghorn, whence he afterwards repaired to London. Both he and the Corsicans who acted along with him, are highly complimented by the celebrated General Dumourier, (who served in the French army as adjutant general,) in the memoirs which he has published of his own life.

Paoli having taken the oath of fidelity to the constituent assembly of France, returned again to Corsica in 1792, when he was elected mayor of Bastia, commander in chief of the national guard, and president of the department. On the execution of Louis XVI. when there was every prospect that a civil war was about to take place in France, Paoli thought the opportunity favourable for rescuing his country from all subjection to a foreign yoke. Having determined, therefore, to call in the assistance of England, he invited Lord Hood, who was then at Toulon, and who had recently been foiled in an attempt against Corsica, to invade it anew. An expedition sailed from the bay of Hieres on the 24th of January 1795, for the express purpose of recovering it from the possession of the French. The towers of Morsella, Fornelli, and San Fiorenzo, were taken by the troops under the command of lieutenant general Dundas, and Bastia and Calvi having likewise yielded to the English, the union of Corsica with the British empire was unanimously voted in a general consulta that was assembled at Corte. This proposition was readily accepted on the part of the English commissioner Sir Gilbert Elliot, now Lord Minto, and he was in consequence immediately invested with the dignity of viceroy. Corsica did not however long continue an appendage of the British crown. Jealousies arose between the English viceroy and general Paoli. The latter returned to England, but, before his departure, exhorted his countrymen to continue steady in their allegiance to Great Britain. This exhortation was not much regarded by the Corsicans. The splendour of the victories of their countryman Bonaparte in Italy, determined them to return to their allegiance to France. The English troops accordingly evacuated the island, and Corsica has ever since continued a province of the French empire.

Cortes.

CORTES, Fernando, the conqueror of Mexico, was born at Medellin, a small town in Estremadura, in the year 1485, and descended from a family of noble blood, but of small fortune. He was originally intended for the law, and studied for a while at Salamanca, where he devoted himself chiefly to active sports and martial exercises. At this period of his life, his disposition was so turbulent, and his habits so dissipated, that his father was glad to comply with his inclination, and send him forth as an adventurer in arms. Being disappointed in his views of serving under the great captain in Italy, a fair opportunity soon offered of trying his fortune in the new world, by the appointment of his kinsman Ovando to the government of Hispaniola, in the year 1502. He was prevented, however, from accompanying the governor, in consequence of an unlucky accident which he met with, in attempting to scale a lady's window; he brought down an old wall upon himself, and was so much bruised as to be unfit for the voyage. He reached Hispaniola or St Domingo in 1504, and met with a cordial reception from his kinsman. He accompanied Velasquez in his expedition to Cuba, which was conquered in 1511. Velasquez, seized with that spirit of enterprise, which was so common and so inviting in that age of wonders, sent Grijalva on a voyage of discovery, who returned with the important intelligence of having discovered the rich and populous kingdom of Mexico, or New Spain. The next object was to accomplish the conquest of this newly discovered country. Velasquez fitted out an expedition for this purpose, chiefly at his own expence; but as he was of a jealous and suspicious temper, he could not easily find a commander whom he could trust with the conduct of such an important enterprise. Cortes was warmly recommended to him, and his choice was decided by his known activity and intrepidity, and also by the little personal consequence which he then possessed.

Scarcely had he been appointed to the command, when the suspicions of the governor were excited; and had he not hastened his departure with the utmost expedition, he would have been stript of the means of his future glory. Cortes sailed straight for Trinidad, and afterwards touched at the Havannah, to engage adventurers, and provide the necessary equipments for his small armament. To both these places Velasquez sent orders to deprive him of his commission, and commanded his lieutenant at the Havannah to send him a prisoner to St Jago. Cortes defeated all these measures, and after his plans were completely matured, he declared to his followers the jealous suspicions of Velasquez, and his determination to deprive them of the rich spoil which they had in prospect. They received the intelligence with the utmost indignation, and offered to shed the last drop of their blood in maintaining the authority of their commander. Cortes, on his part, swore that he would never desert soldiers who had given him such a signal proof of their attachment.

He now therefore prepared to sail, determined to assert his independence, and to renounce all his allegiance to Velasquez. His fleet consisted of eleven vessels; the largest of a hundred tons burden, which was dignified with the name of admiral: three of seventy or eighty tons; and the rest small open barks. On board this fleet were 617 men; of whom 508 belonged to the land service, and 109 were seamen or artificers. Only 13 of the soldiers were armed with muskets, 32 with cross-bows, and the rest with swords and spears. They had 16 horses, 10 small field pieces, and four falconets.

Such was the expedition fitted out by a few private adventurers to make war on a monarch, whose dominions exceeded in extent, all the kingdoms subject to the Spanish crown. They did not however engage in this enterprise with any fears, or with any doubts of their success: they were stimulated by avarice, and enthusiasm; the first, made them submit to any hardship and encounter every danger, whilst the second made them believe that they were fighting for the glory of God, and, on this account, sure of his protection. They erected the cross as their standard, with this inscription, *Let us follow the cross, for under this sign we shall conquer.* Thus, under the great emblem of peace on earth, they commenced an expedition of bloodshed and plunder.

Cortes touched at the island of Cozumel, where he had the good fortune to redeem Jerome de Aguilar, a Spaniard, who had been eight years a prisoner among the Indians, and who was afterwards extremely useful as an interpreter. Having left Cozumel he proceeded to Tabasco, where he found the natives unfriendly, and from thence he sailed to St Juan de Ulua. As he entered the harbour, a canoe full of people, among whom appeared to be some persons of distinction, approached his ship with signs of peace and friendship. They came on board without fear or distrust, and addressed him in a language totally unknown to Aguilar his interpreter. This circumstance caused great embarrassment, from which, however, he was fortunately relieved by a female slave, whom he had received from the Cazique of Tabasco. She perfectly understood the Mexican language, as she was a native of Mexico, but had fallen into the hands of the Tabascans, among whom she had resided long enough to learn their language, without losing her own. She was afterwards called Donna Marina, and makes a conspicuous figure in the history of the new world. She explained the words of the Mexicans in the Yucatan tongue, which Aguilar translated into Spanish. The strangers proved to be deputies sent by Teutile and Pilpatoe, two officers entrusted with the government of that province, by Montezuma, emperor of Mexico: and the object of their mission was to enquire into the intention of Cortes in visiting their coast, and to offer him assistance in prosecuting his voyage. Cortes landed his troops, horse, and artillery; and the unsuspecting natives, with a fatal alacrity, assisted him in fortifying a camp, and erecting huts for his men.

Next day the two governors of the province entered the camp with a numerous retinue, and Cortes received them with much formal ceremony. He told them that he was the ambassador of Don Carlos of Austria, king of Castile, the greatest monarch in the East, and that he was entrusted with propositions of such importance, that he would impart them to none but the emperor himself. The officers were much disturbed at this intelligence, which they knew would not be agreeable to their master. They endeavoured, however, to conciliate the affections of the Spaniards by presents, consisting of fine cotton cloth, plumes of various colours, and ornaments of gold. These were fatal presents; they tended only to whet the avarice of Cortes and his companions, and he demanded in a more determined manner than ever, to be admitted to a personal audience with their sovereign. During this interview, several painters, in the train of the Mexican chiefs, were employed in delineating the ships, horses, artillery, soldiers, &c. on white cotton cloth, which Cortes was informed, was to be sent to the emperor, to give him a proper idea of what words could not represent. On learning this, he made his men go through their various evolutions, exhibited the power and agility of his horses, an animal till then unknown to the Mexicans, and last of all displayed the terrific thunder of his artillery. They beheld all the rest with astonishment, but when they heard the explosion of the guns, and saw the dreadful havoc which the balls made among the trees, they were filled with dread and horror: some ran away, others fell to the ground, and it was with some difficulty that Cortes could regain their confidence.

An account of all these things was sent to Montezuma, who immediately dispatched messengers to Cortes with rich presents, but with a peremptory order to leave his dominions. The Spanish commander on his part still insisted on a personal interview. Whilst negociations were carrying on between the Mexicans and Spaniards, Cortes was not perfectly easy on his part. He was sensible that he only held an usurped authority; and was afraid lest the representations of Velasquez should induce the Spanish court to recal him from the great enterprise which he had in view. To obviate these difficulties, he founded the colony of Vera Cruz, in the king's name; pretended to resign his authority into the hands of the new magistrates whom he himself had constituted, and was, as might be expected, conjured by them to resume the command. At the same time he prevailed on the magistrates of the new colony to write a letter to the king, requesting the confirmation of what they had done. Cortes himself wrote on the same occasion; and whilst he gave a most exaggerated account of the country which he was about to conquer for the crown of Spain, he was fortunate in having it in his power to accompany his representations with valuable specimens of its productions.

All his measures, however, had nearly been thwarted by the mutinous spirit of his followers. The partizans of Velasquez, several of whom were among his troops, were continually endeavouring to excite sedition; and many of his soldiers became alarmed at the prospect of the dangers which they must encounter. A conspiracy was formed in consequence against Cortes, which he had the good fortune to discover and defeat when it was on the eve of being carried into execution.

To engage his followers completely in the enterprise on which his own heart was so fully set, and to cut off the very possibility of abandoning it, he formed the resolution of destroying his fleet. It was of the utmost consequence, however, not to estrange the affections of his adherents, by any seemingly rash or despotic act originating in his own views and feelings: And his address and power over the minds of his followers are conspicuously displayed, in making them voluntarily consent to such a sacrifice. He pointed out the leaky and unserviceable state of the ships, the great accession of strength they would derive from the sailors who manned them; and above all, he pressed upon them the necessity of fixing their hopes on the rich country which lay before them. In consequence of these representations, the ships were drawn ashore, stript of their sails, rigging, iron-work, &c. and broken in pieces. And thus 500 men consented to shut themselves up in a hostile country, leaving themselves no alternative of safety but their own valour.

Several circumstances contributed to the success of Cortes, besides the superiority of European weapons, valour, and discipline. The emperor of Mexico was indeed powerful, but he was cruel and despotic, and the yoke which he had imposed on the neighbouring nations was a yoke of iron; and nothing but fear prevented them from attempting to shake it off. Cortes soon had an opportunity of discovering this; and he saw all the advantages to be derived from it. The cazique of Zempoalla sent messengers to him, imploring his assistance against the tyrant of Mexico; and Cortes removed to his capital, where he was received with every demonstration of friendship; which, however, he nearly forfeited by the imprudence of his zeal, in ordering his soldiers to destroy the idols in the chief temple of Zempoalla; and to erect an image of the Virgin Mary in their stead. This unlucky affair being adjusted, Cortes proceeded on his march towards Mexico; and was furnished by the cazique of Zempoalla with provisions, and with 200 Indians to carry burdens and perform other servile offices. This was of great consequence in a country where beasts of burden were unknown.

Nothing memorable happened till he reached the confines of Tlascala. The inhabitants of this province were a warlike people, and implacable enemies of the Mexicans. It might therefore have been expected that they would have joined Cortes: but they distrusted his professions; and as they saw him determined to visit the emperor of Mexico in his capital, they naturally concluded that it was to seek his friendship. They therefore attacked Cortes with all their forces, and with the most determined spirit of animosity. They sent a supply of provisions to the Spaniards, desiring them to eat freely, as they could have no pleasure in eating famished victims, and as such sacrifices would not be acceptable to their gods. After great efforts and incredible slaughter on the part of the Tlascalans, they were at last disposed to peace. The language of their ambassador is descriptive of the mixed feelings of terror and respect with which the Spaniards were viewed by the native Americans. "If," said they, "you are divinities of a cruel and savage nature, we present to you five slaves, that you may drink their blood and eat their flesh. If you are mild deities, accept an offering of incense and variegated plumes. If you are men, here is meat and bread, and fruit to nourish you." A peace was concluded to the satisfaction of both parties, and particularly advantageous to Cortes, as the Tlascalans remained ever after firmly attached to him, and he had reason to ascribe the conquest of Mexico chiefly to their assistance.

Having remained in Tlascala twenty days to refresh his troops, and conciliate his new allies, he proceeded on his march to Mexico, accompanied by six thousand Tlascalans. Montezuma, after much hesitation, had at last promised Cortes a personal interview, and informed him that he had given orders for his friendly reception in Cholula. It appears, however, that a deep plot had here been laid for his destruction. The Cholulans refused to admit into their town their ancient enemies the Tlascalans. They received Cortes, however, and his soldiers, with much appearance of cordiality. The Tlascalans had warned him to be on his guard; and two of them having entered the town in disguise, had an opportunity of seeing what was going on: they acquainted Cortes that the women and children of the principal inhabitants were retiring in great numbers every night, and that six children had been sacrificed in the principal temple, a certain indication that some great warlike enterprize was in contemplation. Marina, the interpreter, also had learned from a Cholulan woman, that the destruction of the Spaniards was resolved on. On this information, Cortes resolved to anticipate his enemies, and fell upon them so unexpectedly, that though preparing for his destruction, they could make no resistance, and 6000 of them were slain without the loss of a single Spaniard.

He now advanced directly towards Mexico, from which he was only twenty leagues distant, and had the satisfaction to observe, in every step of his progress, evident marks of disaffection to the Mexican government; and his own ardour and that of his men was farther kindled, when they beheld from the mountains of Chalco the vast plain of Mexico covered with cultivated fields; when they saw a lake resembling a sea in extent, encompassed with large towns, and discovered the capital itself rising on an island in the middle, adorned with turrets and temples. The whole prospect was so different from any thing they had ever seen, that they were almost disposed to think it a scene of enchantment. As Cortes approached the city, Montezuma shewed his irresolution, by sending various messengers, sometimes permitting him to advance, at other times requiring him to retire, according to the fluctuation of his feelings. Cortes paid no attention to these opposite requests, but continued his march along the causeway which led to the city, observing the greatest circumspection, but without betraying any symptoms of suspicion.

As he approached, Montezuma came out to meet him, attended by a splendid retinue, and with all the insignia of regal magnificence. He was carried in a chair or litter, richly ornamented with gold and feathers of various colours, on the shoulders of four of his principal favourites. Cortes dismounted to receive him, at the same time Montezuma alighted from his litter, and approached with a stately pace, his attendants covering the street with cotton cloths, that he might not touch the ground. Cortes accosted him in the European manner, and he returned the salutation by touching the earth with his hand, and then kissing it. This was the way in which inferiors saluted their superiors, and his subjects were astonished to see such condescension in their haughty monarch. They concluded that the persons to whom he paid such extraordinary marks of respect must be something more than human. Montezuma conducted Cortes to a lodging surrounded by a stone wall, with towers at proper distances, and its apartments and courts were sufficiently large to accommodate both the Spaniards and their Indian allies. The first care of Cortes was to provide for his security, by planting his artillery in such situations as to command the different avenues leading to the place appointed for his residence; and though Montezuma told him in the evening that he and all his dominions were subject to him, as he was convinced that the Spaniards were the powerful strangers foretold in some of their prophecies, who were to reform and new-model the Mexican state, yet Cortes observed the same vigilant discipline as if he had been in sight of the enemy's camp.

The city of Mexico was built on some small islands in an extensive lake, and was connected with the land by causeways. The situation of the Spaniards, therefore, was extremely critical, should Montezuma conceive any hostile intentions against them. It was easy to cut off their retreat, by breaking down the bridges and causeways; and with all the advantages which the Spaniards possessed, they were alarmed at the thoughts of being shut up in the city amidst sixty thousand hostile inhabitants. And it was not long till Cortes had good cause of alarm. He had learned that Escalante, whom he had left in the government at Villa Rica, had been mortally wounded in a rencontre with the Mexicans, and that one of the Spaniards being taken prisoner, his head was cut off, and after it had been carried in triumph through various cities, to show that the Spaniards were not immortal, had at last been brought to Montezuma. Cortes therefore determined to adopt a bold measure; to seize Montezuma in the midst of his capital, and carry him as a prisoner to the Spanish quarters, that he might employ his sacred authority in accomplishing the plans which he had in view; an expedient which has since been adopted, after his example, on various occasions, and with various success. He went to Montezuma, accompanied by his most determined officers, and a chosen band of soldiers: he upbraided him as the author of the unprovoked attack upon the Spaniards at Villa Rica. Montezuma asserted his innocence, and offered to bring the officer who commanded on that occasion a prisoner to Mexico. Cortes replied, that it was necessary, in order to remove the suspicions of his followers, that he should leave his palace, and take up his residence in the Spanish quarters. The Mexican prince heard the proposal with the utmost indignation, and said his people would protect him from such an insult. Cortes reasoned and remonstrated in vain; and the altercation had continued three hours, when one of Cortes's officers exclaimed, "Let us seize him instantly, or stab him to the heart." Montezuma was terrified by the fierceness of his voice and gestures, and suffered himself to be carried to the Spanish quarters, amidst the tears and lamentations of his people.

Cortes wishing to impress the Mexicans with the idea that to put a Spaniard to death was the greatest of all crimes, caused the officer who commanded against Escalante, his son, and five other principal officers, to be tried by a Spanish court martial: they were condemned to be burnt alive; the sentence was executed in the presence of the sorrowful Mexicans; and the weapons collected in the royal magazines for the defence of the state, composed their funeral pile.

Cortes completely subdued the mind of Montezuma by these proceedings, and for the space of six months made him the willing instrument of promoting his purposes. Montezuma gave orders to his people to bring part of the naval stores which the Spaniards had deposited at Vera Cruz; others were commanded to cut down and prepare timber, and by these means the Spanish carpenters were soon enabled to complete two brigantines, which gave Cortes the command of the lake of Mexico. He next prevailed on Montezuma to declare himself a vassal of the King of Spain: encouraged by this facility, Cortes proposed that he should establish by royal authority the Christian religion. But however complying he had been in other respects, he obstinately resisted this proposal. Provoked by this resistance, Cortes led out his soldiers to throw down, by force, the idols in the grand temple of Mexico. Both priests and people were instantly in arms, and Cortes's zeal was forced to yield to his prudence.

From that moment the Mexicans were determined to attempt the expulsion or destruction of the Spaniards: and Montezuma assuming unusual spirit, told Cortes that since the object of his embassy was now accomplished, it was the will of the gods, and of the people of Mexico that he and his followers should instantly depart. Amidst these transactions, a Mexican courier arrived with intelligence that some ships had appeared off the coast. Cortes fondly imagined that these brought reinforcements from Spain, and a confirmation of his usurped authority. How great was his mortification when he heard that it was a formidable armament fitted out against him by Velasquez, governor of Cuba. This armament consisted of eighteen ships, having on board eighty horsemen, eight hundred foot soldiers, a hundred and twenty cross-bowmen, and twelve pieces of cannon, and Pamphilo de Narvaez had the command. Cortes, having endeavoured to persuade Montezuma that the strangers newly arrived were his friends, with whom he must have an interview, left Pedro de Alvarado with a hundred and fifty men to take charge of Montezuma, and the Mexican capital, and marched instantly against Narvaez with about two hundred and fifty men. He negociated with his followers, held out the alluring prospects of wealth and honour, and had undermined their fidelity before he commenced the attack, which was conducted in the night, and with complete success. Narvaez was taken prisoner, and almost all his men joined Cortes.

During Cortes's absence, the Mexicans had taken up arms to expel their invaders; they had been wrought up to the highest pitch of fury, and forgetting the terrors which the Spaniards had inspired, they attacked them in their quarters, killed several of them, and destroyed their magazines, together with the two brigantines which Cortes had built to give him the command of the lake. On receiving an account of these proceedings, he hastened back to Mexico with all his forces, where he found the Mexicans burning with implacable animosity. He attacked them repeatedly without effect; though immense numbers were slain, fresh troops rushed forward to devote themselves, till the Spaniards, wearied with slaughter, were forced to retire. He next brought forward Montezuma to persuade them to cease from hostilities. Though they adored their prince, his proposal was received with so much indignation, that they discharged a volley of arrows and stones, by which the unhappy monarch was killed.

Cortes now resolved to retreat from Mexico: but finding it necessary to dislodge the Mexicans from a high tower which overlooked the Spanish quarters, he forced his way to the top of the battlements, where two young Mexicans, seizing him in their arms, threw themselves from the tower, in the hopes of dragging Cortes along with them. He disengaged himself by his strength, and the gallant youths perished in endeavouring to deliver their country.

The Spaniards now prepared for a precipitate retreat, which they resolved to attempt in the dead of night, with a view to elude the vigilance of the Mexicans. Their motions, however, had been carefully watched, and whilst they were proceeding silently along the causeway, they were suddenly alarmed by the warlike shouts of the Mexicans, and assailed with innumerable weapons. The conflict became tremendous. Cortes effected his retreat, the bodies of the slain serving as a bridge across the breaches in the causeway; and when he mustered his forces next day, he found that he had lost many of his best officers, half his followers, all his artillery, and almost all his horses. He continued his retreat towards the territories of the Tlascalans, being continually harassed by the Mexicans, who were defeated in a great battle at Atumba. The Tlascalans still retained their animosity against the Mexicans, and burned to revenge the death of their countrymen who had fallen in the service of Cortes.

Notwithstanding of his disasters, Cortes determined to persist in his design of conquering Mexico. Fortune seconded his views; an avowed enemy sent forces to destroy him, an envious rival endeavoured to supplant him; he managed to seduce the forces of both, and to attach them to his service. With these reinforcements, and ten thousand Tlascalans, he marched again towards Mexico, six months after his retreat from that city. His first care was to build vessels, to give him the command of the lake. The Mexicans easily perceived the advantage which this would give him; and therefore their first attack was directed against his fleet of brigantines. Guatimozin the reigning emperor, the nephew and son-in-law of Montezuma, hoping to supply by numbers what he wanted in force, collected such a multitude of canoes as covered the face of the lake. The whole armament, however, was dissipated with such slaughter, that the Mexicans found themselves still more inferior on this new element, than they had hitherto been on land.

Cortes at first proceeded slowly and cautiously in his operations, till disconcerted by the length and difficulties of the siege, he resolved to attempt to take the city by storm. A general assault was ordered; the Spaniards advanced with impetuosity, bearing down all opposition. Cortes had taken the precaution to secure a retreat if necessary, and for this purpose appointed one of his captains to fill up the canals and gaps of the causeway, as the main body advanced. But this officer, thinking it inglorious to be thus employed whilst his companions were pressing on to victory, neglected the important trust committed to him, and hurried on to mingle with the combatants. Guatimozin, with the skill of an experienced general, instantly profited by this mistake. He ordered the troops in front to slacken their efforts, to allure the Spaniards to push forwards, whilst he dispatched a large body of chosen troops to take possession of the great breach in the causeway which had been left open. As soon as this movement was completed, the priests struck the great drum consecrated to the god of war, when the Mexicans in front rushed upon their assailants with irresistible impetuosity, and forced them back to the causeway, where their retreat was cut off. All Cortes's efforts were now directed to save such of his men as were precipitated into the breach. He himself narrowly escaped being taken, having been seized by six Mexican captains, who were hurrying him off in triumph. From this perilous situation he was rescued by two of his officers, at the expence of their own lives: but he lost sixty Spaniards, forty of whom fell alive into the hands of the enemy who, on the approach of night, were sacrificed to the god of war, within sight and hearing of the Spanish troops, whose minds were filled with indescribable horror.

The heads of the sacrificed Spaniards were sent to the principal men in the adjacent provinces, with an assurance that the god of war had declared with an audible voice, that every Spaniard should be destroyed in eight days. This prediction was universally believed; and Cortes found himself almost entirely deserted by his Indian confederates. He was therefore compelled to suspend all military operations till the fatal period should elapse; when the Indians, convinced that the god of war had deceived the Mexicans, returned with greater confidence than ever to their alliance with Cortes, who, according to his own account, soon found himself at the head of a hundred and fifty thousand Indians. By his brigantines and his numerous Indian auxiliaries, he was now enabled to shut up the city so completely, that famine began to make dreadful ravages amongst the besieged. The Mexican nobles advised Guatimozin to retire from a place which now appeared untenable; the Spaniards being already in possession of nearly three-fourths of the city. To accomplish this purpose, they endeavoured to deceive Cortes by various proposals of submission; but he was too vigilant to be deceived; Guatimozin was taken in attempting to escape across the lake; and with him fell the city and empire of Mexico. See Mexico.

Cortes had all along acted without any authority from the court of Spain; and after he had completed the reduction of Mexico, an officer was sent to supersede him, to confiscate his effects, and examine into his conduct. The person entrusted with this commission was a man of no talents; and being conscious of his weakness, he abandoned a country which he was unworthy to govern. Cortes's authority was at last confirmed by a warrant from the crown, and he was appointed captain-general and governor of New Spain. His enemies, however, still continued to plot against him, and misrepresented his conduct so grossly, that Charles was induced to order a solemn inquest into his conduct, to seize his person, and to send him, if that should be thought expedient, a prisoner to Spain. Cortes disdaining to stand a trial in a country which was filled with the glory of his exploits, resolved instantly to return to Spain, and there face his accusers.

His appearance in Spain removed every doubt that had been entertained with respect to his intentions. He appeared surrounded with all the splendour which fame and riches can confer: the emperor received him with the highest marks of distinction and respect; conferred upon him the order of St Jago, the title of Marquis *del Valle de Guaxaca*, together with the grant of an ample territory in New Spain; and as his manners were correct and elegant, the emperor admitted him to the same familiar intercourse with himself that was enjoyed by noblemen of the first rank.

But though Cortes was thus distinguished, the emperor was not fond of entrusting such extensive power in the hands of a man whose influence might be dangerous. Cortes therefore returned to Mexico, dignified with new titles, but with diminished authority. The supreme direction of civil affairs was placed in a board called the *Audience of New Spain*; the military department, with powers to attempt new discoveries, were left in the hands of Cortes. This division of authority cramped the efforts, and embittered the life of Cortes. His zeal for new discoveries remained, however, unabated. Having fitted out an armament, he took the command in person, and after enduring incredible hardships, discovered the large peninsula of California. Cortes had a considerable time before traversed an immense tract of country to punish the treachery of Christoval de Olid, one of his principal officers, who had attempted to establish an independent authority. In this expedition he marched three thousand miles, through a country abounding with thick forests, rugged mountains, deep rivers, thinly inhabited, and almost wholly uncultivated. He was engaged in this dreadful service above two years; and though it was not distinguished by any splendid event, he displayed during the course of it, greater personal courage, more fortitude of mind, more patience and perseverance, than in any other period or scene of his life.

Finding himself exceedingly uncomfortable in Mexico, he returned to Spain to seek the redress of his grievances. The fame of new adventurers had now engaged the public attention, and Cortes died neglected, in the year 1547, in the sixty-second year of his age.

His character is thus drawn by Dr Robertson: "The turbulence of youth, as soon as he found objects and occupations suited to his mind, gradually subsided and settled in a habit of regular, indefatigable activity. The impetuosity of his temper, when he came to act with his equals, insensibly abated, by being kept under restraint, and mellowed into a cordial, soldierly frankness. These qualities were accompanied with calm prudence in concerting his schemes, with persevering vigour in executing them, and with what is peculiar to superior genius, the art of gaining the confidence and governing the minds of men. To all which were added, the inferior accomplishments that strike the vulgar, and command their respect; a graceful person, a winning aspect, extraordinary address in martial exercises, and a constitution of such vigour as to be capable of enduring any fatigue." (*v*)

CORTESIA, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 177.

CORTONA, a town of Italy, is finely situated on the side of a mountain, about 30 miles south-east of Sienna. It is supposed to be the most ancient town in the country, and still retains its original name. The principal public buildings are seven churches, a museum, a public library, an academy, and twelve convents for both sexes. Some of the churches are handsome, and contain many valuable paintings. The object of the academy, which has obtained great reputation, is to discover and elucidate Etrurian antiquities. The ancient walls of Cortona were built of large blocks of stone without cement, and several remnants of them are still in great preservation. See Eustace's *Classical Tour through Italy*, vol. ii. p. 190. (π)

CORTUSA, a genus of plants of the class Pentandria, and order Monogynia. See Botany, p. 136.

CORUNNA, a sea-port town of Spain, in the province of Galicia. It is situated on a peninsula at the entrance of the bay, which stretches into the land as far as Betanzos. Corunna is divided into the upper and lower, or the new and old town. The old town, which is called *Pecaria* and *Pescaria*, is situated upon a tongue of land, which is surrounded by the sea almost up to the high town. The new town, which is situated on the declivity of a mountain, is inclosed by walls, and defended by a citadel. Its streets are narrower and worse paved than those of the old town.

The principal public buildings are St James's and St Mary's churches in the old town, and St Nicholas's and St George's in the new town; four convents, six chapels, one hospital for sailors, and another for the town's people. Besides these, there are artillery and naval schools, an arsenal, a storehouse for ammunition, an armoury, a powder magazine, and an aqueduct. There are also three squares in Corunna. The ancient tower is particularly deserving of notice, both from its height, and from the strength and solidity of its walls.

The harbour of Corunna, which is excellent, is in the form of a crescent, and has a handsome and convenient quay, which extends the length of the anchorage. It is sheltered from the north wind by a small island, and is defended by the forts St Claire and St Martins. The forts St Amaro and St Antonio defend the entrance to the harbour. The latter of these, which serves for a state prison, is placed upon a steep rock, and commands the harbour and the bay. The principal manufactories in Corunna, are of calicoes, table linen, hats, lace, combs, and ropes. The hat manufactory employed 150 people, who made about 20,000 hats annually for the interior of Spain. The rope walk employs 70 workmen, and cables are made from 120 to 160 fathoms. The commerce of Corunna is considerable. A light-house is erected on a lofty mountain about a league from the harbour. Population 4000. West Long. 8°, North Lat. 43° 23′. (π)

COS. See Stanchio.

COSENZA, a city of Italy, in the kingdom of Naples, and the principal town of Calabria Citra. It is situated near the southern extremity of a spacious plain, upon seven hills, at the distance of about twelve miles from the Tuscan Sea; and is surrounded by several villages called Casalis. The extent of the town is nearly three miles: the streets are in general straight, and the houses ill built, and there is only one of the streets that is distinguished by handsome edifices. The castle is finely situated on an eminence above the confluence of the rivers Busiento and Crathis, over which there are bridges. The cathedral, or metropolitan church, is a large massy and venerable edifice, and is the only church within the walls. In a church at the side of the castle there are two or three paintings, which appear to be of the school of Raphael. The three hundred and thirty-six casalis which encircle Cosenza contribute greatly to embellish the town, particularly on the south. They originated in the tenth century, about the year 975, when the Saracens took and destroyed Cosenza. The inhabitants who remained sought for refuge among the mountains, and the casalis gradually increased to their present size. Cosenza is also embellished by the junction of the Crathis and the Busiento, which is unfortunately the cause of the bad air that is often so injurious to the inhabitants, from the marshes left by the inundation of the adjacent grounds. There are almost no objects of antiquity at Cosenza. M. Bartels sought in vain for the place where Alaric, the chief of the Visigoths, was buried in 422. It is said that the Goths, by means of their prisoners, turned the course of the Busiento at its junction with the Crathis, and that they interred their king, with all his treasures, in the bed of the river; and in order that the place might never be discovered, they slew all the prisoners who were employed, and conducted the river into its former bed. M. Bartels found some columns which appeared to be the remains of an ancient temple. A small Hercules in bronze, and a Greek medal, were the only other antiquities which he saw. The royal tribunal, which sits at Cosenza, brings to the town a number of persons who have causes to decide, besides the governor, the assessors of the tribunal, and a crowd of advocates. The annual fair which is held here, and which had its origin in the time of Frederick II. is also of great advantage to the town, as it attracts numbers of people from the surrounding provinces. The earthen ware which is made in this place, forms its principal branch of industry. A number of small articles of iron, particularly knives, are likewise manufactured here. The people are nevertheless very poor and discontented. The adjacent country is beautiful and well cultivated, and produces abundance of corn, fruit, wine, oil, and silk. The grand forest of Sila, which covers a surface of 400 miles, commences near Cosenza, and extends almost to Catanzaro in Calabria Ultra. There are mines of salt in the neighbourhood of Cosenza, but they are not wrought, lest they should interfere with the manufacture of sea salt at Naples. Cosenza appears at first to be very populous, but this deception arises from the great number of the inhabitants of the casalis, who daily flock to the town. Swinburne estimates the population so low as 9000; but M. Bartels, who has visited the town more recently, computes the population at 15 or 16,000. East Long. 16° 22′, North Lat. 39° 22′. See Swinburne's *Travels*, and Bartels' *Voyage dans la Calabrie et la Sicile*. (π)

COSMIBUENA, a genus of plants of the class Pentandria, and order Monogynia. See BOTANY, p. 176.

COSMOGONY, means an account of the creation of the world. Various cosmogonies are detailed by different authors. Moses's is unquestionably the most ancient; and had it no other circumstance to recommend it, its superior antiquity alone would give it a just claim to our attention. It is evidently Moses's intention to give a history of man, and of religion, and an account of creation. In the way in which he has detailed it, it would have been foreign to his plan, had it not been necessary to obviate that most ancient and most natural species of idolatry, the worship of the heavenly bodies. His first care, therefore, is to affirm decidedly, that God created the heavens and the earth; and then he proceeds to mention the order in which the various objects of creation were called into existence. First of all, the materials, of which the future universe was to be composed, were created. These were jumbled together in one indigested mass, which the ancients called chaos, and which they conceived to be eternal; but which Moses affirms to have been created by the power of God. The materials of the chaos were either held in solution by the waters, or floated in them, or were sunk under them; and they were reduced into form, by the spirit of God moving upon the face of the waters. Light was the first distinct object of creation; fishes were the first living things; man was last in the order of creation.

We deem it unnecessary to enter into a more minute detail on a subject, which must be familiar to all our readers; and we should reckon it presumptuous to amuse them with theories, where every thing is recorded as a matter of fact, and where the modes and order of creation, are ascribed to the will of the Deity, as their immediate cause. The account given by Moses is distinguished by its simplicity. That it involves difficulties which our faculties cannot comprehend, is only what might be expected, from a detail of the operations of the omnipotent mind, which can never be fully understood but by the being who planned them.

Most of the writers who come nearest to Moses in point of antiquity, have favoured the world with cosmogonies; and there is a wonderful coincidence in some leading particulars between their accounts and his. They have all his chaos; and they all state water to have been the prevailing principle, before the arrangement of the universe began. The systems became gradually more complicated, as the writers receded farther from the age of primitive tradition; and they increased in absurdity, in proportion to the degree of philosophy which was applied to the subject. The problem of creation has been said to be, "Matter and motion given to form a world;" and the presumption of man has often led him to attempt the solution of this intricate problem. At first, the cosmogonists contented themselves with reasoning on the traditional or historical accounts they had received; but it is irksome to be shackled by authority; and after they had acquired a smattering of knowledge, they began to think that they could point out a much better way of forming the world, than that which had been transmitted to them by the consenting voice of antiquity. Epicurus was most distinguished in this hopeful work of reformation; and produced a cosmogony on the principle of a fortuitous concourse of atoms, whose extravagant absurdity has hitherto preserved it from oblivion. From his day to the present, the world has been annoyed with *systems of creation*, which are at present swallowed up by the geological theories of chemists and mineralogists, whose speculations, in so far as they proceed on the principle of induction, have sometimes been attended with useful results; but when applied to solve the problem of creation, will serve, like the systems of their forerunners, to demonstrate the ignorance and the presumption of man.

The early cosmogonies are chiefly interesting from their resemblance to that of Moses; which proves that they have either been derived from him, or from some ancient prevailing tradition respecting the true history of creation.

The most ancient author next to Moses, of whose writings any fragments remain, is Sanchoniatho the Phenician. His writings were translated by Philo Byblius; and portions of this version are preserved by Eusebius. These writings come to us rather in an apocryphal form; they contain, however, no internal evidence which can describe their authenticity: they pretty nearly resemble the traditions of the Greeks, and are, perhaps, the parent stock from which these traditions are derived. Sanchoniatho, according to the most accurate chronology, was about 300 years later than Moses; and he professes to collect the opinions, traditions, and histories of the Phenicians respecting the cosmogony, and the first ages of the world. According to these accounts, chaos, and a spirit, or air, were the origin of all things. Φοινικων θεολογια την των όλων αρχην υποτιθεται αερα ζοφωδη και πνευματωδη, η πνοην αερος ζοφωδους, και χαος θολερον, ερεβωδες. He then proceeds to describe the manner in which creation commenced. The spirit fell in love with its own principles; in consequence of which there was a commixtion; and the new combination was called ποθος, Desire or Cupid. Having thus obtained a kind of tangible agent, who has great efficiency in all the systems of ancient mythology, the work of creation proceeded with great ease and expedition. We do not pretend to understand this; we only profess to translate; and our learned readers may ascertain the accuracy of our comment, by comparing it with the original; *οτε δε ηρασθη το πνευμα των ιδιων αρχων και εγενετο συγκρασις, ἡ πλοκη εκεινη εκληθη ποθος, αὑτη δε αρχη κτισεος απαντων.* As far as this system can be understood, it appears to be atheistical, at least its object seems to be, to show that the gods, as well as every thing else, had a beginning from some necessity of nature. In this respect it is directly, and in all probability, purposely opposed to that of Moses; in other respects, there is a striking resemblance, and it seems to have been copied from the Hebrew prophet, with such modifications as suited the pagan notions of the author. We have, however, a dark chaos, and a spirit, which, by a certain operation, affected this mass, and gave birth to creation. It would be needless to point out the resemblance between this idea, and that which is expressed in the second verse of the first chapter of Genesis. "*The earth was without form and void, and darkness was upon the face of the deep; and the spirit of God moved upon the face of the waters.*" The nonsense which is spoken about *ποθος* or Desire being produced by some mysterious agency of the spirit, has, in all probability, arisen from the Hebrew word translated *moved* in the verse now quoted; and which strictly signifies the affectionate fluttering of a bird over its young; or the incubation of a pigeon on its eggs: and hence also, the origin of the *mundane egg*, which makes such a conspicuous figure in various cosmogonies.

The notions detailed by Sanchoniatho are almost translated by Hesiod, *in Theogon.* who mentions the primeval chaos, and states *ερος* or Love to be its first offspring.

Anaxagoras was the first among the Greeks who entertained tolerably accurate notions on the subject of creation: he assumed the agency of an intelligent mind in the arrangement of the chaotic materials. *παντα χρηματα ην ὁμου πεφυρμενα ὁ νους δε αυτα διηρε και διεκοσμησε, και εκ της ατοξιας ες ταξιν ηγαγε.* These sentiments gradually prevailed among the Greeks; from whom they passed to the Romans, and were generally adopted, notwithstanding the efforts which were made to establish the doctrines of Epicurus by the nervous poetry of Lucretius. Ovid has collected the orthodox doctrines which prevailed on the subject, both among Greeks and Romans; and has expressed them with uncommon elegance and perspicuity in the first chapter of his Metamorphoses. There is the most striking coincidence between his account and that of Moses: one would almost think that he was translating from the first chapter of Genesis; and there can be no doubt that the Mosaic writings were well known at that time, both among the Greeks and Romans. Megasthenes, who lived in the time of Seleucus Nicator, affirms, that all the doctrines of the Greeks respecting the creation, and the constitution of nature, were current among the Bramins in India, and the Jews in Syria. *Clemens. Alex. Strom.* l. i. He must, of course, have been acquainted with the writings of the latter, before he could make the comparison. Juvenal talks of the writings of Moses as well known.

Tradidit arcano quodcunque volumine Moses.

We are therefore inclined to think that Ovid actually copied from the Bible; for he adopts the very order detailed by Moses. We call the attention of our readers to this curious subject. Moses mentions the works of creation in the following order; the separation of the sea from the dry land—the creation of the heavenly bodies—of marine animals—of fowls and land animals—of man. Observe now the order of the Roman poet.

Ante mare et terras, et quod tegit omnia cœlum
Unus era toto naturæ vultus in orbe,
Quem dixere chaos, rudis, indigestaque moles.—
Hanc Deus, et melior litem natura diremit.
Nam cœlo terras, et terras abscidit undis;
Et liquidum spisso secrevit ab aere cœlum.—
Neu regio foret ulla suis animalibus orba,
Astra tenent cœleste solum, formæque deorum;
Cesserunt nitidis habitandæ piscibus undæ:
Terra feras cepit, volucres agitabilis aer.
Sanctius his animal, mentisque capacius altæ
Deerat adhuc, et quod dominari in cætera posset:
Natus homo est.

Here we see all the principal objects of creation mentioned exactly in the same order which Moses had assigned to them in his writings: and when we consider what follows; the war of the giants; the general corruption of the world; the universal deluge; the preservation of Deucalion and Pyrrha; their sacrifice to the gods on leaving the vessel in which they had been preserved; there can scarcely remain a doubt that Ovid borrowed, either directly or at second hand, from Moses. What he says too, is perfectly consistent with the received notions on the subject, though it is probable that they had never before been so regularly methodised. This train of reasoning would lead us to conclude that Ovid, and indeed the whole heathen world, derived their notions respecting the creation, and the early history of mankind, from the sacred scriptures; and it shows how deficient their own resources were, when the pride of philosophy was forced to borrow from those whom it affected to despise.

With regard to the Western mythologists, then, there can be little doubt that their cosmogonies, at least such of them as profess to be historical, and not theoretical, are derived from Moses: and the same may be affirmed with regard to the traditions of the East; as they were the same with those of Greece, in the time of Megasthenes, whose testimony to this effect is quoted both by *Clemens Alex.* and *Strabo*, l. xv. we may naturally conclude that they had the same origin. The Hindoo mythology has grown, in the natural uninterrupted progress of corruption, to such monstrous and complicated absurdity, that in many cases it stands unique in extravagance. In the more ancient Hindoo writings, however, many sublime sentiments occur; and in the *Institutes of Menu*, many passages are found relating to the creation, which bear a strong resemblance to the account given by Moses. A writer in the Asiatic researches has been at the pains to collect these passages; and, deceived by the imagined antiquity of the work, he takes leave of the subject in a very extraordinary manner, by saying, that it is not his business to decide whether the Hindoos borrowed from Moses, or Moses from the Hindoos. There is yet another alternative: it is evident that the history of creation could only be communicated by revelation from heaven; for no man was present to see it; but it may justly be doubted whether Moses was the only person to whom this revelation was imparted. There is every reason to suppose that Adam, and all the antediluvian and postdiluvian patriarchs, had the knowledge of this event, acquired either by inspiration, or tradition, which they would naturally communicate to their families and dependents, and thus diffuse it over the face of the earth: and whilst Moses gave a correct and true account under the guidance of inspiration; others, receiving their information, through the uncertain channel of tradition, might give accounts bearing various shades of resemblance to the truth. (See ANTEDILUVIANS.) We are not under the necessity then, of supposing that even the heathen have borrowed from Moses when their accounts approximate the truth; except when the resemblance is so striking that it cannot be accidental; though there is every reason to think that they have borrowed much more frequently than is generally supposed.

The writer alluded to above was cured of his scepticism, so far at least as to confess that he had been deceived as to the great antiquity of the Indian record, on which he had laid so much stress as to set it in this respect on a footing of equality with the Bible. The passages relating to the creation, however, are curious; and the work from which they are taken is unquestionably ancient: they exhibit striking features of the Mosaic account, blended with the refinements of metaphysical philosophy. They are thus given in an advertisement, prefixed to the fifth volume of the Asiatic Researches, and are intended as a supplement to a former treatise on the Hindoo religion.

"This universe existed only in the first divine idea, yet unexpanded, as if involved in darkness, imperceptible, undefinable, undiscoverable by reason, and undiscovered by revelation, as if it were wholly immersed in sleep. (ch. i. 5.)

"When the sole self-existing power, himself undiscerned, but making this world discernible, with five elements and other principles of nature, appeared with undiminished glory, expanding his idea, or dispelling the gloom. (ib. 6.)

"He, whom the mind alone can perceive, whose essence eludes the external organs, who has no visible parts, who exists from eternity, even he, the soul of all beings, whom no being can comprehend, shone forth in person. (ib. 7.)

"He, having willed to produce various beings from his own divine substance, first with a thought created the waters. (ib. 8.)

"The waters are called *nara,* because they are the production of Nara, *or the spirit of God*; and since they were his first *ayana, or place of motion,* he thence is called Narayana, or *moving on the waters.*

"From *that which is,* the first cause, not the object of sense, existing every where in substance, not existing to our perception, without beginning or end, was produced the divine male. (ib. 11.)

"He framed the heaven above, and the earth beneath: in the midst he placed the subtile ether, the eight regions, and the permanent receptacle of waters. (ib. 13.)

"He framed all creatures. (ib. 16.)

"He too first assigned to all creatures distinct names, distinct acts, and distinct occupations. (ib. 21.)

"He gave being to time, and the divisions of time, to the stars also and the planets, to rivers, oceans, and mountains; to level plains, and uneven vallies. (ib. 24.)

"For the sake of distinguishing actions, he made a total difference between right and wrong. (ib. 26.)

"Having divided his own substance, the mighty power became half male, half female. (ib. 32.)

"He whose powers are incomprehensible having created this universe, was again absorbed in the spirit, *changing the time of energy for the time of repose.*" (ib. 56.)

In these passages, we have evidently a philosophical comment on the account of creation as given by Moses; or as transmitted from one generation to another by oral tradition: and it would not detract in the least degree from the credit of Moses, were we even to suppose the Hindoo account to be more ancient than his; of which, however, there is not the shadow of probability.

We also see in these passages the rudiments of the Platonic philosophy, *the eternal ideas in the Divine mind,* &c.; and were any question to arise respecting the original author of these notions, we should have little hesitation in giving it against the Greeks. They were the greatest plagiaries both in literature and philosophy, and they have scarcely an article of literary property which they can call their own, except their poetry. Their sages penetrated into Egypt and India, and on their return stigmatised the natives of these countries as barbarians, lest they should be suspected of stealing their inventions. The same principle led both Egyptians and Indians to conceal the source from which they derived their knowledge, and to appropriate to themselves all the information which they had gleaned by their intercourse with more enlightened people. Hence the extravagant pretensions of both these nations to antiquity, both as to their literary productions and their political establishments; pretensions which now shrink into very limited dimensions, and excite the derision rather than the wonder of the learned.

After the account which has been given of the principal systems of cosmogony, and of their respective merits, it will not be necessary to dwell long on those which are formed on similar principles. The Chaldean cosmogony, according to Berosus, in his *Babylonica,* as preserved by Syncellus, when divested of allegory, seems to resolve itself into this, that darkness and water existed from eternity; that Belus divided the humid mass, and gave birth to creation; that the human mind is an emanation from the divine nature.

The cosmogony of the Persians is very clumsy in its structure. They introduce two eternal principles, the one good, called Oromasdes, the other evil, called Arimanius; and they make these two principles contend with each other in the creation and government of the world. Each has his province, which he strives to enlarge, and Mithras is the mediator to moderate their contentions. This is the most inartificial plan that has been devised to account for the existence of evil, and has the least pretensions to a philosophical basis.

The Egyptian cosmogony, according to the account given of it by Plutarch, seems to bear a strong resemblance to the Phenician, as detailed by Sanchoniatho. According to the Egyptian account, there was an eternal chaos, and an eternal spirit united with it, whose agency at last arranged the discordant materials, and produced the visible system of the universe.

The cosmogony of the northern nations, as may be collected from the Edda, supposes an eternal principle prior to the formation of the world.

The Orphic Fragments state every thing to have existed in God, and to proceed from him. The notion implied in this maxim is suspected to be Pantheistic, that is, to hold the universe to be God.

Plato supposed the world to be produced by the Deity, uniting eternal immutable *ideas*, or *forms*, to variable matter.

Aristotle had no cosmogony, because he supposed the world to be without beginning and without end.

According to the Stoical doctrine, the divine nature acting on matter, first produced moisture, and then the other elements, which are reciprocally convertible. See Shuckford's *Connections*; Grotius *De Veritat. Relig. Christ.* l. 1.; Enfield's *History of Philosophy*; and the books already mentioned in this article. (*g*)

COSSACKS, or KOZAKS, a military nation inhabiting the frontiers of the Russian empire, and constituting its principal defence against the incursions of the Tartars and other savage tribes.

Origin and history.

The origin of this people has never been completely ascertained. Some maintain that they are of Polish extraction, and that their language is a dialect of the Polonese;* while others trace their emigration from the country of Casachia, a part of the modern Circassia, lying in the vicinity of Mount Caucasus. This country is distinctly mentioned by Constantine Porphyrogenetes, and it is from hence that they are said to have derived their name.† Their history, as given by themselves, fixes their origin to be a mixture of Circassians and Greeks, afterwards augmented by strangers from various nations. According to their own account, their capital was founded by refugees from Greece, who, having been denied admission by the people of Azof, proceeded up the river, and established a new settlement, to which they gave the name of Tcherchaskoy, implying "the small village of the Tcherchas," or according to our orthography, Circassians, on whose frontier it was situated, and by whom its population was soon increased. This colony was the original stem, from which has sprung these innumerable hordes, which have now penetrated into almost every division of the Russian empire. The circumstance which has led to the erroneous notion that they are of Polish origin is thus given by Dr Clarke. "Those of the Don relate, that a party of Cossacks being engaged in their usual occupation of hunting, near the range of Mount Caucasus, met a number of people, with whom they were unacquainted, going towards the East; and having enquired who they were, the strangers answered, that they were emigrants from Poland, who had fled the oppression of their nobles, and were proceeding to Persia, to join the troops of that country against the Turks. The Cossacks told them that they might spare themselves the trouble of so long a march in order to commit hostilities upon the Turks, and persuaded them to return with them to the town of Tcherchaskoy, where they would find an asylum, and whence, in concert with them, they might attack the fortress of Azof. Assisted by this reinforcement, and with only four pieces of cannon, all the artillery they possessed at that time, they laid siege to Azof, which fell into the hands of the combined forces." This was their first appearance as a warlike nation; and to their success in this enterprize, must be attributed that fondness for war, by which they have been since so greatly distinguished. About the middle of the tenth century, they were employed as mercenaries by the Greek emperor in his war against the Turks; and in consideration of their important services, he sent them with assurances of protection and recommendatory letters to the king of Poland. They had early begun an intercourse with the people of that country, and the frequent emigrations of the Poles had added to their number and their strength. It was indeed a law in their constitution, that whosoever chose to settle among them, even their prisoners of war, were admitted into all the privileges of citizenship. Russians, Poles, Tartars, Circassians, Calmucks, Armenians, Greeks, and Turks, were received without distinction; and thus the Cossack nation may be considered as a mixture of various tribes, united by a similarity of disposition, and forming, by reason of their government and manners, a distinct class in society. They were first employed in the Russian armies in 1579; and, after the demolition of the Tartarian empire, were appointed by the Russian government the guardians of the new frontiers. They had certain lands allotted to them for their support, and obtained a constitution, which included various privileges unknown to the other subjects of the Russian empire. Their numbers, however, so rapidly increased, that they have been compelled to seek for other settlements; and their colonies extend from the banks of the Dnieper to the remotest confines of Siberia. The Cossacks are in modern times known under various appellations, but of these the Don Cossacks may be regarded as the principal stock; and it is to them that we intend chiefly to confine the present article, contenting ourselves with a brief account of its different branches.

Soil and agriculture.

The country of the Don Cossacks is bounded by the governments of Saratof, Caucasus, Voronetz, and Ekaterinoslaf; and is upwards of 3600 square miles in extent. The soil is in general rich and fruitful, and well adapted for agriculture or pasture. The immense *steppes* which lie between the Don and the Danaetz, present, in summer, one wild continued meadow, full of flowers, and producing the richest herbage. But many of these plains are desolate and untenanted, except by beasts of prey. Cultivation is unpardonably neglected; the grass is allowed to rot upon the ground, and the only appearance of culture is confined to the banks of the rivers. The indolence and unsettled military life of the Cossacks, indeed, preclude all hope that they will ever take advantage of their fine situation, and apply themselves to the labours of husbandry. The want of towns, where they might convert their produce into money, is also another very considerable obstacle to every kind of agricultural improvement. Many of them have farms on which they maintain from 50 to 200 horses, as many horned cattle, and several hundred sheep. But the principal branch of husbandry among the more wealthy, is the cultivation of the vine. This, however, is attended with some difficulty, as the vines must be buried during the winter, to protect them from the frost, and dug up in the spring. The vineyards are chiefly planted on the southern declivity of the heights and banks of the Don, in a marly and calcareous soil; and the grapes arrive very early at maturity. The wine that is produced from them is sometimes uncommonly good, resembling something between Burgundy and Champagne, but in general it is very poor and tasteless.

* Scherer *Tableau de la Petite Russie*, tom. 1.

† Peyssonnel *Observations Historiques, &c. sur les Peuples Barbares*, p. 125. Their name has given rise to many absurd etymologies. Some derive it from a Tartar word signifying *an armed man*; others from a Polish word *Cosa*, implying a goat, either from their nimbleness, or because they formerly wore the skins of that animal; others from *Kossa*, a small promontory; and others from a word signifying a *Rover*; but the most probable is that of Peyssonnel, given in the text.

Cossacks. It is both white and red; and "if they would suffer the grapes to ripen," says Dr Clarke, "and knew the best art of preparing it, it would certainly surpass all the wines in the world, so rich and generous are the grapes affording it." For several miles round Tcherchaskoy, there are many excellent orchards, well stocked with apples, pears, peaches, plums, &c.; and in their gardens they raise melons, cucumbers, and all kinds of kitchen stuffs. Most of the towns and villages are built upon the edge of the rivers, below the level of the plain, and are so concealed by the banks, that a stranger crossing the country might suppose himself in a desert, and yet be in the midst of habitations.

Rivers. The principal of these rivers are the Don, Danaetz, Choper, Medveditz, Havla, Bouzoulook, Sal, and Manhytch. Don. The Don, according to Dr Clarke, resembles the Nile in almost all its characteristics. It has the same regular annual inundation, the same aquatic plants, the same tall flags, reeds, and bulrushes, sometimes rising to the height of twenty feet; and falls into the sea by a plurality of mouths, forming several small islands, as in the Delta, filled with fens and morasses. It rises in the government of Rezan, near Tula, from the Ivan Ozevo Lake, or St John's Sea, and after a course of about 660 miles, falls into the Sea of Azof. Its bed is generally formed of sand, marl, and lime, without either rocks or stones of any size; and during the inundations, from the middle of April to the end of June, it is of sufficient depth for ships of burden as high as Woronetz; but during the rest of the year it is so low, that upon several of the shallows the water is scarcely eighteen inches deep. The Donetz, or more Danaetz. properly the Danaetz, takes its rise in the government of Kursk, and is navigable as far as the Isum. It falls into the Don about forty-six miles above Tcherchaskoy, and receives the name of the Northern Danaetz, to distinguish it from one of the arms of the Don which takes a north-westerly direction a few miles below the fortress of Rastof, and which is called the Dead Danaetz; from a supposition that has existed from time immemorial, that the Danaetz, at this place, separates itself again from the Don. From this circumstance, Dr Clarke is of opinion, that the Tanais of the Greeks is the same as the Danaetz of the Cossacks, the change from D to T being a very common modification in language; and that the Greeks, when steering along the shore from the Crimea, having first entered into this arm of the Don, gave the name of it to the whole river. The banks of these rivers are in many places finely wooded with forests of pines and oaks, and the rivers themselves abound with plenty of excellent fish, in the greatest variety and perfection. Among these, the principal is the *beluga*, the largest eatable fish known. It resembles a sturgeon in shape, and has been seen fifty-six feet long, and eighteen feet thick, though in the Don it seldom exceeds twelve feet in length. There are also sturgeon, sterlet, trout, rudak, Prussia carp, tench, pike, perch, water-tortoises, and craw-fish of an enormous size, sometimes indeed as large as our lobsters.

Quadrupeds. The immense steppes of the Don are inhabited by innumerable animals. Besides the wolf and the bear, is the *biroke*, which is of a grey colour, with a long full tail hanging to the ground. It is about the size of a wolf, and has some resemblance to that animal; but is so ferocious that it will attack a man. It is hunted by the Cossack peasants, armed with lances, and on horseback. But the most numerous class of quadrupeds in these plains is of a smaller race, of which the most remarkable are the *suroke* and *sustic*. The former is the arctomys bobac of zoologists, and is about the size of a large badger, of a greyish-brown colour. Its head, teeth, and mouth, are like those of a squirrel, but its eyes are round, dark, and bright, and its ears rather shorter. It has a large protuberant belly, a short tail, and its paws resemble very much the hands of a man. It burrows in the earth with amazing rapidity, where it remains in a state of torpor during the half of the year; and, in general, makes such extensive subterraneous chambers, that the land is destroyed wherever it is found. Its voice resembles the grunting noise of a guinea-pig; and, when pleased or frightened, it utters short and loud squeaks like a person whistling. Many of these animals are kept tame in the houses of the peasants, but they invariably retire to their burrows in September, and never appear again until about the beginning of April. The *sustic* is a much smaller animal, and is supposed to be the *mus citillus* of Buffon. It, however, resembles the suroke in many of its habits. It makes the same whistling noise, and burrows in the earth with great quickness; but it is not supposed to sleep the half of the year, as it collects a hoard of provisions for the winter. It is a beautiful little creature, about the size of a weazel, and its colour is thus described by Dr Clarke: "All the upper part of its body is of a deep yellow, spotted with white. Its neck is beautifully white; the breast yellowish, and the belly a mixed colour of yellow and grey: it has, moreover, a black forehead, reddish-white temples, and a white chin. The rest of its head is of an ash-coloured yellow; and the ears are remarkably small." Sustics are a favourite food of the Calmucks, but are seldom eaten by the Cossacks; and are found in such swarms near the Don, that they may be taken in almost any number. Among the birds of these steppes may be mentioned those called Birds. *staritchi*, or elders, which are about the size of a snipe, of a brown colour, and very elegant form, and are held by the Cossacks in superstitious veneration.

Tumuli. Ancient sepulchral hillocks, or *tumuli*, are scattered all over the country; but they increase both in number and size towards the Don and the Sea of Azof. Some of them which have been opened by the Cossacks, were found to contain bones of men and horses, earthen vessels, and instruments of war common to ancient nations. Near the mouth of the Don, on the European side of the river, are a remarkable groupe of these tumuli, which from time immemorial have been known by the name of the *Five Brothers*. From their position and appearance, Dr Clarke supposes that they are the βωμοι, or altars either of Alexander or Cæsar, which were mentioned by Ptolemy in his *Geography*, lib. iii. c. 5. At a place called Zimlanskaia, on the Don, and about 200 miles above Tcherchaskoy, are said to exist the traces of a citadel built by Alexander the Great. The inhabitants have a tradition among them, that Alexander crossed the river at this place, and built a city or citadel. Dr Clarke saw two stelæ, or marble pillars, which had been brought from thence by General Orloff.

Government. Though the Don Cossacks are in complete subordination to the Russian government, they possess a constitution of their own, which is at once military and democratic, and which keeps them entirely distinct from the other subjects of the empire. Their territory is divided into 112 stanitzas, or cantons, which are disposed along the rivers in the following manner:

On the Don, including Tcherchaskoy, which contains eleven	62
On the Danaetz	9
On the Choper	20
On the Medveditz	11
On the Bouzoulook	10
Total	112

Each stanitza has a certain portion of land and fishery allotted to it by government, and an annual allowance of corn, according to the returned number of Cossacks. The distribution of the land among the inhabitants is settled by themselves with their Ataman; and every individual may either retain his proportion in his own possession, or let it out to farm. The Ataman, or Hetman, is both the civil and military commander of the place, and is annually chosen by the people. He used formerly, when the Cossacks were called upon actual service, to march at the head of his stanitza; but now he merely furnishes the required contingent of troops, which is put under officers named by the crown. The respect that is paid to him is entirely temporary, and only when he is engaged in the execution of his duty. If he convened any of the inhabitants upon business, however trivial, Dr Clarke observed that they made their obeisance before him, standing bare-headed, as in the presence of a sovereign; but the moment the assembly was dissolved, he passed unheeded among them, receiving no other mark of respect than any of the other Cossacks. These Atamans are all subject to the Glavnoi Ataman, who is generalissimo of the armies of the Don; and an appeal from their decisions lies to the Chancery at Tcherchaskoy, which consists of the Glavnoi Ataman as president, and the officers of the regiments as a council. The Glavnoi Ataman was formerly elected by the other Atamans, and his authority was almost absolute; but he is now appointed by the crown, and greatly diminished in power The Cossacks are exempted from all taxes, even from those of salt and distillation; and for the levies, which are required by their internal constitution, they impose small contributions on themselves.

Military state.

But for their allowance and privileges, they are liable to be called out on military service in any part of the world for a term not exceeding three years, mounted, clothed, and armed at their own expence. They must consequently be at all times completely ready to march, and when on actual service, they receive pay as other Russian soldiers, and are furnished by government with food and camp equipage. Those who have served three years, are generally freed from foreign service, except upon particular emergencies; and are employed chiefly in the cordon along the Caucasus, or in the duties of the post and police. After twenty years, their service are required only in the duties of the police, or in assisting the corn-boats over the shallows of the Don; and after twenty-five years service, they are entitled to complete exemption. Their officers were formerly without rank, and might be placed under a subaltern in the army, but they have now rank in the army; and their *polki* or regiments are put on a more regular footing, being uniformly clothed and accoutred. The military duty of the Don Cossacks, considering the state of the Russian peasantry, is well repaid by their privileges and the freedom which they enjoy; and "free as a Cossack," is a common proverb among their fellow subjects. War, indeed, is their greatest pleasure, for then they live according to their inclinations, and sometimes enrich themselves with the spoils of the enemy; and as they are more employed in service than the other corps of Cossacks, they are consequently better soldiers.

Appearance.

They are in general well made, handsome, and taller than the Russians. "There is something extremely martial," says Dr Clarke, "and even intimidating, in the first appearance of a Cossack. His dignified and majestic look; his elevated brows and dark mustachoes; his tall helmet of black wool, terminated by a crimson sack, with its plume, laced festoons, and white cockade; his upright posture; the ease and elegance of his gait, give him an air of great importance."—"Their dresses were much richer than any thing we had seen in Russia, although all were uniform. Each person's habit consisted of a blue jacket, edged with gold, and lined with silk, fastened by hooks across the chest. Beneath the jacket appeared a silk waistcoat, the lower part of which was concealed by the sash. Large and long trowsers, either of the same material as the jacket, or of white dimity, kept remarkably clean, were fastened high above the waist, and covered their boots. The sabre is not worn, except on horseback, on a journey, or in war. In its place is substituted, a switch or cane, with an ivory head: this every Cossack bears in his hand as an appendage of his dress; being at all times prepared to mount his horse at a moment's notice. Their cap or helmet is the most beautiful part of the costume; because it is becoming to every set of features. It adds considerably to their height; and gives, with the addition of whiskers, a military air to the most insignificant figure. They wear their hair short round the head, but not thin upon the crown. It is generally dark, thick, and quite straight. The cap is covered by a very soft and shining black wool. Some of them have civil and military distinctions of habit; wearing in time of peace, instead of the jacket, a long frock without buttons. The sash is sometimes yellow, green, or red, though generally black; and they wear large military gloves. There is no nation in the world more neat with regard to dress; and whether young or old, it seems to become them all."—"We never saw a Cossack in a dirty suit of clothes," he afterwards adds; "their hands, moreover, are always clean, their hair free from vermin, their teeth white, and their skin has a healthy and cleanly appearance." When on active service, every Cossask must keep two horses, one for himself and the other for carrying provisions, &c. Their arms consist of a lance about twelve feet in length, with an iron head, and a small streamer attached to it; a brace of pistols, with a cartouch box; a sabre, without either guard or cross bar, and a whip, which hangs from the right wrist; and which, being made of plaited leather as thick as one's thumb, they sometimes use against a conquered enemy, as well as for stimulating their horses. Their horses are small, but strong and active, and admirably trained. Their saddle is merely a wooden frame, with a leather cushion upon it, and under it is laid a piece of felt to save the horse's back. They ride short and full-footed, raising themselves in their stirrups, and bending their bodies with great activity; and never push their horses on full speed in a straight line, but when galloping wheel continually in a serpentine direction to the right and left. Each regiment has two or more banners of silk, on which are painted a patron saint, arms, &c. but they have no martial music. When not in action, the lance is slung on the foot or on the pummel of the saddle; but when

Accoutrements.

Cossacks. engaged, they put it under the arm, and direct it with great dexterity; when retreating, they rest it on the shoulder, opposing its point to the pursuing enemy. The Cossacks are well adapted for desultory warfare. They are very hardy, contented with scanty subsistence; and can take the field every day without intermission. They are encumbered neither with artillery, baggage, nor store-waggons. A piece of felt serves for their cloak, their tent, and their bed, and they feed their horses upon whatever they can find. They are seldom disciplined to attack in squadron, but act only as skirmishers, and are indefatigable in harassing the enemy. They particularly excel as patrols, are remarkable for their vigilance in outposts and their knowledge of the country; and from habit and practice they can discover the movements of the enemy far beyond the reach of usual observation, and by applying their ears to the ground, can distinguish the approach of an army at a very considerable distance. Indeed the Cossacks constitute the most useful and effective troops in the Russian armies; and, when let loose on a flying enemy, are most destructive. In the Austrian campaign of 1805, seventy-two regiments of 560 men each, under General Platof the Ataman of Tcherchaskoy, were ordered to join the armies, but they arrived too late for the battle of Austerlitz. There were present in that battle 600 Cossacks, who suffered dreadfully, as they were for some time the only cavalry with the Russian army; and, before the Emperor joined Kutusof, had lost almost all their horses with fatigue. In the campaign of last year (1812), however, they have been more successful, and greatly contributed to the destruction of the French army. See RUSSIA.

Women. The Cossack women are in general beautiful, but rather singular in their dress. Matrons wear an immense cap, resembling the mitre of a Greek bishop, bespangled with jewels, or covered with flowers, with the hair tucked under it; but girls have merely an Indian handkerchief wrapped round the head, with their hair plaited and hanging down the back. They all wear trowsers which reach to the ancles, and over them a silk or cotton tunic. In their domestic employment they go barefooted, but when in full dress they have slippers and stockings of yellow morocco. White linen is scarcely used, except among the poor, the shifts of the rich being commonly made of dyed cotton or Asiatic silkstuffs, either of a yellow or blue colour. Other parts of their dress that are seen, are generally of muslin.

Manners and customs. The Cossacks have been long considered by the other inhabitants of Europe as semi-barbarians, both in their manners and dispositions; and, indeed, they are still represented in that light by the Russians, who, envious of their privileges, attempt by every means to vilify and degrade them to strangers. Professor Pallas has even imbibed much of the Russian prejudice with regard to this people, and has given a very melancholy picture of the state of society in their capital. Mr Tooke also describes their countenance and character as entirely Russian, but rendered, by their education and course of life, only more bold and resolute than the Russian vulgar. Dr Clarke, however, has completely removed these aspersions, and has established their character as very superior indeed to any of the natives by whom they are surrounded. In his progress through their country, he met with the greatest attention and politeness. He travelled with greater security, and was less exposed to impositions and insult than ever he had experienced among the Russians. At the first stanitza which he visited, the Ataman gave up his own house entirely to his use, which was well stocked with provisions and luxuries of every kind; and when he offered some remuneration for the accommodation which he had received, he was told that "Cossacks do not sell their hospitality." He every where found a brave, lively, and hospitable people, was pleased with their appearance, and admired their independence. "Polished in their manners, instructed in their minds, hospitable, generous, disinterested, humane and tender to the poor, good husbands, good fathers, good wives, good mothers, virtuous daughters, valiant and dutiful sons; such," says he, "are the natives of Tcherchaskoy.* In conversation the Cossack is a gentleman; for he is well-informed, free from prejudice, open, sincere, and honourable."—"The manners of the people," says Mr Heber, "struck us, from their superiority to the Russians, in honesty and dignity. A lieutenant at Petersburgh, once begged alms from us, bowed himself to the ground, and knocked his head on the floor. A lieutenant here, (Tcherchaskoy), who was imprisoned, and also begged, made the request in a manly and dignified manner, and thanked us as if we had been his comrades. They are, however, indolent, and fond of pleasure; violent when irritated, and vehement in their amusements. Some of them live in great affluence, and enjoy the refinements and luxuries of the most polished and civilized nations. The custom of drinking toasts, and of rising to pledge the security of the cup-bearer, as also the more ancient one of bowing and congratulating any one who happens to sneeze, are very prevalent among this people; and though the poorer classes have plenty of excellent food, and as much brandy as they can drink, yet the greatest order and harmony are maintained in their stanitzas. In Tcherchaskoy, the inhabitants are very gay and social. They have frequent balls and parties of pleasure; and they had once a theatre, but it is now prohibited. The Cossack dance resembles very much the English hornpipe, but it is accompanied by whistling, and by short and sudden shrieks. They move the head from one shoulder to the other, while the

* Professor Pallas, who spent only one day at Tcherchaskoy, has given us a very different account of its inhabitants. "I cannot speak favourably," says he, "of the moral character of its inhabitants, whether male or female. A continual habit of good living, indolence, and debauchery, the natural consequences of the superfluity which the excellent possessions of this free militia afford, have thoroughly corrupted their manners, and their ancient simplicity has been almost entirely superseded by luxury. Here, as in other countries, the capital is the seat of corruption, which gradually infects the mass of the people The distinctions and privileges, which have in later times been too liberally granted to the higher ranks, have rendered these, as well as the people, proud and insolent. The former, who have established villages on the beautiful tracts of land granted to them on the eastern bank of the Don, and encouraged vagrants to settle there, endeavour to oppress the poorer class of inhabitants, by imposing upon them all the burthens of military duty; though they spare the more wealthy, whose common interest it is to deprive the latter frequently even of the payments due for their services. The discontent resulting from this conduct is construed by their superiors, into want of obedience and mutiny, so that it is productive of additional oppression. Thus a people naturally well disposed, and who have hitherto been very useful to Russia in furnishing the empire with light troops, are continually more injured in their free constitution, and daily shew greater aversion to military service; while their affluent governors live in the most voluptuous indolence and immorality." Pallas *Trav.* vol. i. p. 469.

Cossacks. hands are held up near the ears. This attitude, which, with the sudden shrieks, prevail very much among the lower orders of Scotland, is common to the dances of all the Tartars and Chinese. The Highland bag-pipe is much in use in this country, and is often accompanied by Calabrian puppets, which are so managed by the pipes as to move in time with the music. The Cossacks have a kind of solemn games, which consist entirely in martial exercises, such as riding, tilting, and hacking with the sabre. Upon such occasions, they are ambitious of shewing their dexterity, and always appear well mounted, and in their best attire. The arrival of the ammunition, which is annually sent hither by the crown, is always considered by them as a kind of festival day. It is met by all the stanitzas in parade, and received at Tcherchaskoy by the regiment of the place, with colours flying, and brought in grand procession to the arsenal.

Religion. The Cossacks are generally of the Greek religion, but neither so ignorant nor illiterate as they have been often represented, and their clergy are under the jurisdiction of the bishop of Woronetz. A ceremony, called "The Benediction of Bread," takes place in all their churches every Saturday evening. Five white loaves, symbols of those with which our Saviour fed the multitude, are placed in the middle of the church; and all the people pray that, "as with five loaves he fed the five thousand, he would vouchsafe a sufficiency of corn in the country for the bread of its inhabitants, and bless it for their use."

Mr Tooke represents them as totally negligent of all science and letters, but entirely addicted to war, having rendered themselves famous only as heroes and conquerors, and sometimes as rebels or tyrants—Yermak the conqueror of Siberia, and the impostor Pugatshef being both Cossacks of the Don. But though none of this nation have ever appeared among the literati of Europe, yet they are not to be considered on that account as destitute either of literary knowledge or abilities. In Tcherchaskoy there is a public academy, where are taught various languages, geometry, mechanics, physics, geography, history, arithmetic, &c. and where all the children of the officers are educated. Dr Clarke has paid a very high tribute to their literature and accomplishments in his character of Lieutenant-Colonel Papof. "To this officer," says he, "we were indebted for instances of hospitality and polite attention, such as strangers might rarely expect in more enlightened cities of Europe. His education had been liberal, although received in the marshes of the Don; and his accomplishments might have graced the most refined society, although derived from the natives of Tcherchaskoy."

Commerce. The commerce of the Cossacks is not considerable, being carried on chiefly with the Greeks and the inhabitants of Kuban, and consists in grain, iron, timber, sail-cloth, hemp, fish, caviare, horses, horned cattle, tallow, and butter. Their capital, Tcherchaskoy, however, was formerly a place of great commercial importance, where the productions of Russia and Turkey were reciprocally exchanged. It was also the emporium of an inland commerce between the merchants of Kuban and Crim Tartary, and the Russians. Its imports were chiefly Greek wines, raisins, dried figs, almonds, oil, rice, saffron, painted linens, and cottons; and its exports were hides and leather, coarse linen, hard-ware, caviare, &c. Plenty of timber is brought from the forests, which cover the banks of the Don and the rivulets which fall into it, and is floated down the stream to St Demetri and Rostof. The shops in the principal towns are generally well supplied with most articles of luxury, and nothing is wanting that can contribute to the comforts and conveniences of a civilized people.

Principal towns. The principal towns in the Don Cossack territory are Tcherchaskoy and Kasankaia, both upon the Don, and both of considerable size. The former contains about three thousand houses, and fifteen thousand inhabitants. Its buildings are chiefly of wood, and all raised from the ground on wooden piles; for when the river is flooded by the melting of the snows, the whole town, except a few principal places adjoining the cathedral, is so inundated, that many of the ground floors of the houses are completely under water. It formerly had walls, but they were swept entirely away; and during the inundations, the only communication which the inhabitants have with each other is by means of bridges or boats. The stanitzas, in general, have the appearance of badly fortified villages, and their population is very unequal. Each of them, however, has a church, some of them two, a court-house, an ataman, and other officers, with a few pieces of cannon. The churches are every where good, and indeed much superior to what we find in the villages of our own country, both as to architecture and interior decorations. The houses are mostly of wood, and are so constructed, that they may be removed entire from one place to another. They are much cleaner, and better furnished than those of the Russians; many of their rooms are handsomely fitted up with paper hangings, and ornamented with no mean paintings of saints, virgins, and bishops.

Population. The population of this territory has never been exactly ascertained, as the Cossacks will allow no examination into their numbers. It is conjectured, however, that there are about 200,000 Cossack inhabitants, of whom 25,000 are in arms; and they can at any time furnish above 50,000 cavalry completely equipped. There are also in this country 30,000 wandering Calmucks scattered over the *steppes*; and of these 5,000 bear arms, and are ready at all times for actual service.

The other denominations of Cossacks, besides those of the Don, are, the Malo-Russian Cossacks, the Tchernomorski, or Cossacks of the Black Sea, the Cossacks of the Volga, of Grebenskoy, of Orenbourg, of the Ural, and of Siberia, with other smaller branches.

Malo-Russian Cossacks. The Malo-Russian Cossacks had their origin much later than those of the Don; and, it would seem, assumed the name of Cossacks, or had it bestowed upon them merely from the nature of their government. They are supposed to have at first consisted of a multitude of fugitives from Poland and Russia, who, having settled in the lower regions of the Dnieper, which they called Malo, or Little Russia, adopted a military form of government, in order the better to maintain their independence. By degrees they spread themselves towards the south over the whole country, between the Dnieper and the Dniester; and were almost continually engaged in petty wars with the Tartars and Turks. They had even penetrated into the Crimea, captured Trebisond, and made military campaigns to Constantinople. They thus formed a barrier to the king of Poland on the side of Turkey, and their republic on that account was encouraged and protected by the Polish sovereigns, whose supremacy it acknowledged. But this protec-

Cossacks.

tion at last degenerated into oppression; and was followed by a rebellion of the Cossacks, who, after a tedious war, threw off their allegiance to Poland, and formally submitted themselves to the Tzar of Russia in 1654, about three hundred years after their first institution as a distinct government. Since that time, however, the form of their government has been greatly changed, and they now scarcely retain any vestiges of their ancient freedom. They are very numerous, but great numbers of them are registered only as Reserve Cossacks; and 30,000 only are kept in constant service and pay, and wear the hussar uniform and arms. From their manners and way of life, however, the Malo-Russians are still considered as a distinct people. In their features, in their amusements, in their love of mirth and drinking, and in the dress of their females, they resemble the Don Cossacks; but they are far superior to them in industry. They have converted many of their desolate steppes into rich fields of corn; and they rear an immense number of fat cattle, which are sent to Breslau, Petersburgh, &c. The overplus of their grain they partly export, and partly distil into brandy, of which they have always a prodigious quantity, both for sale and for their own consumption. "They are a more noble race," says Dr Clarke, "stouter, and better looking than the Russians, and superior to them in every thing that can exalt one class of men above another. They are cleaner, more industrious, more honest, more generous, more polite, more courageous, more hospitable, more truly pious, and, of course, less superstitious."

Cossacks of the Black Sea.

The TCHERNOMORSKI, or *Cossacks of the Black Sea*, inhabit the peninsula of Taman, and the country between the Kuban and the sea of Azof, as far as the rivers Ae and Laba, comprehending an extent of territory of above a thousand square miles. They are a branch of the Malo-Russian Cossacks, and their history is rather curious. Their original appellation was Zaporogztsi, from the place of their former residence, implying *beyond the cataracts* of the Dnieper; and they at first consisted only of a band of martial Malo-Russian youths, who were placed on the southern borders of that river, as a frontier defence against the inroads of the Tartars. Being all unmarried, and pleased with the freedom which they enjoyed, they continued in their dangerous posts, and were never desirous of being recalled. War and plunder were their habitual employment; and they were soon joined by others, who either wished to engage in military exercises, or sought a shelter among them from Polish oppression. Their numbers thus gradually increased, and at last became so considerable, that about the beginning of the seventeenth century, they separated from the parental stock, and erected a military state of their own. Their constitution was purely democratic. All were equally eligible to the sovereign dignity of Ataman, who was annually chosen by a plurality of voices, and who, upon the expiration of his office, was again numbered among the common Cossacks, and received no greater respect than the rest of his brethren. Their *setscha*, or chief residence, was at first situated on an island of the Dnieper, below the cataracts; but it was afterwards occasionally removed from one place to another. It consisted of a collection of huts, surrounded by a wooden fortification, and had a kind of fortress, which contained their artillery, arms, ammunition, and warlike stores. It was divided into 38 quarters, each of which had an ataman and other officers, who were, however, all subject to the chief ataman. In the market-place were exposed to sale provisions, clothes, and all kinds of necessaries, which were brought hither by foreign merchants, who took up their quarters in the suburbs. No women were admitted into the *setscha* upon any account whatever, and celibacy was most strictly enjoined upon every member of their society. But in order to keep up their numbers, they carried off children wherever they could find them; and welcomed and adopted fugitives from every nation, who were willing to conform themselves to their discipline and regulations. None were detained contrary to their inclinations. Every individual was at full liberty to depart when he pleased; and to be a Cossack was, in their opinion, too great an honour, to be forcibly conferred upon any one who was dissatisfied with their government, or way of life. The greater number of them lived in the setscha, but many of them dwelt also in a suburb adjoining it, or inhabited the small villages that were situated within their territories; and, in order to gratify the instincts of nature, they frequently carried off women from the Tartars and Poles, or got loose females from Little Russia, with whom they lived without any forms of marriage, but were obliged to keep them at a distance from the setscha. Though they subsisted almost entirely by rapine, yet, in proportion as bounds were set to their depredations, many of them engaged in traffic and the common trades, and others employed themselves in agriculture or graziery. But whatever were their occupations, nothing was allowed to prevent them from fulfilling the regulations of the setscha. These Cossacks were all of the Greek church; and the first fruits of their robbery were generally given to the church and its ministers. With the rest they bought handsome arms and clothes, or spent it in drinking, and in treating their comrades; and though they were active and temperate on their expeditions, they were lazy and gluttonous when at home. The Zaporogztsi could at times muster about 40,000 effective men. They were nominally under the sovereignty of Russia, and their bravery was often most successfully displayed in the campaigns of that power with the Tartars and Turks. Their services, however, were not always to be depended upon, as they sometimes changed sides when it suited their own interests or inclinations. One while they were with Poland, at another time with Russia, and even at times sided with the Tartars or the Porte. Peter the Great destroyed their setscha for joining in the rebellion of the Ukrainian Ataman Mazeppa; but they afterwards assembled under the protection of the Khan of the Crimea, and in 1737 were again admitted as Russian vassals. They still, however, lived in the same manner, and though formidable to their enemies, they were almost equally dreaded by their allies. They plundered the Russian merchants who passed through their territories, and interrupted, by continual piracies, the navigation of the Dnieper. These outrages, with their almost total neglect of agriculture in so fertile a country, and their constant resistance to every reformation in their government, determined the Empress Catherine II. to dissolve their confederacy; and in 1774 their setscha, which then stood at the junction of the Bouzoulook and the Dnieper, was surrounded, and destroyed by General Balmain, their arms were taken from them, and by an imperial manifesto they were allowed either to settle as

Cossacks of the Black Sea.

quiet and useful subjects, or to withdraw from the empire. Some of them took to agriculture and various trades, while others went over to the Tartars, or led a wandering life about the Russian frontiers. Many of them, however, afterwards returned and applied for military service; and as a reward for their zeal and bravery in the second Turkish war, the Empress, by an ukase of the 30th of June 1792, ceded to them their present residence, which was then newly conquered from the Kuban Tartars. They enjoy nearly the same privileges as the Don Cossacks. They have the full property of the soil, fisheries, and salt-marshes, and the right of distilling spirits. They also elect their own Atamans, but are immediately dependent on the governor of Taurida. They are, however, much poorer and more uncivilized than the Cossacks of the Don, and seldom quit their country, as they have sufficient employment at home in repressing the inroads of the Circassians. The Tchernomorski, according to Dr Clarke, bear no resemblance whatever to the Don Cossacks, either in habit, disposition, or in any other characteristic. "The Cossacks of the Don all wear the same uniform; those of the Black Sea any habit suiting their caprice. The Don Cossack is mild, affable, and polite; the Black Sea Cossack is blunt and even rude, from the boldness and martial hardihood of his manner. If poor, he appears clad like a primeval shepherd, or the wildest mountaineer; at the same time having his head bald, except one long braided lock from the crown, which is tucked behind the right ear. If rich, he is very lavish in costliness of dress, being covered with gold, silver, velvet, and the richest silks and cloths of every variety of colour; wearing at the same time short cropped hair, giving to his head the appearance of the finest busts of the ancient Romans."—"They are more cheerful and noisy than the Don Cossacks; turbulent in their mirth; vehement in conversation; somewhat querulous; and if not engaged in dispute, are generally laughing or singing." The braided lock on the crown of the head is the characteristic mark of the Tchernomorski, and distinguishes them from every other tribe of Cossacks in the Russian empire. It is preserved with religious veneration, and they would lose their life rather than part with it. This people are most dextrous horsemen, and when mounted have a noble and martial appearance. Their officers in general wear red boots, which is their principal distinction, and are otherwise very gaudily dressed; and still retain their ancient valour and love of war. They are held in little estimation by their neighbours on the Don, and are considered rather as an inferior band of plunderers, but without any sufficient reason. They are hospitable to the best of their means; and the following fact bears remarkable testimony to their honesty. When Mr Heber was travelling in this country, his companion Mr Thornton lost his gun, and supposing it to have been stolen, they left Ekaterinedara without the least hope of ever seeing it again. To their great surprise, however, when they arrived at Taman, the gun was brought to them, and notwithstanding the length of the journey, being above 200 English miles, the person who was employed to restore it to its owner refused to accept any reward for his labour.

The soil throughout the territory of the Tchernomorski is, in general, rich, but very little of it is in cultivation. They rear some cattle, and also most kinds of grain, as wheat, barley, oats, millet, rye, and maize. The climate, however, is in many places very unhealthy, and a great number of the inhabitants are annually swept away by malignant fevers. The commerce which they carry on with the Circassians consists chiefly in salt, for which they receive in exchange wood, honey, corn, mats, and arms. Their principal settlements are Taman, Temrook, Atshuef, and Ekaterinedara, or Catherine's Gift. This last is their capital, and the residence of their Ataman, and council of war. It has a very extraordinary appearance, consisting merely of a number of straggling cottages situated in the midst of a forest of oaks. The cottages, however, are remarkably neat, with a large area before the door, and an avenue of stately oaks; and their gardens are well stocked with vines, cucumbers, wall-melons, &c. The number of the Tchernomorski, including both sexes, amounts to about 20,000, among whom are 15,000 troops well disciplined and equipped. Of these a thousand are stationed along the lines to watch the motions of the restless Circassians; as many are kept as a body of reserve in and near the capital; and about a thousand are employed in the flotilla which lies in the Bugas. They have above a hundred pieces of cannon of different calibres, some of which are on board the flotilla; and the rest at various posts.

Cossacks of the Volga.

The Cossacks of the Volga, as well as all the other tribes of Cossacks towards the east, are a branch of the Don Cossacks. They at first only passed their summers on the Volga, and returned in winter to their stanitzas on the Don; but at last becoming stationary on the former river, they were declared independent of the parent stock in 1734. A few of them, however, only retain their Cossack constitution; the rest being placed under the usual municipal magistracy, as merchants, burghers, or boors, and consist of two regiments, the *Dubofskoy* and *Astrachanskoy*, which are kept in constant pay. The Dubofskoy are registered at about 1000 men fit for service, though they could easily triple that number. The Astrachanskoy are equally numerous, and are almost all in arms.

Grebenskoy Cossacks.

The Grebenskoy Cossacks, consisting of 1200 effective men in constant pay, are stationed in five fortified stanitzas along the Zerek, as a defence against the highland Tartars of Caucasus.

Orenbourg Cossacks.

The Orenbourg Cossacks inhabit the stanitzas along the Samara, and the upper parts of the Ural from the Ilek; and are employed in repelling the attacks, or in punishing the depredations of the Kirghises and Bashkirs. They could easily bring 20,000 men into the field, but only from 8000 to 10,000 are enrolled for military service.

Cossacks of the Ural.

The Cossacks of the Ural,* according to their tradition, first separated from the parent stock about the beginning of the fifteenth century, and established themselves at the mouth of the river Ural. They afterwards obtained a regular constitution from the Russian government, with the same privileges as the Cossacks of the Don. They now extend along the Ural from the Ilek to the Caspian, and perform service against the Kirghises. They live chiefly by fishing, and the breeding of cattle; and their number is computed at 30,000 men fit to bear arms, of whom a corps of 12,000 are always kept properly equipped.

Siberian Cossacks.

The Siberian Cossacks had their origin in a predatory expedition of a horde of Don Cossacks, who pro-

* They were formerly called the Cossacks of the Yaik, but having joined in the rebellion of Pugatchef in 1773, the Russian government, in order to efface the remembrance of it, changed their name, with that of the rivers and their capital, to those which they now bear.

ceeding eastward plundered and laid waste the Russian territories on the Volga; and embarking on the Caspian, made themselves formidable by their piracies to all the surrounding nations. The Tzar Ivan II. enraged at their depredations, assembled a considerable army to punish their audacity, which so terrified the robbers that they soon dispersed and fled into the neighbouring regions. A body of about 7000, however, still kept together under their Ataman Yermak, and advancing along the river Kama towards Permia ascended the Ural mountains. Immense wildernesses, and ferocious tribes before unknown to Europeans, now presented themselves, and would have stopt the progress of a less adventurous spirit than that of Yermak. But animated with the idea of founding a new and extensive empire, he descended eastward with his resolute companions, defeated the Tartar Khan, and passed the Tobol, the Irtish, and the Oby, subjugating in his victorious career the Tartars, Vogules, and Ostiaks. His little army, however, was soon diminished by battles and fatigue; and unable, with such scanty means, to accomplish his object by the establishment of a new kingdom, or to keep in obedience so many conquered nations, made over his conquests in 1581, to the Tzar Ivan, who nobly rewarded him for his magnanimity. But Yermak did not long enjoy his good fortune. He died about four years after. The discoveries and conquests, however, which he had so successfully begun were vigorously prosecuted by the Emperor, who sent thither reinforcements of Don Cossacks for that purpose, and who soon saw his dominions extend to the eastern ocean and the mountains of China. The Cossacks remained in the country as a militia, and many of them married with the natives. Their present number is said to exceed 100,000, but of those only 14,000 do military duty, the rest are engaged in various trades. See SIBERIA.

The whole number of the Cossack male population in the Russian dominions is reckoned at half a million; and of these about 200,000 are liable to be called on for government service of one description or other. See Clarke's *Travels,* vol. i. p. 227, &c.; Pallas' *Travels in Russia,* vol. i. p. 468, and vol. ii. p. 330; Tooke's *View of the Russian Empire,* vol. i. p. 390; Coxe's *Travels,* vol. ii. p. 275; Plescheef's *Survey of the Russian Empire,* p. 318; Chantreaux's *Travels,* vol. ii.; Hanway's *Travels,* vol. i. p. 97; Storch *Tableau de l'Empire de Russie,* vol. i. p. 25; and Campenhausen's *Travels,* p. 34, in Philips's Collection, vol. viii. (*p*)

COSSAE is a term applied to a species of cotton cloth, like most others originally imported from India, and differs so very little from calico in almost any particular, as to require very little description to those who have read that article. The cossae is generally finer than the calico, and like it, is chiefly used for the purpose of printing. It is rather lighter in the fabric, forming a kind of intermediate texture between that and the jacconott. They are most commonly woven in 1000, 1100, or 1200 reeds of the Scottish measure, or from 32 to 40 of the Lancashire measure. The breadth is generally given out by those who expose them to sale, as $\frac{7}{8}$ths of a yard, which is equivalent to $33\frac{1}{2}$ inches; but from the prevalent practice of rendering goods *apparently* cheap by deterioration of quality in almost every particular, they very frequently do not exceed 28 or 29 inches of actual measure. About No. 44 or 46 may be considered as nearly the average number of warp allotted to an 1100 reed. When it is found difficult to procure weavers to undertake these narrow goods, which is always the case when work is plentiful, the manufacturers are obliged to have them woven double the breadth, and to leave two intervals of the reed vacant in the middle to mark the division. These are afterwards cut asunder into two separate webs; and as one side of each piece will be deficient in what is termed the selvage, this deficiency is afterwards supplied by a slight sewing with the common needle. Although these goods are in general rather superior in point of quality to the narrow ones, from being generally better woven than the others, which must often be entrusted to unexperienced boys, a very general prejudice prevails against them; and the merchant always complains, that while a piece of the narrow goods with the double selvage remains on hand, he cannot dispose of them. Whether this arises from a jealousy, that the one side has been damaged and cut off, it is impossible to say, but the fact is certain. When cossae muslins are well fabricated and printed, they form an elegant and showy part of female attire, at a very cheap price, that of the cloth before printing seldom exceeding in wholesale quantities one shilling per yard. From this circumstance they are very saleable; and when the general muslin trade is even tolerably good, it is hardly possible to procure a sufficient number of weavers to supply nearly the demand. Capitalists, therefore, frequently take the advantage of occasional stagnations of the other branches to stock themselves largely at cheap rates. (J. D.)

COSSIGNEA, a genus of plants of the class Hexandria, and order Monogynia. See BOTANY, p. 183.

COSTUS, a genus of plants of the class Monandria, and order Monogynia. See BOTANY, p. 82.

COTE-D'OR, the name of one of the departments of France, formed out of part of Burgundy. It is bounded on the north by the department of the Aube, on the north-east by that of the Upper Maine, on the south-east by those of the Upper Saone and the Jura, on the south by that of the Saone and Loire, and on the west by those of the Nievre and the Yonne.

The soil of this department is in general bad, and is impoverished with weeds; but the rich plains in the district of Dijon produce plentiful crops of corn and hay. The principal products of the department are wine and iron. The famous Burgundy wine is produced from the chain of hills called the *Golden Coast,* on account of the profit which is drawn from this source. In the year 1806, no fewer than 322,842 pipes were made in the department.

The extent of the Cote-d'Or is 876,956 hectares, of which 207,600 are covered with forests. The annual contribution in taxes is 3,905,657 livres, and the population is 347,842 souls. The principal rivers are the Seine, the Saone, the Ouche, the Tille, &c. and the chief towns are Dijon, Chatillon, Semur, Beaune, Auxonne, and Nuits. (*w*)

COTES, ROGER, a celebrated mathematician, was born at Burbage in Leicestershire, on the 10th of July 1682, and was the son of the Rev. Robert Cotes, who was rector of that place. At the early age of eleven years, when he was receiving his education at the school of Leicester, he exhibited an ardent passion for geometry, which was fostered by his uncle Dr John Smith, who took young Cotes under his own roof, and anxiously superintended his mathematical studies. After having acquired at Leicester the elements both of classical and mathematical learning, he was sent to St Paul's school in London, where he made rapid progress in classical at-

Cotes.

tainments, without neglecting his favourite pursuits. In the month of April 1699, before he had completed his 17th year, he was admitted pensioner of Trinity College, Cambridge, and after having been appointed private tutor to the Earl of Harold, he was elected fellow of Trinity College in 1705. In January 1706, in the 24th year of his age, Cotes was unanimously appointed Plumian professor of astronomy and experimental philosophy, an office which he discharged with peculiar credit. In the same year, he took his degree of Master of Arts; and, in 1713, he entered into holy orders. The fame which Cotes had now obtained, was greatly increased by a new edition of Sir Isaac Newton's *Principia*, which he published at the desire of Dr Bentley, and which he enriched with an admirable preface; but he did not live long enough to extend his reputation, or to enjoy that portion of celebrity which he had already acquired. He was cut off in the prime of life, and in the vigour of his mind, on the 5th of June 1716, in the 33d year of his age. His remains were deposited in the chapel of Trinity College, and his friend Dr Bentley wrote a Latin inscription to his memory.

The only works which Mr Cotes published during his life, were his edition of the *Principia*, and a description of the Meteor of the 6th March 1715-16, which was printed in the Philosophical Transactions. The works which he left behind him, were, 1. the *Harmonia Mensurarum, sive Analysis et Synthesis per rationum angulorum mensuras promotæ*, which was edited and enlarged by his relation Dr Robert Smith. 2. *Hydrostatical and Pneumatical Lectures*, a work which he refused to publish during his life.

The reputation of Mr Cotes is founded chiefly upon the elegant geometrical theorem, now universally known by the name of the *Cotesian theorem*, which was found among his papers without any demonstration, and of which we have given a full account in our article on the ARITHMETIC *of Sines*, (Vol. II. p. 438, 439). He had the high satisfaction of enjoying the esteem of Sir Isaac Newton, who particularly lamented his premature death, and remarked, that had "Cotes lived, he would have done something for science." See Dr Pemberton's *Epist. de Cotesii inventis*, and De Moivre's *Miscellanea Analytica*. (*w*)

COTES DU NORD, the name of one of the departments of France, formed out of Upper Brittany. It is bounded by the British Channel on the north, from which circumstance it derives its name; by the department of Ille and Villaine on the east; by that of Morbihan on the south; and on the west by that of Finisterre.

This department contains extensive tracts of heath; but the arable land is very fertile, and produces corn, hemp, and flax. The pastures are extremely good, and the orchards, which are numerous, abound in apples, of which considerable quantities of cyder are made. Iron and lead likewise occur.

The extent of this department is 736,720 hectares, of which 23,876 are covered with forests. The annual contribution in taxes was 2,549,791 livres, and the population is 499,927 souls. The principal rivers are the Guet, the Treguier, the Argueron, the Ranxe, the Lie, the Oust, and the Blavet. The chief towns are St Brieuc, Loudeac, Dinan, Guingamp, Lanion, and Plestin. (*w*)

COTTON.

Cotton.

COTTON is a name, which, in common language, is very loosely given to any vegetable filamentous substance; but it is correctly appropriated to that peculiar vegetable matter, consisting of innumerable fine filaments, arranged together within an external coat, and enveloping the seeds of the genus Gossypium. This genus is found in both the Indies, in Africa, and in the warmer parts of Europe; but its cultivation to any extent is, in a great measure, confined to the East and West Indies. This genus belongs to the class Monadelphia, order Polyandria, (see BOTANY,) and possesses the following characters: Calyx double; exteriorly 3 cleft. Capsule quadrilocular. Seeds involved in cotton. Botanists enumerate ten species of Gossypium, the characteristic distinctions of which are to be found in the form of the leaf, and in the size of the tree. Willdenow has given the following species:

1. Gossypium Herbaceum.
2. . . . . Indicum.
3. . . . . Micranthum.
4. . . . . Arboreum.
5. . . . . Vitifolium.
6. . . . . Hirsutum.
7. . . . . Religiosum.
8. . . . . Latifolium.
9. . . . . Barbadense.
10. . . . . Peruvianum.

If, however, the observations of M. Lasteyrie be correct, the number of species should be considerably augmented; but that writer has betrayed such gross ignorance, and so strong a disposition to mis-statement with regard to facts, of which we have means of judging, that we should not adopt any opinion advanced by him without the sanction of some respectable authority. Only a few of the species are cultivated by Europeans. The mode of cultivation differs but in the general detail. We shall point out as accurately as we can, the prevailing modes, as well as any remarkable differences, so as to convey pretty accurate general ideas of the subject. The mode of cultivation depends on the plant being annual or perennial. The general preparation of the soil must be influenced by the climate, and other incidental circumstances that cannot be properly detailed in this place. In general, the annual cotton tree thrives best in a dry gravelly soil. It is also said to answer better in old than in newly cultivated land. An exposure to the east, where the country is hilly, is considered by some to be of importance. The culture begins in March and April during the rainy weather. Holes are then made in rows at the distance of from seven to eight feet; into each of these an indefinite quantity of cotton seed is put: in a short time they germinate; and as soon as the young plants rise to a height of six or seven inches, all, excepting two or three of the most vigorous, are pulled up by the roots. The surviving plants are pruned twice before the month of August, so as to keep them down to the height of about four feet. This is absolutely necessary, as when there is a great abundance, the difficulty of gathering the cotton is increased without any addition to the quantity. Great care is required to free the plantations from weeds. Light showery weather is the most favourable to the plentifulness of the crop.

Mode of cultivation.

In some parts, particularly on the coasts of Guiana and the Brazils, the perennial cotton tree is almost exclusively cultivated. Of this we are enabled to give a very accurate account, which we have derived from an acute and intelligent planter in the colony of Demerary, where the cultivation of cotton has been carried to a high pitch of perfection. On the coast of Guiana the land is all alluvial mud, thrown out of the great rivers that empty themselves into the ocean in its immediate neighbourhood. Land is daily formed by the same causes. The elevation above the level of the sea is so inconsiderable as to render inundations not uncommon, and the whole country is intersected by ditches, without which no cultivation could be carried on. This peculiarity of the country is to be considered, whatever is the object of cultivation; but there are some particulars that are to be exclusively attended to by the cotton planter. The land in which cotton is to be planted must be formed into beds of about 36 feet wide, which are to be surrounded by drains that run across the estate, and empty themselves into the trenches that run parallel with the length of the estate. These beds should be slightly elevated towards the middle by means of the soil dug out of the drains, so as to throw off the superabundant water more readily than if they were perfectly horizontal. This is peculiarly necessary, as any stagnation of the water around the root of the tree is very injurious to it in every stage of its growth. When the land has been thus prepared, it is divided into squares of from three to six feet, according to its nature, but the average is about five feet. Some indeed do not divide the surface into squares, but into parallelograms of five feet by four. The squares are marked out by a line prepared for that purpose, or by pickets stuck into the ground, in which small holes, four or five inches deep, and six or eight wide, are dug with a hoe, a little light earth is then scraped into the hole, and a small handful of seed laid upon it; the whole is then lightly covered with earth. If the weather be showery, (which it ought to be when cotton is planted,) the seed will spring up in three or four days. When the plants are three or four inches high, they ought to be pulled by the hand, leaving three or four in each hole. This is generally done within a month after the first planting. About the same time the ground generally requires a first weeding, which must be repeated every month, until the trees are fully grown. At the second or third weeding, one tree only is left in each hole, and then if it be eighteen inches, or two feet high, the tops are nipped off to make the tree throw out a sufficient number of lateral shoots. The usual period of planting cotton in Dutch Guiana is during the months of December, January, April and May. If in the two first months, which are preferable, the tree will require to be pruned in June, to prevent its becoming too high. This is done about three feet above the ground, at the same time all the shoots from the stem above one foot from the ground are pulled off. But if the cotton be planted in April and May, the branches will only require to be nipped about twice with the finger, and the plant will generally yield some cotton before Christmas, indeed from the month of October if the weather be dry. In general, however, the cotton tree rarely produces a full crop before it has attained its second year, and its duration is generally estimated at four or five years. The replanting is not done in any regular way, but whenever a tree fails another is planted in its place, which is called supplying a field of cotton. This is particularly attended to at the period of weeding. The cotton trees that are a year old are regularly pruned once a year, between the months of April and July. The time of beginning depends in a great measure on the weather, and the prospect of the trees yielding any more.

In regular seasons, the crop in Guiana is generally finished in April, and if the season be mild, May is the fittest month for pruning, which generally employs the gang for about a month. The fields must be previously weeded, care being taken to cut out all the old or rotten branches, to regulate the distance of these branches, as well as the height of the tree, which should be about four feet. This last circumstance must depend in a considerable degree on the nature of the soil. After the pruning, the utmost attention should be paid to keeping the ground free from grass and weeds, which grow very rapidly at that season. To produce the desired effect, the fields should be weeded thrice between the pruning and the gathering in of the crop. This must be regulated by the number of people on the estate. The cotton, if the season be favourable, begins to throw out abundance of blossom by the end of July, or the beginning of August; the pods form in succession, and generally begin to open in about six weeks: it rarely happens that there is any general picking before the end of October, and it continues till about the end of December, making what is called the first crop. The short rainy season then begins, and during its continuance the trees vegetate with uncommon vigour, and blossom. The second crop, when the weather is mild, should commence by the end of February, and continue to the middle of April. To ensure the vigour of the trees, the fields should be weeded between the first and the second crop; if possible, immediately on the close of the first. Little confidence can, however, be placed in the expectation of a second crop, from the prevalence in Guiana of cold northerly winds, accompanied with much rain from December to April. These always injure, and generally destroy, the crop, either by making the blossoms and young pods drop from the trees, or if the latter arrive at maturity, by making the seed and cotton stick to each other instead of bursting freely. The disease thus induced is called the blast; and we shall give a more particular account of it hereafter.

In the West India islands, and in Georgia, the same mode of cultivation is pursued. The cotton trees, however, must be annually planted, owing to some local peculiarities.

In Guiana the pure blue clay is considered the best for this species of growth, particularly that which is daily forming along the shores of that part of South America. From this fact, it has been inferred, that salt promotes the growth of the cotton tree; and, in conformity with that opinion, the old lands are frequently inundated with salt water, and we believe with very considerable benefit. Other soils, such, for instance, as are sandy and gravelly, are equally productive with the clay, provided they be situated near the sea. This is particularly the case in the West India islands. There is an exception to this observation in the interior of Georgia, where cotton grows very abundantly. Possibly the cotton of Georgia may be a particular species, and this idea is borne out by the fact of the Georgia cotton being much inferior to that of the sea islands.

Several species of cotton have been tried in Guiana, but none succeed so well as the loose and close seeded cotton. The last of these is preferred.

After the cotton has been gathered, it is dried in the sun until the seed becomes quite hard, otherwise it would heat and spoil. It in general requires to be laid out three days on a tile, or wooden platform, exposed to hot sun. The seed is then separated by passing the cotton between two slightly grooved wooden rollers, of a diameter of a quarter of an inch. These rollers are driven by treddles, put into motion by a negro's foot, whilst he presses the cotton between them with his hands. This machine is called a gin. A good workman can gin from 50 to 60 lbs. per day; but the labour is so great, that the same people ought not to be kept at work for more than a fortnight together. After the cotton has been ginned, it is carefully picked by women, who free it from broken seeds, dried leafs, or yellow locks of cotton. An expert woman will prepare from 25 to 30 lbs. per day. Some people switch it, and the cleaning is undoubtedly much facilitated by it, but as it has been disapproved of by the manufacturers, it has been very generally discontinued.

After the cotton has been thus cleaned, it is packed in bales, into which it is compressed by means of a screw. In this state it is sent to Europe, and employed for the various beautiful fabrics that do such infinite credit to British exertion and ingenuity. See Cotton Machinery.

It would be foreign to the object of the present article to enter into any details respecting the wonderful and beautiful degree of perfection at which our manufacturers have at length arrived. It may be sufficient to observe, that they far surpass those of any other nation, and that there is not the most remote chance of their being exceeded, until some country should unexpectedly call forth resources and treasures of which we cannot at present form even an imperfect conception.

Diseases of the cotton plant.

From the consideration of the plant in its perfect state, we naturally turn to the diseases to which it is obnoxious; and we have much pleasure in laying before our readers the observations which follow, as we have derived them from a gentleman whose high character and liberal attainment have long rendered him conspicuous among the few men of observation and talent that resort to the western hemisphere. To Dr Chisholm of Clifton we owe the whole of that valuable information which we are about to detail, and which he has afforded in the most liberal and generous manner.

The cotton plant is particularly attacked by an insect that receives the general name of chenille, or cotton caterpillar, and by a particular blight called the blast. Of the caterpillar we shall give the account in Dr Chisholm's own words: "The chenille, or cotton caterpillar, is generally about an inch, or an inch and a half in length. Its general appearance is beautiful. A single line of white runs down the whole length of the back, and a double line of the same colour parallel to this runs down each side; the intermediate spaces of the back and sides are of a fine glossy black, covered with soft down, intermixed with short black bristles; the belly is yellow, inclining to white; and the respiratory organs are in number double that of the rings composing the body, viz. twenty. The head is rounded, black and corneous, and armed with two lateral corneous jaws, constituting a cutting forceps, of most rapacious and destructive power. I have reason to believe, that this species of the phalæna has not been hitherto described by entomologists; at least I do not find in Linnæus, and the other writers on the subject I have consulted, any thing. Until, therefore, a better is given, I offer the following character:

Phalæna geometra seticornis alis omnibus subgriseis subangulatis deflexis.

Larva subpilosa, setulis nigris interpositis; 12-poda, 20-annulata, dorso nigro nitido, linea dorsali, lineolis geminis lateralibus flavescentibus albis—abdomine albo flavescente. Pupa obtecta, subovalis, fusca-nigrescens, coriacea.

Habitat in Guiana, Gossypii variis, forsan omnibus, speciebus, quarum folia petiolos fructusque etiam immaturos mira diraque voracitate, devorat.

One of the most singular circumstances respecting this species of the phalæna, is the uncommonly fragrant smell which issues from the plant on which it feeds, although neither the animal itself nor the plant is possessed of any fragrance separately. I have often endeavoured to ascertain the cause of this singularity, by bruising the insect, and the leaves of the cotton tree, but without being able to perceive any remarkable peculiarity of odour. So powerful, however, is the odour produced by the ravages of this caterpillar, that it may be perceived more than a hundred yards from the plant. Another equally singular circumstance is the manner in which the ova of this insect are preserved—a circumstance, until of late, extremely puzzling to the entomologist. A whole year may occur sometimes without any appearance of the chenille; and notwithstanding this, the year immediately following may be marked by the most extensive proofs of its voracity. Where, in the mean time, are the ova preserved? Some curious planters, with a view to ascertain this point, and to destroy the brood of so pernicious an insect, have cut down and burnt the cotton trees, on which we must suppose it deposits its eggs, and have also burnt the grass, and every other vegetable production of the land which it has infested; but without being successful in preventing a renewal of the ravages of the insect on the new plant on the following year. Infusing the seeds in the strongest brine and decoction of tobacco has been resorted to with a similar result. The ova of this species of phalæna seem, therefore, to be of the nature of those which may remain long unchanged; whose fecundation may require the agency of a very considerable degree of heat; and whose vitality may resist the power of chemical agents, and the fervour of ignition itself. Until this ideosyncracy, if I may so apply the word, of the ova of certain tribes of insects was discovered, the permanency of the brood of the cotton moth, notwithstanding the application of fire to the plants on which they have been deposited, was considered as altogether inexplicable. The discovery of Spallanzani, more especially, has thrown light on this singular quality, which completely divests it of mystery, whilst it raises our astonishment to a tenfold degree. The observations of M. M. Humboldt and Bonpland have confirmed the fact; and the ingenious and learned Mr Good, were more wanting, has, by some very curious additional facts, established the knowledge of this most wonderful economy of nature. See Mr Good's *Anniversary Oration before the Medical Society of London*, March 1808, p. 30—34.

A third curious observation relative to the history of the cotton moth and caterpillar, is the rapidity with which it carries its ravages to distinct and even distant fields of the plantation. We should indeed be inclined to imagine, that the wind has much agency in spreading its destructive progeny; for, in the course of a single night, whole fields, consisting of from four to ten acres, hitherto unmolested, have been devoured by them. Or does this proceed from the flight of myriads of the insect in its perfect state to distant fields, and then depositing their eggs, whose fecundation is quickened by the fostering heat of a favourable season, and thus giving rise to these sudden and astonishing colonizations. That the leaves of the cotton tree are the nidi as well as the food of the chenille is evident, from operations of the caterpillar when preparing for its change into the pupa state. By means of a thready substance resembling a spider's web, of a white colour, the leaf which the larva intends for the scene of its transformation is drawn together, so as to form a funnel-shaped fold, close at the edges, and shut up at the broadest part or base. The pupa is inclosed in a covering of the thready substance, and acquires its perfect form, or image, at the expiration of nine days. The moth is small, never exceeding an inch from the head to the extremity of the wings, of a gray, inclining to black colour. Immediately after dusk, in those seasons which are unfavourable to their propagation, myriads approach the candles, and are very troublesome, but soon terminate their existence in its flame. The period of their existence, when not destroyed by such causes, is about nine days; and the whole life of the insect, including all its transformations from the ovum to the death of the moth, is about twenty-seven days. In the pupa state, the insect is subjected to the rapacity of several other insects. Those I have more particularly observed, are a small species of apterous bug, I believe the *cimex grylloides*, and the common red ant. These are often found in the hollow folded leaf, having the means of disengaging themselves from it by a cylindrical passage penetrating to the helpless pupa, of which, when these insects infest it, nothing remains but the shell, or coriaceous coat.

The evolution of the larvæ, and the transformations and death of the insect, or the appearance and disappearance of the chenille, are certainly regulated or influenced by particular states of the atmosphere, and by the phases or changes of the moon. The chenille, or larva of the cotton moth, generally appears, in years favouring the fecundation of its ova, in July or August, a few days before the new moon, increases during the increase of the moon, and nearly about the full moon begins to disappear, and soon after ceases altogether. Happily for the planter, however, this happens only every second or third year. But in years uncommonly favourable, the chenille thus appears and disappears every month from July to October, and afterwards from the middle of January to the beginning of March. How are these changes effected? How should the action of the moon's greater or less pressure influence the propagation and destruction of this insect? Is it because there may be a natural provision for the insect, by the flux of vegetable juices, during the increase of the moon? Or finally, is it because there may be then a peculiar temperature of the air more favourable to the fecundation of the ova of the insect? These propositions involve disquisitions of infinite latitude and obscurity; therefore, instead of attempting to institute a theory capable of explaining these phenomena, it will be more useful to state the circumstances which have occurred during my residence in Demerary, at the periods of their appearance and disappearance, and leave to the judicious reader their application.

During the month of January 1801, the weather was clear, dry, and pleasant, till the 23d, with a temperature marked by 84° of the thermometer. The 23d and 24th were cloudy and rainy, with westerly and southerly winds, and the thermometer sunk to 82°. The remainder of the month was pleasant, with strong breezes at north-east and east, and thermometer 84°. The changes of the moon were as follows: New moon 14th, 1st quarter 21st; full moon 29th; rain 15.23. On the 28th, the chenille was perceived on several parts of the coast.

February began with rain and a low temperature; thermometer 80°. From 3d to 21st pleasant; wind rather boisterous, at north and north-east, and thermometer generally 83°. The remainder of the month chilly and extremely rainy, with variable winds, and thermometer sometimes as low as 76°. New moon 12th, first quarter 20th, full moon 28th. The chenille appeared on Success plantation on the 19th, and towards the end of the month was most destructive.

March was showery during nearly one half, the other half dry. Thermometer from 80° to 86°. No chenille appeared.

In these months the appearance of the chenille seems to have been regulated by the weather and the state of vegetation consequent thereupon, as well as the changes of the moon; for it came on when rains had rendered the cotton trees succulent, and when the moon was in the increase. There seems to be something at the period of spring when the chenille entirely disappeared; the month of March particularly inimical to the insect; for I have never seen it later than February.

The month of July, until the 9th, was pleasant, with occasional showers. Wind north-east, and thermometer 86° to 87°. The remainder was constantly rainy; it was also distinguished by a very extraordinary quantity of lightning in the south-west, from which the wind also blew. On the 15th thunder; thermometer from 80° to 87°. New moon 10th, first quarter 18th, full 25th. The chenille first perceived on the 15th, and increased till the 24th, and entirely disappeared about the 29th.

No rain in August till the 18th, but a good deal of thunder and lightning in the west on the 11th and 17th, wind north-east, and thermometer 86° to 88°. The remainder of the month generally showery, and once heavy rain on the 18th, but much thunder and lightning, and thermometer varied from 78° to 88°. The whole month was remarkable for coruscant lightning in the evenings, land winds and heavy dew at night. New moon 9th, 1st quarter 17th; full moon 23d, last quarter 30th. Chenille appeared on the 9th, and increased much towards 16th, and on 23d disappeared altogether.

September was generally pleasant and dry, although much thunder and lightning. Thermometer from 86° to 88°, wind north-east. New moon 8th, 1st quarter 15th; full moon 22d, last quarter 29th. On the 3d, the chenille began to appear, and by the 10th universal on the whole coast, from Demerary to Bubiu rivers, and so destructive, that the cotton trees were bared entirely of their leaves. On 15th chenille gone, and on 20th trees beginning to recover.

On the 7th October, an eclipse, with a strong gale west and south-west, some rain, and general haze. Almost all the rest of the month dry, and thermometer from 86° to 88°. But the whole of the month remarkable for thick fog all night and morning, more especially from the 8th, the smell of which was particularly offensive. The atmosphere charged with hydrogenous gas and very oppressive. New moon 7th, first quarter

14th, full moon 21st, last quarter 29th. The chenille on the 4th perceived partial on several spots of Success. Towards the 10th, instead of suddenly disappearing, and the pupæ being exhibited in the manner I have described, the larvæ were universally seen languid and motionless; and on the 15th they were every where dead and putrid on the leaves.

In the months of July, August, September, and October, we perceive the same causes giving life and activity to the chenille; and until the 10th October we also see that the ova were deposited and fecundated into a fresh brood of the insect at the same periods of each month. There are two circumstances particularly remarkable in this period, which do not seem to have existed in the preceding spring; the first is the astonishing quantity of thunder and lightning, and more especially of that kind of corruscation, which, from the time of the day in which it occurred, may be called crepuscular lightning. This was more especially observed on the 15th July, and on that day the chenille was first perceived; it is also singular that this did not seem to be regulated by any change of the moon. The same species of lightning also occurred in August, and was nearly concomitant with the reappearance of the chenille. The second circumstance is the extraordinary fog in October, attended with an offensive sulphureous or hepatised smell. This had not been observed by me before; but its effect on the chenille seems to have been wonderfully great. The impregnation of hydrogenous gas commenced on the 8th, and on that very day the chenille began to languish, and by the 10th scarcely an insect remained alive, nor were there the usual depositions of ova, nor apparently any provision made for a succession of the animal. This is certainly a phenomenon of uncommon importance, because it points out, with tolerable certainty, the best means of destroying the chenille; and gives stability to what has hitherto been little more than speculation, viz. that the vapour of burning sulphur is the appropriate remedy for the evil.

The consideration of the foregoing particulars seems to lead to the following inferences: 1st, That lightning and thunder dissipating obnoxious vapours, particularly those of a hepatised and hydrogenous nature, and thereby rendering the atmosphere more capable of aiding the process of vegetation, favours the fecundation of the ova, and the future progress of the insect to the perfect moth state, by providing a fostering heat, and a larger quantity of appropriate nourishment. 2d, That the accumulation of hepatised and hydrogenous gas in the atmosphere, by checking the process of vegetation, and by having a direct morbid action on the organs of the chenille, is inimical to their existence, and to their future generation. 3d, That it is probably for this reason that moderately dry weather, with north-east and easterly and south-easterly winds, when the vegetation of the cotton plant is most vigorous, favour the developement of the insect, and that southerly and westerly or land winds, tend towards their destruction; the former being pure and uncontaminated by any noxious impregnations, and seem rather, if different from pure atmospheric air, to be superoxygenated; the latter, on the contrary, always more or less loaded with hydrogenous or hydrocarbonic and hepatised gas, and being not only destructive to the chenille, but in the highest degree injurious to the human constitution.

Although the planters anathematise this destructive insect, with all the virulence of Ernulphus, it does not appear that any thing effectual has been attempted to prevent or destroy the evil. It is, however, of so serious and important a nature, that something should be done. Analogy points out the use of sulphureous vapours for this purpose, and the direct effect of similar vapours naturally applied to the chenille, confirms the propriety of the remedy. The only objection to it of any weight I have ever heard proposed, is founded on the supposed expence in purchasing the apparatus, and on the labour required for the effectual application of it to the trees individually; for in no other way can it be made effectual. But the judicious and truly economical planter finds that the calculation of these gives a result rendering them extremely trifling, when compared to the prodigious loss sustained by permitting the evil to exist. A small chaffing dish on which the sulphur is burnt, and a painted canvass cone to be placed over the tree for the purpose of concentrating the vapour, are all the apparatus required; one person to hold the chaffing dish under the tree, and another to place the cone over it, are sufficient for each tree; and ten minutes application of the vapour, is all the labour. Now, if a gang of 200 negroes, for all sexes and ages may be employed in this work, are put into a piece of chenilled cotton, with 100 sets of the apparatus, they will destroy the larvæ and pupæ spread over an acre in one hour, supposing the acre to have 600 trees growing on it, which is the usual calculation.—One acre of cotton trees in full vigour, and uninjured by the evils to which the plant is subject, will yield 400 lbs. of clean cotton, which at a medium price will sell for £40 sterling. The apparatus may be estimated at £60.—So that the expence bestowed on the destruction of the chenille of ten acres, the probable amount of a day's labour of a gang of 200 negroes, will not exceed, including the first cost of apparatus and the hire of the negroes, £80; while the produce of the land gained by this expence will be £400, leaving a balance of £320; and the second ten acres thus treated, as there will be no charge for apparatus, will consequently give a clear gain of £380. But if we consider that if the remedy is not applied there will be no produce, the magnitude of gain may be estimated at a much higher rate. The adoption of this remedy should therefore on no account be neglected.

A prudent economical planter will increase the brood of every species of domestic poultry, particularly turkies; for this has a tendency to diminish the brood of chenille in a very great degree, while profit arises from the augmentation of useful stock. Turkies are observed to have a remarkable appetite for the larvæ of the cotton moth, and devour prodigies quantities of them. But the most usual natural enemy of the chenille is the bird called in the colony Chenille bird, (the black and yellow Manakyn of Edwards, or the Pipea aureola of Linnæus,) and the Certhia familiaris or house wren, and the Parus Niger of Linnæus, mentioned by Dr Bancroft, (*N. Hist. of Guiana*, p. 182.) The former of these appears on the coast with the chenille, and quits it at the same time it does, and the flocks are numerous in proportion to the quantity of the insect.

A remedy has been proposed and tried in England for caterpillars, slugs, grubs, and other insects infesting fruit trees and vegetable esculents, with considerable success. I saw the experiment made by a gardener of the name of Macpherson at Bath, and I had much reason to approve of it. I therefore recommended it to my friends in Demerary, but I believe unavailingly, and for the reason which constitutes so frivolous an objection to the fumigation with sulphuric vapour. It possesses the merit of simplicity, being nothing more than the scattering of finely powdered quicklime over the leaves of the trees and plants on which the insects are, early in the morning when they are moist with dew. If any particles of the lime adhere to the insect, it inevitably perishes.

The blast or blight is another evil the cotton tree is subject to; and as its tendency is to check or destroy the vegetative powers of the plant, and consequently to deprive it of all its productive faculties for a season, it is perhaps an evil of greater magnitude than even the chenille. I shall therefore, as I have already attempted relative to the chenille, present such observations as have occurred to me, during my residence in Demerary, as a planter, on the nature, causes, and means of remedying it.

The magnitude of the evil, and the causes to which blast or blight was anciently assigned, Pliny thus expresses, (*Nat. Hist.* l. xviii. c. 17.) *Cœleste fragum vinearumque malum nullo minus noxium est rubigo. Frequentissima hæc in roscido tractu, convallibusque ac perflatum non habentibus. E diverso carent ea ventosa, et excelsa.* In another place he enumerates the names the blight was distinguished by, (c. 28.) *Aliis rubiginem, aliis uredinem, aliis carbunculum appellantibus, omnibus vero sterilitatem.* Of these appellations, *uredo* is perhaps the most applicable, and most expressive of the appearance of plants suffering under this disease. The cotton trees more especially look as if burnt, the leaves, stem, and pods exhibiting the marks of a scorching fire. Pliny seems to have possessed a perfect knowledge of the causes of blight, when he thus speaks of them; *Plerique dixere rorem inustum sole acri frugibus rubiginis causam esse, et carbunculi vitibus: quod ex parte falsum, arbitror, omnemque uredinem* frigore *tantum constare, sole innoxio. Id manifestum fiet attendentibus. Nam primum omnium non hoc evenire, nisi noctibus et ante solis ardorem, deprehenditur.* (*Ibid.* Ed. Harduin, folio). The very accurate observations of Ramazzini have given precisely the same result, and proved the efficiency of a cause exactly similar in effect to that which I shall describe in Demerary. In the year 1690, in Modena and the contiguous districts of Italy, prodigious rain and consequent inundation took place. *Perstitit deinde eadem pluviosa constitutio, non solum toto veris tempore, sed per totam fere æstatem ut nulla pene dies sine pluvia visa fuerit. Hinc factum, quod* una cum pluviis flante ut plurimum Borea, *nulla unquam æstas nostro in hoc climate exstiterit, in qua remissior fuerit caliditas, &c.—Sub initio Junii denuo, sicut anno anteacto, apparuere signa Rubiginis.* The whole vegetable kingdom suffered by this *pessimus omnium frugum morbus*, &c. (See Ramazz. *Constitutio Epidemica Ruralis*, 1690. *Oper.* Ed. 1718, p. 69, 70.) That this has been chiefly efficient in the production of this disheartening calamity in Demerary, will appear from the following detail of facts; and it is the more deserving our notice, as it goes far to prove the identity of disease produced in the temperate and tropic climates, in countries distant from each other more than thirty-eight degrees of latitude, by a cause of precisely the same nature, and which, in relation to each country, acts with precisely the same degree of power.

During the spring of 1801, an opportunity, fatal to the crop of cotton, afforded ample means of ascertaining the causes and nature of blast, and gave room to believe, that a remedy is not impracticable. Early in the month of November, the rainy season was anticipated considerably, and presented a prospect extremely discouraging to those planters who had been late in pruning their cotton trees, which, owing to that cause, had not as yet arrived at maturity. Success estate was precisely in this predicament. The consequence in general was, the trees in most instances became sickly, and the pods reluctantly opened to a solar heat seldom exceeding 80° and 82°. During December, more than two feet of water fell and inundated the fields; and scarcely had we emerged from this calamity, when in January another flood reduced us to the same situation. Distressing as these circumstances were, the immediate consequence would not have been fatal, had no other succeeded. The trees lost nothing of their verdure and towards the end of the month, a pleasing and universal display of blossoms raised apparently well-founded hopes of an ample second crop. About the 28th, however, the chenille began to appear, and towards the middle of February became very general on the estate, when a third prodigious fall of rain contributed to shake the hopes we had formed. Notwithstanding this succession of unfavourable events, the cotton trees being vigorous, and throwing out an immensity of blossoms, I still flattered myself, that the second crop would compensate the loss of the first. Towards the end of February the north wind set in, and frequently sunk the thermometer to the 70th degree. This was decisive; for, although the month of March was showery, yet it was very considerably warmer, and the trees exhibited a yellowness of leaf, a dried as if scorched stem, the blossoms and forms fell effæte, the pods approaching to maturity acquired a black hue, and their foot-stalks becoming shrivelled, sapless, and at last rotten, afforded no longer a support, and they also fell hardened, black, and useless. The preceding year having been marked by a series of circumstances, the very opposite to those I have described, was also marked by the wonderful fecundity of the cotton trees during the months of February, March, and April. The one year gave a crop of near a hundred thousand weight; the immediately following one, a crop of fourteen thousand, of bad, scarcely marketable, cotton.

In the consideration of these facts, we perhaps may perceive the causes, the nature, and in some measure the remedy of the blast. The late pruning had deprived the cotton trees of sufficient time to acquire that state of maturity, which enables them to yield their fruit abundantly, when heavy rains, and the accumulation of water round their roots, surcharged them with juices, and created a fresh and overpowering *spring*, retarding the opening of their pods. At length a plethora took place, and the fruit was destroyed, without materially injuring the trees. Whilst recovering from the effects of this, a new morbid cause interposed, and again reduced the trees to the necessity of casting off their immature fruit, and to a disease of a still more formidable nature invading their whole structure. The state of the atmosphere towards the end of February, had allowed the irritability of the trees to accumulate, (to use the language of the late Dr Garnet,) and the heat of March acting upon this morbidly accumulated irritability, overpowered it, bringing on a state of exhausted irritability and gangrene. Had the same temperature of atmosphere continued, no such fatal event could have taken place. Hence the causes of the blast of cotton trees appear two-fold,—an excess of vegetation, corresponding with plethora in animals, and exhaustion of vegetation, terminating in a state similar to gangrene: the first followed by the destruction of the fruit only; the second by the almost total destruction of the plant, which recovers its health and functions only by pruning and a favourable season. The reasoning of Dr Garnet, as it relates to the last of these diseases, is perfectly applicable to the blast of the cotton trees of Demerary. "I am pretty well convinced," says he, "not only from a number of facts which I have myself observed, and which I have stated fully in my Lectures, but also from the observations of Uslar, that blight *is almost always* a species of gangrene or mortification, brought on by the action of the rays of the sun in the spring on the morbidly accumulated irritability, which had been produced by a considerable subtraction of heat during the night. A frosty night succeeded by a cloudy or misty morning, is never attended with those effects which almost certainly follow, if, when the spring is considerably advanced, a frost should be succeeded by a fine warm morning." The difference of temperature in Demerary, between 88° and 70°, suddenly applied to the cotton trees, will produce the same effect, as a frosty night (36°) succeeded by a warm morning (54°) on the fruit trees of the north of England. In both countries, it is the *rapidi potentia solis acrior*, followed or preceded by the *boreæ penetrabile frigus* of Virgil, *adurans*, or burning, or blasting the trees. Thus heat and cold are relative terms; and, in the present instance, that degree of the latter which in Great Britain is called frosty within the tropics, is, to our senses, greater than the medium summer heat of the former country; and that which constitutes what is considered a fine morning heat in the one, would be altogether unsupportably cold in the other; nevertheless, the power of the corresponding temperatures in both countries is precisely the same, producing the same mischievous effect.

There is another cause of blast, which exists in countries circumstanced as Demerary is, and which arises from the structure of the plant itself. I mean the destruction of the root of the cotton tree, or the injury it receives when, from the circumstances of the situation in which the plant is placed, the root is continually, or for a considerable length of time, immersed in moisture. The cause of injury proceeding from moisture thus applied, is the structure of the root, which is somewhat fusiform or tap-rooted. This is proved by a simple experiment. Let several rows of cotton trees be planted on a gently sloping dam or mound of earth, at the foot of which is the water of a ditch or trench, in such manner as that the rows shall be gradually elevated above the surface of the water. When the plants have grown to a considerable size, let them be taken up; and the result shall be, that those nearest the water shall have no tap root, but evident marks of its having been destroyed by disease; the next in height shall have a small portion of tap root; and so on to the most elevated, which shall have the tap in a complete healthy state. These plants in their parts above ground, shall exhibit a vigour proportioned to the perfect state of the root, and consequently to their elevation from the water. Sometimes however, nature, with her usual compensative economy, gives either a new direction to the root, or gives the plant a capacity of receiving from the atmosphere, that nourishment which makes up for the deficiency from the earth, or those remedial fluids which counteract the baneful influence of excess of moisture; for, in many low situations, I have known the cotton trees to yield abundantly.

Before I conclude this part of my subject, I may observe, that a deficient nourishment of the cotton tree, after a long tract of very dry weather, produces an effect in many respects similar to blast. But this effect, in truth, is no more than similar; and the difference is made apparent by the supervention of moderate rains. Here there is no exhausted irritability, no positive hurtful power, but a subduction of the necessary supports of life: moderate nourishment gives renewed vigour to the plant, and enables it to yield abundantly. The period from July to November 1801, afforded a striking illustration of this; scarcely any rain fell during the whole of these months, whilst the chenille devoured the leaves, leaving the stem and branches completely striped until September, and very little cotton was produced. In November, moderate showers recovered the cotton trees; and the heavy rains of December, instead of injuring them as they did the preceding year, gave them a great addition of health and strength, and enabled them to produce most abundantly. This is proved by the cotton picked during these months; in October 7053lb. in November 13,826lb. in December 53,972lb. This was, in fact, among vegetables, a case correspondent to that of famine, or accumulated irritability among animals, so finely illustrated in the ingenious remarks of Dr Thornton on the state of the crew of Captain Bligh's boat, (*Med. Extracts*, vol. iii. part 3. sect. 44.)

In the consideration of the pathology of plants, we are much assisted by bearing in mind the analogy which may be perceived between the diseases of plants and those of animals,--a branch of agricultural knowledge of very high importance, but in which it must be confessed hitherto little progress hath been made. The causes, symptoms, and cure of both, come under the general principles of medicine; and by applying these principles, as they relate to the latter, to the former, we shall find an unexpected facility in the developement of the ratiocination on which their prevention and cure depend. Thus, if the disease of the plant proceeds from plethora, depletory means may go far to cure it; if the disease arises from direct debility, the gradual admission of stimuli, or of those means suitable to the nourishment of the plant, will effect the restoration of its vigour; but if, on the other hand, the disease is gangrene or a state of exhausted irritability, we must submit; and our exertion then must be directed to preserve the trunk and larger branches, and prepare them for a new growth, or a renovation of their vegetative powers at a future season, for the means of immediate recovery are not in our power. I have said, that the excess of the excitement of the cotton tree, proceeds from a redundancy of moisture or water; the cure therefore, is evidently the quick discharge of that water, by the enlargement of the sluices or outlets of the plantation, or by having, what is called in Demerary, a deep drainage. Should circumstances prevent this from being immediately effected, which often happens, owing chiefly to the nature of the soil, it is, at least, in the power of an active and judicious planter to prevent the recurrence of the evil. Besides the usual means of deepening the channel into the sea, and fencing the windward side of it against floating mud, and putting in larger kokers or flood-gates; there is another, which, without due attention to the operation of it, may be considered visionary, and that is a steam-engine so placed as to throw the water it raises over the front dam into the sea. The expence of purchasing constitutes the only objection of weight, and should that be got over, the efficiency of the remedy must stand confessed. Upon the whole, however, a secure and ample drainage should be the first object on a Demerary plantation, for it is by that almost alone that this species of blast can be prevented or cured.

The privation of moisture, and the destruction of the organs of exhalation and inhalation of the plant, the leaves, by the caterpillar, are great evils, but of infinitely less magnitude than the excess of moisture. They have their remedy. In situations where the continuity and level of surface are not interrupted, as is the case generally on the sea-coast of Demerary, beyond the cultivated grounds, a supply of fresh water may, by the exercise of a little industry, be at all times obtained. By carrying a small canal about a thousand roods into the interior country, where the surface is in its native state, covered by a thick coat of a spongy vegetable substance, (Pagass), at all times charged with fresh water, a constant flow of this most necessary article may be maintained, sufficient to irrigate the fields, and to supply the negroes with drink. An excellent man, and a good though speculative planter, Mr Post, exemplified the practicability of this resource in a most remarkable and most benevolent manner, in the very long dry seasons of 1801 and 1805. In the case before us, the usual method resorted to, is to admit a certain portion of salt water into the trenches, the effect of which is strongly to stimulate the cotton trees, and a general blow, or bursting of pods, often ensues; but this method requires so much judgment in the employment of it, as to render it very generally dangerous—too great a supply excites the trees to an effort which soon proves fatal to them. This, in fact, is a fine illustration in vegetables, of the doctrine of wasted excitability in animals; the result is precisely the same in both; for, to use the language of Brown, "no means of reproducing the healthy state, that is, the proper degree of excitement, is left, but the very circumstance that occasioned the waste, that is, already an excess of stimulant operation, not admitting of more stimulus."

It is unnecessary to offer any observations on the third state of disease of cotton trees, the subduction of excitement or gangrene, or what, in strict propriety of language, is blast or blight; it is a state truly irremediable. All that can be done, must be done in the way of prevention; and an attention to the means of curing the first state of disease, will in a great measure prevent this, viz. good drainage: for if the excess of excitement is prevented from taking place, or obviated should it take place, there will be the less danger from the sudden subduction of it.

Upon the whole, a judicious system of cotton planting, including the various operations of draining and cross-draining, if necessary; of levelling and open planting the land (squares of six feet); of taping, singling, and weeding, the young cotton fields; of weeding, pruning, and dressing, the old trees, on or before the first of June; of deepening and clearing the drains before the actual occurrence of the dry season in August; of providing as much as possible the means of irrigation in long tracts of aridity;—these, I say, together with a general attention to the course and succession of the seasons, and to the phases of the moon, will be the most certain means of preventing the various evils of plethora, debility, and gangrene, in the cotton trees, or curing them should they unhappily prevail.

Before I conclude, however, I may observe, that there is another species of blight which arises from lodging the seed in imperfectly drained land. This is a species peculiar to Demerary, and countries whose soil is naturally surcharged with water, but does not come precisely under the class of diseases occasioned by plethora and destruction of the sap root, although nearly allied to them. Cotton planters say that in such land, the plant is sickly from a *sour water* which remains in it until it be completely drained. They are not aware of the propriety of the expression; for the sickness of the plant, in truth, is produced by the basis of acidity. The water becomes decomposed, and the earth absorbs hydrogen, and the disengaged oxygen mixes with the atmosphere, and enters in the composition of the vegetable growing in the soil, which thus become superoxygenated, and perish from that cause.

A constant attendant on blast, or when the cotton has even a tendency to blast, is an insect, called by cotton planters the cotton bug. Thousands inhabit the pods when the plant is in a diseased state, and seem to contribute much to its destruction. I have reason to believe that this insect has not hitherto been correctly characterised. It is certain that Dr Brown has failed in doing so, and both he and Mr Hughes, the historiographer of Barbadoes, have confounded it with the moth and the bruchi, which are inhabitants of the cotton tree in any state. Dr Brown calls it a cotton fly, and distinguishes it thus, *Bruchas kermesinus maculis nigris notatis elitrarum extremis fuscis.* Although this description corresponds precisely with the natural appearance, figure, and form of the cotton bug, it certainly is by no means applicable to the bruchus; and when he adds, "the caterpillars of these flies are frequently pernicious to the cotton bushes, and often destroy whole fields of the most promising plants in a short time," he confounds it with the moth. The cotton bug is really a species of cimex, unnoticed by Linnæus, and belongs more particularly to the oblongi. It may be distinguished by the name of the plant it inhabits, (*C. Gossypioides*), and its character is that I have quoted from Brown. The young bugs are scarlet, and inhabit the blasted pods of cotton. The full grown bug is that described by Brown, and possesses (when bruised) all the offensive fœtid smell of the domestic bug (*C. Lutalarius.*)

Such is the natural history of the cotton, and its diseases, in as extended a form as our limits admit. We now shall conclude with a rapid sketch of its commercial history

Cotton was known to the ancients, and is particularly described by Pliny. We have not, however, been able to discover the mode of its manufacture in those early periods. The beauty of the substance, and its obvious applicability to many purposes, would no doubt excite a very early attention; but it was not until the wonderful facilities which were introduced into the spinning of the raw material, that it became an object of extensive cultivation by Europeans. In India, indeed, where the cheapness of labour always counterbalances, the necessity for much manual labour, it has been long cultivated and manufactured into muslins and calicoes, by the simple apparatus of the inhabitants. England boasts of having introduced the improvements in machinery which have rendered cotton an object of immense attention to Europeans. Ever since the West Indies have been settled by Europeans, it has been partially grown; but it was confined to few situations, as other colonial produce was more marketable. The British West India islands for a long time supplied nearly the whole of the British demand. About thirty years ago, the Dutch settlements on the coast of Guiana attracted the attention of cotton planters, and nearly at the same time the southern states of North America engaged in similar pursuits. Still more recently, the Brazilians and Spanish Americans have actively cultivated cotton; so that the quantity now produced in the western hemisphere, in Africa, the south of Europe, and in Asia, is incredibly great, and may be augmented in an indefinite proportion, provided that there was any market for it; but like every thing else for which there has been an unexampled demand, too much is produced, and its value has decreased in a corresponding ratio.

The East India cotton, the Pernambuco, the Sea Island (American) the Demerary, Berbice, and Surinam, are the cottons most valuable for the finer purposes. The West India island, the Bowed Georgia, and some kinds from the Levant and the East Indies, are fitted for coarser purposes. The quantities of cotton which have been consumed by the British manufacturer are enormously great, and have been gradually increasing; of which we may form some estimate, when we recollect, that the quantity in 1784 was perfectly insignificant, and that the estimated consumpt of the current year is about seventy millions of pounds.

The expence of cultivation varies very considerably in different situations, and it will be found to be most reasonable in India and in the Americas, while it will be seen to be greatest in the British colonies, owing to causes which we shall afterwards notice. In the British colonies, particularly in those captured from the Dutch, on the coast of Guiana, the capital vested in every acre of land devoted to the cultivation of cotton, (in this the actual price of the land, the slaves, buildings, &c. are included), amounts to about L. 150 sterling. Each acre, as has been shewn by an average of ten years, produces about 200 lbs. net of cotton. From averages taken from plantations, the expence merely of cultivation amounts to 7d. per lb. while the mercantile charges, including the duties, amount to about $7\frac{1}{2}$d. more on each pound; so that the whole expence on every pound of cotton is not less than 1s. $2\frac{1}{2}$d. The average prices from the year 1784 to the present time, have varied very much, having been at one time (in 1808) as high as 3s. and at another below the actual cost, which we have already shewn to be 1s. $2\frac{1}{2}$d. During the same periods, war duties have been imposed in very different proportions on different kinds of cotton. For a considerable part of it, American cotton paid a smaller duty than that grown in the British colonies. But our readers will form more accurate notions on this point by glancing over the subjoined Table.

Table of Duties on every 100 lbs. of Cotton, since first Imposed.

Period.	British.	North American in American bottoms.	Foreign generally.	Brazil in British ships.	Brazil in Brazil ships.
	s. d.	s. d.	s. d.	s. d.	s. d.
July 1799 ... September 1801	8 9	6 6	12 6		
May 1802 ... July 1803 ...	10 6	7 10	15 0		
July 1803 ... April 1805...	16 8	17 8	25 0		
April 1805... July 1808 ...	16 10	17 10	33 10		
July 1803 to the present time	16 10	20 5 or 21 $1\frac{1}{2}$	33 10 or 25 $3\frac{1}{2}$	16 10	25 2

These are the general rates, but more or less is paid according to the mode in which the cotton is imported. It is needless to enter into any details respecting the injustice which has been exercised towards the British cotton grower; but it may be well for us to point out, as rapidly as we can, the various oppressive restrictions, that increase the expence of his establishment far beyond that of any other cultivator of the same substance.

Before, however, we enter into this sketch, it may be well to give an outline of the expence of settling a cotton estate in Louisiana, which we have derived from an authentic and respectable source, and which will serve to render the contrast still more remarkable.

In Louisiana, 600 acres of land cost	L. 1575
30 slaves	2700
Oxen, horses, cows, and sheep	450
Total	L. 4725

These 30 slaves will cultivate 30,000 lbs. of cotton; which, if sold at $10\frac{4}{5}$d. per lb. will yield L. 1350.

The items of the annual expenditure are as follows:

Overseer, ...	L. 90 0 0
Carpenter, ...	67 10 0
Medical attendance, ...	9 0 0
Tools, ...	22 10 0
Clothing, &c.	67 10 0
Freight of crop to market, ...	22 10 0
Taxes, ...	5 12 6
Total, ...	L. 284 12 6

which deducted from L. 1350, gives a clear revenue of L. 1065; 7; 6 as a return for the original outlay of L. 4725.

The chief causes of the deteriorated condition of British cotton properties, are to be found in the nature of the connection which subsists between the colonies

Cotton.

and Great Britain, which seems to have been established solely for the purpose of benefiting the latter: we do not deem it necessary to enter into argument on the subject, but we shall state facts which speak for themselves.

The monopoly both of the supplies and of the produce to the colonies, is one of the chief sources of the high expenditure in cultivating cotton in the British West India possessions. This, however, has been adopted with a view of enforcing the ends of the navigation laws, and therefore are not to be opposed. Every article of clothing, of luxury, and even of the first necessity, is derived from the united kingdoms; unless, indeed, under the most distressing circumstances, when the governors of the colonies are authorised to open the ports to American vessels during peace. But in general no permission is granted. Now every article of food in America may be procured at one half, or even a third of the sum it actually costs when brought from England. The monopoly of the produce also is disadvantageous to the British cotton grower, particularly in the time of war, when he is obliged to incur all the war charges without any reciprocal advantage, while if permitted to choose his own market, the supply would be regulated, and the price be in consequence rendered equal to the expenditure.

This then is the predominant cause of the expense of cotton plantations in British settlements; and unless it be regulated, the British planter can never enter into competition with the foreigner. We might, did our limits permit us, enter largely into the subsidiary causes; but it is impossible to do so, without exceeding the object of this work. (C. M.)

On the different Kinds and Qualities of Cotton.

Different kinds of cotton.

COTTON is now so extensively used, as the raw material of a most extensive and useful manufacture of cloths of many different kinds, that a short account of the different kinds imported into the British market, with remarks upon their respective qualities, and the estimation in which they are generally held by the manufacturers who use them, may perhaps be the most useful introduction to the account which we propose to give in this article, of the various stages of this most extensive and beneficial application of British industry.

Smyrna wool.

Smyrna Wool.—This kind of cotton wool was formerly imported from the Levant, in quantities proportioned to the trifling demand which then existed for it, and was almost the only kind then to be met with, excepting a few bags occasionally imported from the West Indies. It is now rarely to be met with, the price which it commands affording no encouragement to the importer to trade in it. This is little to be regretted, as it is short in the staple* and very weak in the fibre. Although soft and silky in appearance, therefore, it is neither well fitted to undergo the fatigue of the many processes to which cotton is subjected in the course of manufacture, nor does it produce an article of either beauty, strength, or durability when finished.

West India.

West India.—The cotton wool of the West Indies is various in quality, but is in general a strong coarse article, pretty long in the fibre, and sufficiently well adapted for the manufacture of the stouter and coarser fabrics of cloth, to which it is generally applied. It is totally unfit for the lighter and ornamental goods.

East India.

East India.—No great quantity of this has ever been imported into Europe; the company perhaps considering a great importation of the raw material as likely to prove injurious to their more lucrative traffic in finished goods. What has been imported is very various. That known by the name of Bourbon is generally of a very superior quality, both in strength and fineness. It is still the only wool used for yarn of the finest kinds. A coarser kind of wool is also sometimes brought from India, generally in large square matts or bales. It is fine, silky, and glossy in appearance; but is so very short and weak in the fibre as to be hardly capable of being spun.

South American.

South American.—The wool brought from the different settlements on the continent of South America, ranks higher in general estimation than any we have hitherto enumerated, excepting the Bourbon. The chief kinds are the Brazil, which is distinguished by the names of Pernambuco and Maranham, from the districts where it is produced. The Pernambuco wool is rather short in the fibre, white in the colour, and in quality is superior to any imported, the Bourbon and Georgia excepted. The Maranham is similar in quality, but inferior both in strength and cleanness to the Pernambuco.

Demerary.

Demerary.—Which is a fine white glossy wool, pretty long in the fibre, and generally very well cleaned and picked before packing. It forms a clean stout yarn, and is very fit for what is of a moderate fineness, but it is too long and coarse in the fibre for very fine yarn. The Cayenne cotton is not much imported. It is a strong clean white wool; but the fibre being of uncommon length, it is found difficult to card and spin by the modern process. The others, viz. Berbice, Surinam, &c. are of the same general description, but inferior to those mentioned, and pretty nearly on a level in quality and price with the West India wools.

Georgia.

Georgia.—It is not many years since the cultivation of cotton was introduced into Georgia and South Carolina. Its superior qualities, however, soon raised it to a very high rank in the estimation of the British manufacturers. The Georgia wool is not the produce of the common gossypium or cotton tree, but of a small shrub, which after two crops decays and is rooted out. The Georgia is called either Sea Island or Bowed. The first is decidedly superior to any known, the Bourbon excepted. The Bowed Georgia is a short fibred weak cotton, inferior even to the West India wool.

To the above short account of the mercantile estimation in which the different kinds of cotton wool usually brought into the British market are held, we need only add, that perhaps a common price-current list will be found the best criterion to which we can refer as the standard of their respective values. But this must also be taken cautiously, as the prices are often greatly affected by casual interruptions of the supply, either from failure of crops or political vicissitudes. The coarse wools from our own colonies do not of course suffer the same interruptions as those belonging to foreign powers; and in point of quantity these furnish by very far the greatest proportion of the supply, from being applied to the coarser and thicker fabrics, which not only require the greatest weight of stuff, but from their durability are consumed by the great mass of the people.

Besides the vegetable qualities of the wool, a considerable difference in its value arises from the mode in which it is prepared for the market by the cultivator. In the Dutch settlements, that patient and laborious care for which those people are so remarkable in all

* By the word *staple*, cotton dealers and manufacturers mean the fibre or hair of the cotton.

Cotton.

their pursuits, is strikingly visible in the attention paid to picking their cotton. Hence the Demerary wool is generally considered worth perhaps ten or fifteen per cent. more, on account of the cleanness and uniformity of its quality, independent of its intrinsic value when compared with other cottons. It must be obvious, that the cleaning of cotton before it is packed, deserves, from the planter, a much greater portion of attention than it generally receives, when he considers, that the freight of much inferior stuff might be saved, and that he can command labour at a much cheaper rate than the British manufacturer, who must submit the cotton which he purchases to a very rigid and expensive examination, frequently abstracting from it one fourth of its weight before it is rendered fit for his purpose. That this may not be supposed overcharged, let us suppose a very common and not highly rated case.

One pound of Pernambuco wool costs . .	2s. 6d.
Picking 6d. per lb., 6 oz. waste 1s. . . .	1 6
	4s. 0d.

Clean cotton remaining 10 oz.; which, therefore, costs the manufacturer six shillings and four pence eight-tenths per lb. previous to all his subsequent operations, excepting a small deduction which he may obtain by selling the waste, or manufacturing it for some coarser purpose. Again, if we can suppose that the planter, from having his labour at a lower value, could have the same cotton picked for three pence per lb. with the same refuse or waste, and that he could sell it to the British manufacturer 20 per cent. lower than by the former calculation it actually costs him, he would receive five shillings and one penny per lb., saving upwards of one third of the freight and charges, and reserving his inferior cotton either for domestic uses or for traffic, as he found most advantageous. Simple as this statement is, much difficulty would, no doubt, occur in reducing it to practice; but the obvious absurdity of paying a high freight, and a war premium of insurance, for what is found totally unfit for use, must strike every person at first sight; and this hint is well worth the serious attention of those extensively interested in the prosperity and management of cotton plantations. The remark respecting the Dutch colonies is a sufficient proof, that there is nothing impracticable in it when care and attention are employed.

A general complaint has been made of the great room occupied on board ship, by the way in which cotton is packed in the bags, being merely trod down in the bags by the negroes employed on the different estates. To remedy this, compressing presses have been suggested as useful improvements, and a considerable number have been already ordered by West India merchants for the use of the planters. These presses, in shape, are not materially different from those used for the pressing of cloth in calenders, or that employed by printers and bookbinders for the compression of paper and books. The compression of cotton, besides the saving of room, must be advantageous to the cotton, in so far as it will prevent, in a great measure, that absorption of moisture of which it is so eminently susceptible, and by which it is so frequently damaged; but it will require rather more labour in beating to restore it again to a state fit for carding.

On the Cleaning and Picking of Cotton.

Cleaning, picking of cotton.

In the manufacture of cotton, the process first in point of order is the cleaning it from the seeds or gins. This process, more easily accomplished by hand than any other, and apparently the most simple, has, in experience, been found the most difficult of all to be accomplished by machinery.

It is of much importance, not only to the manufacturer, but also to the merchant; for by sending home the raw material, mixed with a large proportion of matter entirely useless, the expence of conveyance, already great from America, and still greater from the East Indies, is much increased. Could the cotton, therefore be cleaned to a certain degree abroad, without injury to its staple, it would be an evident saving to the merchant, and would lessen the labour, as well as the first cost to the manufacturer. For these reasons, the ingenuity of men has been excited to accomplish this desirable end.

How far they have been successful, we shall now endeavour to show, by describing a variety of methods which have been employed to clean the raw material, both by hand and by means of machinery.

Methods of Cleaning Cotton Abroad.

Methods of cleaning cotton abroad.

In the West Indies, and on the continent of America, what is called the roller-gin has been long used. It consists of a pair of fluted rollers, about $\frac{5}{8}$ths of an inch in diameter, and about nine inches long, the one being placed immediately over the other. These rollers usually receive their motion from the foot, by means of cranks and fly-wheels, somewhat similar to the movements of a common spinning wheel, or foot turning lathe.

The rollers draw on the cotton between them, and separate it from the seeds, for the diameter of the rollers is so small, that the gin cannot, when whole, be drawn in between them.

With one of these machines a negro will clean from 30 to 40 lbs. in a day; but after working it two days, he is commonly so much fatigued, that it becomes necessary for him to have a day or two to rest, before he is again fit for the same labour.

These machines are sometimes wrought by horses, but they are not so much approved of; because when the horse quickens his pace, the cotton is apt to be hurt by the rapid motion of the rollers. This objection, however, might be easily overcome by a mechanical contrivance, to prevent the rollers from moving too rapidly, however quickly the horse might go. The same may be said with regard to any other cattle mill.

This machine, when properly managed, performs its work in a very perfect manner, being found not at all injurious to the staple of the cotton. The great objection to it is, that the quantity which it will clean is very small; for this reason, in Georgia, it is used for the Sea Island cotton only, and other means have been adopted in order to save time.

The cotton called bowed Georgia, takes its name from a mode of cleaning cotton, in use probably long anterior to the invention of the machine we have mentioned. This was performed by means of the bow-string, which being raised by hand, and suddenly let go, struck upon the cotton with great force, and thereby served both to separate the gin and open the cotton, so as to render it more fit for the processes which follow the operation of cleaning. But this mode, whatever advantages it might possess in point of quality, has been abandoned for others better adapted to get through a quantity of work; and what is called bowed Georgia, has for a long time, in reality, been cleaned by means of a machine, distinguished by the name of a saw-gin.

This machine consists of a cylinder about the size of a weaver's beam, having, at equal distances upon it, wheels cut out like a saw. Hence the name of the machine.

Instead of these saws, the machine originally had wires like card-teeth; but these having been found to make what is called white nap on the cotton, the saws were substituted. These saws serve to pull the cotton through a grating, which has its openings so narrow, that the gins or seeds cannot get through them.

The grating is inclined to the horizon. Cotton is thrown upon it by the negro who attends the machine; the teeth of the saws pull through the cotton, whilst the gin rolls down the surface of the grating, and escapes by a spout in the side of the machine. Meanwhile, the cotton is thrown backwards by the centrifugal force of the motion of the cylinder, by another cylinder covered with brushes, moving with great velocity, and serving the double purpose of aiding the delivery of the cotton, and of cleaning the teeth.

This machine, although very expeditious, and not materially injurious to cotton of a short staple, is altogether unfit for cleaning long cotton; and is accordingly not used, as I have already mentioned, for the kind of Georgia cotton, known by the name of Sea Island.

One of these saw gins will clean about 3 cwt. per day.

It is worthy of remark, that when the Upland Georgia cotton was first brought to this market, it yielded a higher price by about 2d. per lb. when it was cleaned by the roller-gin; but, contrary to all expectation, it has been found, that for cleaning this species of cotton, the saw-gin is much better adapted; and the cotton done in this last way is now much preferred by those who understand the nature of spinning it. The saws separate the gin much more effectually than the rollers, and at the same time give it a kind of teasing, which is found highly beneficial. This fact is well worthy the attention of importers of Surat cotton, for to it the machine seems equally applicable.

Modes of Picking Cotton in Great Britain.

Modes of picking cotton in Britain.

Machinery has been applied in Britain in the cotton manufacture to a great extent, and has arrived at a degree of perfection almost incredible. Yet the simple process of picking has hitherto, in a great measure, defied every attempt to produce an effect equal to what is done by hand.

The method of picking by hand in this country, is to spread the cotton on a table, the upper part of which is formed of cords, and quite elastic. There it is beaten by slender rods. The effect of this process is somewhat similar to the bow-string, and most of the seeds fall through between the cords; those which may remain are afterwards taken out by the fingers.

This mode of cleaning cotton renders it fit for the finest purposes; for while it opens it thoroughly, and makes it perfectly clean, it does not break the staple. Machinery of various kinds, however, has been tried, in order, if possible, to lessen the expence of this process, some of which I shall now describe.

1st Machine. The cotton is laid on a cloth, which passes over two rollers; and these having a motion communicated to them, feed forward the cotton. This contrivance is called a feeding-cloth.

From the feeding-cloth the cotton is taken by a pair of rollers, toothed like a coarse rasp; these having a slow motion, and pressing the cotton between them, feed it forward to what was called the comb, consisting of a number of pikes or teeth, and, having a reciprocating motion, tears the cotton from the rollers. This part of the machine is now called the Devil.

This machine, however, tore the cotton in pieces, and was but little used, except in the spinning of coarse weft upon common jennies.

2d Machine. A feeding-cloth similar to that just described, and a pair of toothed, or sometimes fluted rollers, fed the cotton forward to a cylinder, covered all over with pikes or teeth, which produced an effect nearly similar to the comb; but the motion being circular, the machine, of course, was more simple and durable, and also, by its centrifugal force, served better to open the cotton. A grating helped to separate the motes. This machine was also sometimes called a devil, sometimes a picker.

It also, however, was evidently very imperfect, for which reason we think it unnecessary to describe it further.

3d Machine. In the "Repertory of Arts" may be seen a description of what is called a batting machine, which imitates remarkably well the motion of the rods used in batting by hand; but most of the motions of this machine being violent and suddenly reciprocating, it has a constant and rapid tendency to produce its own destruction. And however well it might answer in a cotton mill, where skilful mechanics are always at hand, it would soon become useless in the hands of common field labourers.

4th Machine. Another mode of cleaning cotton by machinery has been attended with a very considerable degree of success.

In appearance it somewhat resembles the second machine, having cylinders with teeth; but, in reality, it acts on quite different principles. The second machine operates principally by *tearing* the cotton from the feeding rollers; this by having it *laid on* the cylinders; and it produces its effects by the centrifugal force.

It was at Manchester, in the year 1797, that the then managing partner of the Rothsay Spinning Company saw a machine somewhat upon the construction above alluded to. It put on so fair an appearance, that he was induced to order one of them. The late Mr John Barton of Shudehill, Manchester, perhaps the most experienced cotton spinner at that time in England, was so obliging as to take charge of the making of it, and to try it in his mill previously to sending it off for Scotland. About the same time, he also ordered one of these machines for Mr White of the Culcreuch cotton works.

After getting the machines, Mr White, as well as the manager of the Rothsay works, was greatly disappointed; the grating was then made of wire, and they found it impossible to keep it from choking. Another evil was also, that the one cylinder *tore the cotton from the other.* It was rendered ropy, and was very much injured. These unpleasant circumstances gave them much uneasiness; but they persevered in their trials, and kept up a constant correspondence as to the results.

They found that a great improvement was made by raising the tops between the cylinders nearly to a straight line, and depressing the grating immediately below that part of the tops; and by allowing the front cylinder to throw the cotton on the back cylinder, instead of the back cylinder tearing it, by the back cylinder pulling it from the front cylinder.

About the same time, Mr White was so fortunate as to invent a new kind of grating of tin-plate, which

Cotton.

completely obviated all former objections to the grating.

These improvements were soon afterwards adopted at Manchester, and at some mills in Scotland.

It, however, occurred to the Rothsay manager, that an enlargement of the cylinders would be an improvement, by giving a greater extent for grating, as well as a greater space to throw the cotton by the centrifugal force. He accordingly had one made at Rothsay, with cylinders 5 feet in diameter, which fully answered his expectations. The cylinders of the machine which came from Manchester, were only, we think, about $3\frac{1}{2}$ or 4 feet diameter.

Machines, somewhat on the same principle, have been tried with the addition of fanners, the better to open the cotton, and to prepare it for carding; but we have not seen any that, upon the whole, answered so well as that which we have just described.

One of them was afterwards made for the Adelphi cotton works, Glasgow; and is still used for the whole of the cotton in that mill. It has been used for yarn as fine as 130 hanks per lb.; and takes out at an average about one oz of motes per lb. from the cotton.

From the rapid motion of the cotton over the grating, it is not only cleared of the gins, but by driving out all the dust, it greatly improved the colour of the cotton, which afterwards, before going to the cards, receives a slight hand picking, which takes out about a quarter of an ounce. The cylinders move at the rate of 242 revolutions per minute.

The cotton is commonly put twice through the machine, and it finishes about 140 lbs. in 7 hours; but this machine being only 22 inches wide, it is evident that, were it made wider, it would do a proportionate additional quantity of work.

It may also be proper to mention, that, at Rothsay, satisfactory experiments were made, the result of which was, that it did not at all injure the staple of the cotton.

Equal quantities of the same cotton were taken; one quantity was picked carefully by hand, the other was put a great number of times through the picking machine, and both were afterwards spun on the same frame into water twist. The number of threads of each kind which broke were carefully noted, and it was found, that the cotton which had been put through the machine, was as little liable to break as what had been done by hand,—a proof that the staple was not at all broken.

A gentleman from Demerary lately ordered some roller gins from Glasgow, upon a construction which promises to be a great improvement upon that machine, and will probably allow it to work at a much greater velocity than could hitherto been done, without injuring the cotton.

Description of the Roller Gin.

Description of the roller gin. Plate CCXII. Fig. 1.

The drawing, Fig. 1, Plate CCXII. represents the roller gin. The same letters refer to the same part on all the Figures. AB, CD, represents a pair of fluted rollers, commonly made of hard wood. They receive their motion from the foot by means of the cranks E, F, and the fly wheels G, H, somewhat in the same way as the common spinning wheel or foot turning lathe.

The negroe, who drives the machine, spreads the cotton on the cotton board. It is drawn in between the rollers, which serve to press out the seeds, and separate them from the cotton.

The seeds drop into the box I, and the cotton is delivered behind, and falls down the inclined board KL, thus cleared from the gins or seeds.

Description of the Saw Gin.

Description of the saw gin. Plate CCXII. Fig. 2.

ABCD is a roller about 9 inches diameter, which revolves in the direction marked by the arrow ↶. This cylinder consists of a number of circular saws S, S, S, &c. separated from each other by pieces of wood nearly one inch and a half in thickness.

Above the cylinder is placed a kind of hopper EFGH, into which the attendants throw the cotton, which falls upon a grating, up through which a small part of the saws projects.

The teeth of the saws lay hold of the wool, and pull it through the grating, whilst the seeds are by that means separated, and roll down the inclined surface of the grating, escaping by the spout IK. M is a cylindrical brush placed below the grating, which brush revolves, and by its motion serves to clear the teeth of the saws, and to throw the cotton clear of the cylinder, in the state in which it is ready to be packed for the home market.

Description of the Centrifugal Cotton Picker.

Description of the centrifugal cotton picker. Plate CCXII. Fig. 3.

The cotton is spread on the feeding cloth AB, which conducts it to the feeding rollers E, F.

The feeding rollers lay the cotton on the teeth of the front cylinder GH, and its centrifugal force strikes it against the tops I, K, and throws it upon the back cylinder MN.

The back cylinder moving with the same velocity, 242 revolutions per minute, acts on the tops in a similar manner, and conveys the cotton along part of the grating OPQRST, until it be laid hold of again by the front cylinder, and delivered into the receptacle UXYZ below the feeding frame.

In passing over the grating with such rapidity, the dust and gin are forced through the openings. From this circumstance, the machine not only takes out the gin, but greatly improves the colour of the cotton.

Description of an Improved Batting Machine.

Description of an improved batting machine.

A very considerable improvement has been recently made on the batting machine, with an account of which we shall conclude this part of the article. The idea of this improvement was taken from the thrashing mill. The cotton is fed through rollers, and struck by scutchers moving at a great velocity, which operation opens the cotton; at the same time it is blown by fanners, which serve further to open it, and to separate the lighter and finer parts, while the gin or seeds, sand, &c. are driven or fall through a harp or grating made of wire.

Plate CCXII. Fig. 4.

The cotton, as taken from the bag, is spread on the feeding-cloth AB, which conveys it forward to the feeding rollers. CD, EF are the scutchers, which, moving at a great velocity in the direction expressed by the arrow, strike and open the cotton as it is fed in by the rollers, while a strong current of air, produced by the motion of the fanners GHI, acts upon it. The gins, sand, &c. are driven through the circular harp LM, and fall on the angular harp NO. QR is a long harp or grating, which is level, and through which any remaining lumps or gins pass, while the cotton is blown forward to a small apartment or closet, from which it is from time to time removed. For fine spinning it is then ready to be picked by hand to take out any remaining moats, but for ordinary spinning it is taken immediately from the batting machine to the carding engine.

This improved batting machine not only saves much labour and expense, but from the manner in which the cotton is enclosed during the operation, much dust, films, &c. is prevented from escaping, which, as the process was formerly conducted, was most prejudicial to health.

The scutcher is 14 inches diameter, and makes from 1200 to 1400 revolutions per minute. The feeding rollers, one and three-fourth inches in diameter, go one revolution for 60 of scutchers. The fanners 22 inches diameter, same speed as the scutchers. The circular harp, under the scutchers, is one inch distant in the wires; all the other harps have their wires about three-eighths of an inch distant from each other. (O)

COTTON SPINNING.

Introduction.

The rapid progress of the cotton manufacture is unparalleled in the annals of trade. "In the year 1765, cotton, as an article of commerce, was scarcely known in this country."* "In 1782, the whole produce of the cotton manufacture did not exceed two millions sterling."†

"In 1801, the import of cotton wool into Britain was 42 millions of lbs. and the estimated value of the cotton manufacture 15 millions sterling. Such was the rapid increase of this trade to the end of the year 1801."‡

"Although in 1788 there were only 114 water mills in England, and nineteen in Scotland, yet the gross return from the raw material and labour exceeded seven millions sterling. It was estimated, that those establishments, when in full work, gave employment to 110,000 persons; that in all the subsequent stages of the manufacture, the number employed was estimated at 240,000, making an aggregate of 350,000 persons; and the quantity of raw material applied to the different branches of the manufacture, was computed at 22,600,000 lbs. But since the year 1788, the cotton manufacture has increased at least a three or four-fold ratio; the quantity of cotton manufacture being probably 80,000,000 lbs., the number of persons employed in all the branches about one million, and the gross value of the goods made above £20,000,000." §

The progress of the cotton manufacture, and its effects upon foreign traffic, as far as relates to Scotland, may be illustrated by the following statement of the imports of cotton into the Clyde at different periods:

	Bags.	lbs.
In 1775, there were imported	508 =	137,160
In 1790, ...	6509 =	1,757,504
And the average of six years, from 1804 to 1810, .	31,364 =	8,468,832
In 1812, ...	43,080 packages. ‖	

Thus we see, that little more than half a century has elapsed since the manufacture of cotton was scarcely

In order to explain and to contrast the effects of British mechanism with the simple labour of India, it is proper to explain the relative productive power of each, and the cost of cotton yarns, produced by each; comprehending that range of fineness, chiefly required for the eastern fabrics.

The quantity of mule spindles in Great Britain, appears, by actual survey, to be

4,200,000, Producing a quantity of cotton yarn, at least equal to that which can be spun in the same time by 4,200,000 persons in India; the wages of which are supposed at 2d. per day. In Britain

70,000 Persons would produce the same effect by machinery, at 20d. per day; consequently

1 Person in Britain is equal to

20 In India; but, in consequence of a more expensive apparatus, and various contingencies, it may be stated, that

1 Person is equal to 40 in India.

40 Multiplied by 2, is equal to 6s. 8d., which is the value of labour for spinning in India, to correspond with that of one person in Britain, or as 6s. 8d. to 1s, 8d.

Cotton Spinning.

known in this country. From this state of comparative insignificance, it has burst forth to be one of the most splendid branches of our national industry. In the following part of this article, we shall endeavour to trace the progress of an important department of this manufacture, (viz. the spinning,) and the causes which have contributed to raise it to its present state of importance.

HISTORY.

History.

The distaff and spindle appear to have been used for the purpose of spinning, by nations of the most remote antiquity; and it is worthy of observation, that, in all the countries which have been discovered by navigators for the last three centuries, these simple implements have been employed for the purpose of making yarn; and such is the mode still practised in India. Hence it has been inferred, that the same wants lead to the same means of relief. The use of the needle too, in all the above cases, is cited as a further proof of that opinion; and Pagan nations, unable to trace such useful contrivances to their true origin, attribute their invention to some one of their false deities. This simple machinery for spinning, was, in Britain, long ago nearly superseded by the well known domestic machine denominated the *one-thread wheel*. It continued in common use until about the middle of the last century, when the increase of the manufacture of cotton occasioned so great a demand for yarn, that a pause would naturally have ensued, and beyond which there could have been no advance, but with the slow and gradual increase of population. But as the demand for cotton goods increased, various contrivances were thought of for expediting the manufacture, and several attempts were made, but all with equal want of success, until the invention of the Jenny in 1767, by Richard Hargreaves, a weaver in Lancashire, a plain industrious man, but illiterate, and possessed of little mechanical skill. The invention is said to have been suggested by the accident of a spinning wheel being overturned, and seeing it continue in motion after its fall. Among his first attempts, he made a very rude machine containing 8 spindles, turned by bands from an horizontal wheel.

The jenny invented.

The popular prejudice being raised against him, he found it prudent to leave Lancashire, but he had previously constructed machines of from 12 to 16 spindles. He removed to Nottingham, and after assisting various persons in the construction of machinery, he died in poverty, ill requited by his employers, and little known to the country which reaped the important fruits of his discovery. While employed in Nottingham, a serious affray took place in opposition to the new machines, in which Hargreaves and others are said to have been severely wounded.

Various alterations were afterwards made on the original machine; the vertical was substituted for the horizontal wheel, which, with other improvements, rendered the jenny a much more commodious machine. It was enlarged in its dimensions, and made to contain twenty, thirty, and even eighty spindles; and although at first it met with determined opposition, yet it soon spread rapidly over the country; and it is worthy of observation, that those who were most strenuous in opposing it, were the first to avail themselves of its advantages.

Cotton Spinning.

Another improvement is also ascribed to Hargreaves. He is said to have been the inventor of *stock-cards*, which succeeded the hand-cards. This improvement enabled one person to perform double the work, and with more ease than could be done by the former method. This improved mode of carding consisted in applying several cards to the same stock, and suspending the upper stock by a rope passing over a pulley, having a counterpoise to the otherwise unmanageable weight of the stock.

Stock cards.

This contrivance was soon succeeded by the cylinder-cards, or carding engine. It seems uncertain who was the inventor of this valuable machine; but it is known, that the father of the present Sir Robert Peel was among the first who employed it, having, at Blackburn, as early as the year 1762, assisted by Hargreaves, erected a carding engine with cylinders; but this machine had no contrivance for stripping off the carded cotton. This operation was performed by women with hand-cards.

Carding engine.

We come now to mention by far the most important improvement in cotton-spinning; and indeed, if the steam-engine be excepted, we do not know any mechanical invention that has made such an amazing addition to the activity, industry, and opulence of this island, as the invention of Mr Arkwright for spinning by water, where dead matter is made successfully to imitate the human finger, directed by the unceasing attention of the eye.

Arkwright's water spinning frame.

Soon after the invention of the jenny in 1769, Arkwright brought forward his improvement in spinning, in which he had long been laboriously engaged.

Of this distinguished character we have already given some account, (see Arkwright.) We may, however, mention here, that he was born in an humble rank, and the youngest of thirteen children, and was a native of Preston, in Lancashire. The difficulties with which he had to combat, before he could bring his machine into use, even after its construction was sufficiently perfect to demonstrate its value, would have disheartened any but the most ardent genius. Some doubts have been entertained of the justice of his claims to the first ideas of the improvement; but it is beyond all doubt, that he was the first person who rendered it of practical utility, and by that means he was raised from one of the most humble occupations in society to affluence and fame.

The important and essential part of his improvement, by which the form of the cotton is so wonderfully changed, and to which all the rest of the process is subservient, and Arkwright's chief invention, is the *substitution* of machinery for the human finger. This machinery consisted of a peculiar application of rollers. He is said to have taken the idea of this improvement from accidentally seeing a red-hot iron bar elongated, by being passed between rollers; and although there be no strict mechanical analogy between this process and that of his

It is therefore evident, that one spinner by machinery in Britain will produce yarn at one-fourth of the price that it costs for the same quantity of workmanship in India, supposing the wages of the former to be 1s. 8d. and the latter to be 2d. per day; and reckoning the mean price of cotton wool, in Britain, at 2s. 6d. and in India at 5d., the cost of labour and materials united, would be less, upon an average, than one half; we shall consequently be able to meet competition in the eastern markets, either in yarns or in cloth, of which they form the principle constituent value.

Very important discoveries and improvements have, doubtless, been made in weaving, dyeing, printing, and bleaching; and particularly for certain operations and descriptions of cloth; but taken in the gross, the amount will bear but an inferior proportion to the economy introduced by spinning, upon which both invention and exertion have been upon the rack for the last thirty years, and a real capital vested in building and machinery of from eight to ten millions sterling.

Cotton Spinning.

improvement in spinning, yet from this hint being pursued arose, if we are rightly informed, an invention which, in its consequences, as a source of individual and national wealth, is without example.

Arkwright's water-spinning frame.

As already noticed, the effect of Mr Arkwright's application of rollers was precisely the same operation which the spinner performs with the finger and thumb; and the adaptation of this simple and beautiful contrivance to the spindle and fly of the common domestic flax-wheel produced what is called the *water-spinning frame,* the machine for which Mr Arkwright obtained his *first* patent, and on which was founded all his subsequent improvements.

But a considerable time elapsed before this patent was obtained, his circumstances not permitting him to commence business on his own account, and no person seemed willing to hazard capital in the undertaking. At length, however, he was so fortunate, as to secure the co-operation of some persons, who had sufficient discernment to see the merit of the invention, and he consequently obtained his first patent for spinning *by means of rollers* in the year 1769. His first mill was erected at Nottingham. It was worked by horses, but this mode of working being found too expensive, a larger mill driven by water was erected in 1771, at Cromford in Derbyshire. At this place he principally resided during the remainder of his life. In the year 1772, his patent right was contested; but he obtained a verdict in his favour, and enjoyed the patent to the end of its term.

The essential part of Mr Arkwright's invention being entirely new, he applied it with the happiest success in various forms, in several of the stages of the *preparation* of the raw material for the spinning; and soon after the erection of his mill at Cromford, he made many ingenious improvements in the mode of preparing the cotton; for all of which inventions he obtained a patent in 1775. But after reiterated contests with rival manufacturers in the year 1785, the Court of King's Bench cancelled this patent, on the ground of his not being the original inventor.

The contests above alluded to related chiefly to the operation of *carding,* which was now brought to a state of great perfection. We already mentioned, that the cotton was at first stripped from Mr Peel's machine by hand. Afterwards, this operation was performed by a roller, having tin plates like the floats of a water-wheel. This was, however, a very rude method. Mr Arkwright substituted a comb of metal, moved rapidly in a perpendicular direction by a crank; and in order to produce in the finishing carding a *continued fleece,* he introduced narrow cards, termed fillets, wound, in a spiral form, round one of the cylinders of the machine.

This operation of combing off the cotton in a continued fleece, and gradually contracting it into a narrow ribband, flattened between rollers, and delivered in the form of a uniform carding, is allowed to be one of the most striking and beautiful in the whole process of cotton-spinning. Mr Arkwright's right to the invention of the crank and comb was disputed in the last hearing of his cause. His claim, however, to the spiral cards, which produce the *continued carding,* has never been disputed.

That all these inventions and improvements should have been the production of an individual without education, or any previous mechanical knowledge or experience, is most extraordinary. Yet he was engaged at the same time in many other concerns, arising from the peculiarity of his circumstances. While he was extending the business on a large scale, he was introducing into every department of it a system of order and cleanliness, till then unknown in any manufacture. And all these exertions, too, were made when he was suffering under an oppressive disorder, which at last terminated his life.

Having now brought our history of Mr Arkwright's improvements to a conclusion, it may be proper to mention, that, notwithstanding the measures that were formerly taken to convince the labouring class of their folly and injustice in opposing improvements, a third and more numerous mob assembled in 1779, by which all the machinery for spinning by power, and all the jennies above a certain size, within eight or ten miles of Blackburn, were destroyed. These and similar disturbances in other parts of the country retarded, but could not stop the progress of the manufacture.

Water-twist.

The yarn produced by Sir Richard Arkwright's system of spinning is denominated *water-twist;* and from its strength and wiry smoothness, was found peculiarly applicable to the longitudinal part of webs, called *warp,* whilst the yarn produced by the jenny of Hargreaves, from its woolly fulness and softness, was better adapted for the *woof* or *weft* of coarse goods. These systems of Hargreaves and of Arkwright, for some years after their introduction, produced (with the exception of the small quantity that would be spun on the one-thread wheel) the whole of the cotton, twist and weft, used in the kingdom. But during the term of Sir Richard Arkwright's first patent, a *third* system of spinning by machines called *mules* was invented, which has almost entirely superseded that of Hargreaves, and has even in part superseded the mode of spinning invented by Arkwright. We say *spinning,* because his mode of *preparation* (which expression includes carding, *drawing,* and *roving*) is retained in *mule spinning,* and indeed the essential part of his system, *the rollers producing the effect of the finger and thumb.* On the application of this part of the system to the jenny of Hargreaves, the merits of the third *mode* of spinning (by the mule) in a great measure depends. Its utility has, however, been very great, and the variety of *qualities* of yarn produced by it is much greater than is possible by any of the former modes, at the same time that much finer yarn has been spun in this way than was before practicable. As an instance, we may mention that one pound of fine cotton has been spun on the mule into 350 hanks, each hank measuring 840 yards, and forming together a thread 167 miles in length.

Spinning machines called mules invented.

The *mule* seems to have taken its name from having been the offspring of the two machines in use at the time of its invention. This compound machine was invented by Mr Samuel Crompton, formerly of Hall in the wood near Bolton, in Lancashire, a person of very great ingenuity, and to whom the public is indebted for many other valuable improvements in the cotton manufacture. He also seems to have laboured under many disadvantages in his outset, as may be inferred from the following extract of a letter from him to the writer of this article: " In regard to the mule, the date of its being first completed was in the year 1779. At the end of the following year, I was under the necessity of making it public or destroying it, as it was not in my power to keep it and work it, and to destroy it was too painful a task, having been $4\frac{1}{2}$ years at least, wherein every moment of time and power of mind, as well as expence which my other employ would permit, were devoted

Cotton Spinning.

to this one end, the having good yarn to weave, so that destroy it I could not." We have the satisfaction to observe, that parliament lately voted him a sum of money as a reward for his invention.

The mule was for many years worked by hand only, the variety of movements rendering it difficult to accomplish the working of it by the power of water or of steam sufficiently simple to be of common use.

Working mules by power.

Mr William Kelly at Lanark in Scotland, early obtained a patent for a mode of working this machine by power; but it was not until a considerable time afterwards that power was generally adopted. The plans which were tried were various, and the improvement progressive. One happy consequence of this improvement has been experienced,—the spinners are found now to enjoy better health than they did when they had to labour hard, while they breathed in warm and confined apartments, and on the whole, the working of mules by power may be considered as an epoch in the history of the cotton manufacture.

Throstle.

Of late years a modification of the water-spinning-frame, called the *throstle*, has come much into use for spinning *twist*. Its principles are, however, exactly the same as Arkwright's machine. Although the construction be somewhat more simple, and the cost less, yet it is in other respects not so perfect; and as we have elsewhere observed, (See Arkwright,) it is remarkable that since the time of Arkwright, no real improvement has been made in the construction of the water-spinning-frame.

Cotton spinning by machinery introduced into Scotland.

Arkwright's mechanism for preparing and spinning cotton had not been long in use in England, when it began to attract the attention of the traders in Scotland, who soon attempted to draw what was then, to many, a most lucrative branch of manufacture to Scotland. But it is difficult to plant a manufacture in a new country, even where there is no secret in the process; and the difficulty was still greater in this instance, where pains were taken to keep the business involved in mystery. Many who had been employed in the works of Arkwright left his service, pretending to a knowledge of the business, which they were very far from possessing, and those men were for a time eagerly sought after by new adventurers in the manufacture in both kingdoms; but in most cases these adventurers were no gainers by the acquisition. This may be easily conceived when we consider how very little a great proportion of the people now employed in our cotton mills know, and how much less they can communicate, of the construction of the machinery, or the general system of the business. If such be the case at present, what must it have been at the period of which we are speaking, and among men very deficient in the simplest branches of education?

Cotton mills erected in Scotland.

Notwithstanding these obstructions, however, several establishments were soon formed in Scotland. We have reason to believe, that the first cotton spun by water in this kingdom, was in the island of Bute, in what had been a lint mill, and was afterwards for some time the corn mill of Rothsay. But this was only by way of trial, and before the completion of the larger cotton mill. Nearly about the same period, cotton was spun at Pennycuick mills near Edinburgh, and also about the same time, viz. in the year 1780, the mill of Barrhead, in the parish of Neilston, was completed. Soon afterwards that of Bushby, in the parish of Mearns, and in the year 1782, a large mill of six stories was erected at Johnston in the parish of Paisley.* This was the first extensive establishment in Renfrewshire, and there is reason to think it was the first in Scotland which was productive of much profit to the proprietors. It was originally managed by people from England, but they proved of the description to which we have above alluded, and the proprietors were in all probability indebted to the discernment, perseverance, and mechanical genius of Mr Robert Burns, a native of Paisley, for rescuing the concern from ruin, and rendering the business a source of affluence.

We have already spoken (article Arkwright) of the establishment of Mr Dale's extensive works at Lanark, in which concern Mr Arkwright himself was for a time a partner. It is needless to enter further into the detail; suffice it to say, that in Renfrewshire alone, the number of cotton mills are now about 41, containing 237,000 mule spindles and 28,500 spindles for water-twist.† Besides the many extensive establishments in Lanarkshire, (which includes Glasgow,) and others in the counties of Ayr, Perth, and Aberdeen.

The working of mules *by power* seems to have originated in Scotland; and it is ascertained that one great desideratum in cotton-spinning, a machine for cleaning and opening the raw material, was first brought to its present degree of perfection in that part of the island. This is the most important improvement that has been made in the process for many years; and, we are informed, was first accomplished at Johnston, in the works of Messrs G. Houston and company, by Mr Peter Cooper, millwright.

GENERAL DESCRIPTION.

General description.

Having said thus much respecting the history of cotton-spinning, it will now be proper to give some description of the operations which cotton undergoes in its passage from the raw material to the state of yarn. It would require volumes to describe these operations in a complete manner, but our limits will only permit such an outline as may enable the reader to form some general idea of the subject.

The modes of producing yarn in the manufacture of cotton, as now conducted, may be considered as dividing into the following branches.

1. Jenny Spinning.
2. Water Spinning.
3. Mule Spinning.

The mechanical operations which cotton undergoes in these three modes of spinning are various, according to the purpose to which the yarn is to be applied. These operations may be resolved into the following elements: 1st, *Batting*. 2d, *Carding*. 3d, *Stretching*. 4th, *Plying*, (or as it is sometimes, though perhaps improperly called,) *doubling*. 5th, *Drawing*, and 6th, *Twisting*.

Jenny spinning employs only the 1st, 2d, 3d, and 6th, of these elementary processes. *Water spinning* employs them all excepting the 3d, (stretching,) while *mule spinning* employs the whole six.

These elementary processes will be better illustrated as they occur, than by attempting to give in this place abstract definitions of them, we shall therefore proceed to consider the first of the above stated branches of spinning.

* See Wilson's *Agricultural Report of Renfrewshire*, p. 249.   † Ibid.

Cotton Spinning.

I. Of Jenny Spinning.

Jenny spinning.

The jenny, in its manner of action, resembles the ancient spinning with the distaff and spindle, but is so contrived that one person works a number of spindles at once. We have seen that it was the earliest improvement on spinning after the *one-thread wheel,* and was the invention of Richard Hargreaves, weaver in Lancashire, in the year 1767.

The jenny continued long in use for producing *woof* or *weft* after the introduction of Arkwright's mode of spinning, which last was employed in producing *warps.* But as the *jenny* is now almost entirely superseded by the *mule,* we shall be very brief in our description of the machinery and operations, which come under this branch of spinning.

Batting. In another place, (see page 279, &c.), we have spoken of the various modes of cleaning cotton, which come under the *elementary process* denominated *batting.* For *jenny spinning,* it is next soaped, in order to make it more easily stretched in the roving and spinning. The soaping is performed by immersing the cotton in a solution of soap in water. It is next put into a screw press, and afterwards dried in a stove.

Carding.

Carding. Carding is the *second elementary process.* The card is a kind of brush made with wire, stuck through a sheet of leather, the wires being inclined one way at a certain angle. By this process the cotton is further opened, and the knotty parts disentangled, so as to form the whole into a uniform fleece.

We already mentioned that hand cards first, and stock cards afterwards, were employed before the invention of the cylinder cards. See Card *Manufacture.*

The carding machine, which has long been employed in this branch of spinning, consists of two larger and two smaller cylinders, and a number of rollers all covered with sheets or fillets of leather, containing the card teeth, similar to those of common hand cards. The larger cylinders move with considerable velocity; and the smallest ones go slowest.

Feeding-cloth. At one end of the machine is what is called the *feeding-cloth,* which, by means of rollers and pullies, receives a constant uniform motion. The cotton is weighed in equal portions, and spread on equal lengths marked on the cloth, which, by its motion, conducts the cotton to the first large cylinder, the teeth of which immediately lay hold of it. It is again taken off and laid on again by the rollers called *urchins.* It proceeds to the first small cylinder, and so on, till it passes to the last small cylinder called the *doffer.* The *doffer* is cleared by means of a steel comb, which receives an alternate motion from a crank. This contrivance, as already mentioned, is one of the most ingenious in cotton-spinning, and which we shall afterwards more particularly describe. The little fleeces taken off by the comb fall in between a smooth cylinder, having several very small projections on its surface, and a fluted arc, which serves to form the fleeces into little rolls about the size of candles. These rolls fall in regular succession on a moving cloth similar to the *feeding-cloth,* and they are in that state ready to be conveyed to the next operation called the roving.

Roving or Stubbing.

Roving. The roving is performed on similar principles to the spinning jenny, on a machine called a billy, containing generally about 36 spindles, which are driven by means of bands from a cylinder, which receives its motion from a vertical fly wheel driven by hand at one end of the machine.

This machine has a feeding-cloth on the side next the carding engine. Children are employed to lift the rolls or *rowans* from the carding engine, and unite them on the *feeding-cloth,* so as to form as many rolls as there are spindles in the machine. In order to *stretch* out these rolls, after a certain number of revolutions of a roller, the feeding-cloth stops, and the rolls are laid hold of by two horizontal pieces of wood the breadth of the machine, (which we may call the clasps,) which, when pressed together, clasp the rolls in imitation of the finger and thumb on the old *one-spindle* machine; from these pieces of wood the rolls pass to the spindles, which are disposed on a moveable carriage, which is made to recede, and by that means extends the rolls, reducing them to the proper size of the roving. This is the third elementary operation which we have denominated *stretching,* and the first time that it occurs. It is carefully to be distinguished from the fifth, viz. *drawing,* which is performed by means of rollers, but which does not occur in jenny spinning. This extended roving receiving a small degree of twine, is built on the spindles in the form of a cone by means of levers and wires, in doing which the carriage is returned to its former situation. These cones are called *cops,* and when made as large as the distances of the spindles admit, are taken off the spindles, and are ready to be spun on the jenny. The *twist,* which the roving here receives, is the first occurrence of the sixth elementary process, which is obviously essential to every mode of spinning. Stretching. Twisting.

The Jenny.

The jenny. The *jenny* is a machine, similar in its *operation* to the *roving billy,* but differs from it in *construction* in this respect, that the *clasp* is attached to the carriage, while the spindles are disposed in the rails of the frame which remain at rest. The drawing out of the clasp stretches the roves so as to reduce them into the size proper for the yarn; at the same time the spindles twine it. During the return of the carriage, the yarn is built on the spindles by levers and wires, and formed like the rovings into cops. It is wrought with the hand by one grown up person, assisted by a boy or girl, called a *piecer,* in order to mend such threads as break. The yarn, when taken off the spindles, is sometimes reeled, but more frequently given to the weaver in cops, who has it wound on the *bobbins* or *pirns* preparatory to being placed in the shuttle.

Common jenny yarn is now but little used, excepting for the woof or weft of calicoes. For this purpose, however, it is more esteemed than what is spun on mules, as it gives the cloth a more full and rich appearance.

II. Of Water Spinning.

Of Water spinning. The second method of spinning is denominated *water-spinning.* It received this name from being the first spinning done by a water wheel, and was the invention of Sir R. Arkwright.

Carding.

Carding. After the cotton is picked, the usual process is to card it first by a carding machine, called a *breaker,* and a second time on another, called a *finisher.*

The *breaker* consists of a larger and smaller cylinder.

The larger, or *main cylinder*, is covered with sheet cards, and moves at a considerable velocity; the lesser, or *doffing cylinder*, is covered with a spiral fillet of card wound round it, and moves slowly. These cylinders revolve in opposite directions, and nearly in contact with each other. Over the main cylinder is a kind of arch covered with cards at rest, called the *top cards*. The cotton is fed by means of rollers into the main cylinder. The main cylinder lays it on the *doffing* cylinder, from which it is combed, (as already mentioned of the carding for jenny spinning,) and in an uniform fleece is wound round a cylinder, or sometimes, instead of it, on a perpetual cloth. After this cylinder or cloth has made a certain number of revolutions, and thereby plying or doubling, (the fourth elementary process,) the cotton is broken off, and is in that state (called a lap) ready to be carried to the *finisher*.

Plying.

The *finisher* is similar to the *breaker*, only that the fleece, instead of forming a *lap*, is gradually brought into a narrow *band* or *sliver*, and is compressed by a pair of rollers, which deliver it into a tin can, which is afterwards removed to the drawing frame.

The Drawing-frame.

Drawing frame.

In this machine, *drawing*, (the fifth elementary process,) first occurs. Drawing is a curious contrivance, and is the ground work or principle of Arkwright's invention, for it is used in the *roving* and *spinning* as well as in the *drawing frame*. It is an imitation of what is done by the finger and thumb in spinning by hand, and is performed by means of two pair of rollers. The upper roller of the first pair is covered with leather, which being an elastic substance, is pressed, by means of a spring or weight. The lower roller, made of metal, is fluted, in order to keep a firm hold of the fibres of the cotton. Another similar pair of rollers are placed near to those we have been describing. The second pair, moving at a greater velocity, pull the fibres of the cotton from the first pair of rollers. If the surface of the last pair move at twice or thrice the velocity of the first pair, the cotton will be drawn twice or thrice finer than it was. This relative velocity is called the *draught* of the machine. This mechanism being understood, it will be easy to conceive the nature of the operation of the *drawing frame*. Several of the narrow ribbands or *slivers* from the cards, (or as they are sometimes termed *card ends*) by being passed through a system of rollers, are thereby reduced in size. By means of a detached single pair of rollers, the reduced ribbands are united into one sliver.

These operations of drawing and plying serve to equalize the body of cotton, and to bring its fibres more on end, which, in the *card-ends*, were crossed in all directions. These slivers are again combined and drawn out, so that one *sliver* of the finisher drawing contains many plies of card-ends. Hitherto the cotton has got no twist, but is received into moveable tin cans or canisters, similar to those used for receiving the cotton from the cards; sometimes, however, it does receive a small degree of twist in the finishing drawing.

Roving.

Roving.

The roving is a process similar to the drawing, only that it always communicates a degree of twist to the cotton. The roves are wound up on bobbins, and are then ready to be spun. The operation of *winding* is in some cases performed by hand, and in others by power.

Spinning.

Spinning.

The bobbins containing the rove are placed on the back part of the spinning-frame. The spinning is little more than a repetition of the process gone through in making the rovings.

The *spinning-frame* contains rollers similar to those of the *drawing* and roving frames, which serve to extend the rove, and reduce it to the required fineness; at the same time it is twisted by means of a spindle, but of a different kind from that of the common jenny.

Previously to the year 1767, spinning was performed on the domestic one-thread wheel, of which there were two kinds. The *first*, which had a simple spindle, required the material to be previously carded; and, as we have seen, the common jenny was founded upon this simple machine.

The *second* was the flax-wheel, which was used for other substances, that, from their nature, but more particularly from the length of staple, did not admit of carding, but were prepared by an operation resembling *combing*. The spindle of this machine had a bobbin and fly, which served to wind up the yarn as fast as it was spun. This last kind of spindle is that which was adopted by Arkwright in his mode of spinning. When the bobbins are full, they are taken off the spindles in order to be reeled.

The Throstle.

The throstle.

A machine called the throstle has of late years come much into use for spinning water-twist. Its principles are the same as those of the water-frame, but it has fewer parts. In the water-frame, every *head*, as it is called, (of four or six spindles) may be stopped separately; whereas, in the throstle, the whole rollers and spindles on each side of the machine are connected.

Reeling.

Reeling.

The reeling is performed on a machine consisting of six wooden rails parallel to the axis, which winds a considerable number of threads at once from the bobbins. It is one yard and a half in circumference, and is of such a length as to give room for the hanks without danger of the threads getting foul of each other. At one end of the axis is wheel-work, constructed to strike a check at every 80 revolutions of the reel. These 80 revolutions form a *ley*, or *rap*, of 120 yards in length, and seven of these *leys* constitute a hank, which measures 840 yards.

The size of yarn is denominated from the number of such hanks of 840 yards as will weigh one pound. Thus what is called yarn No. 60, contains 60 hanks in each pound weight. This measure is now in use for cotton yarn in Scotland as well as in England; but the old Scotch reel is different, 18 English hanks being reckoned nearly equal to a Scotch spynal.

The size of the yarn is ascertained by weighing the hanks on an instrument called a *quadrant*, and each size is put up separately in bundles of 10 pounds weight. These bundles, by means of the *bundling press*, are neatly formed into cubical packages, which being put up in paper are ready for the market.

Water twist is generally spun hard, and in that case is used for purposes requiring much strength, such as the warps of fustains, calicoes, &c. A softer kind of *water twist*, which is very uniform and even in its thread,

Cotton Spinning.

is used, when doubled and slightly twined, for making stockings, and is denominated stocking yarn. The lower numbers are sometimes used single, and are called double-spun. Water twist is used of all sizes from No. 6. to No. 60.

III. Of Mule Spinning.

Of Mule spinning.

The spinning machine called the *mule*, most probably derived its name from partaking of the nature both of the *jenny* and of the *water-frame*. The invention of the mule may be considered as a new æra in the history of cotton spinning. The combination of the jenny with Sir R. Arkwright's invention of *drawing by rollers*, forms a method superior to both, at least for fine goods, and much finer yarn has been produced by the mule than is practicable by either of the other methods.

Preparation.

The *preparation* for mule spinning is the same, or similar to that for water spinning, only that, in order to reduce the rovings for fine yarn to a small enough size, the cotton generally passes through a machine called a *stretching frame*, which is constructed nearly like a *mule*, and which will be more easily explained after describing that machine. The rovings taken off the spindles of the *stretching frame* are formed into *cops*, and these rovings so formed are placed in the mule, in order to be spun.

The mule consists of a system of rollers similar to the *spinning-frame*, but coupled together instead of having every four or six threads in separate *heads*, by means of which the rove is drawn, and received on spindles revolving like those of the jenny. The carriage on which the spindles are disposed is moveable, and recedes from the rollers as the thread is delivered. After a certain quantity of the roving is thus given out by the rollers, they are stopped, but the carriage continues to recede a certain distance further, the spindles continuing in motion, and by that means stretches the thread still finer. This last part of the operation resembles the effect produced by the jenny. The building of the yarn on the spindles, in the form of cops, during the return of the carriage, is performed in a manner similar to the forming of the cops in the roving billy.

Mules are various in their number of spindles, but since they have been moved by power, 300 spindles in each is not uncommon. Two machines are usually attended by one man assisted by children.

The *stretching frame* will now be more easily understood. It is like a mule, but the spindles are placed at a greater distance from one another. But the name *stretching frame* seems improper, for it merely reduces the rove by *drawing* it by the rollers, for the carriage recedes at the same rate as the rollers deliver the roves without *stretching* it. The mule, we have seen, does *stretch* the thread after the rollers have ceased to move, and generally to a certain degree even during their motion.

Description of a New Diagonal Mule.

New diagonal mule.

The astonishing reduction of labour, which has been effected by the introduction and improvement of the various kinds of machinery for spinning cotton yarn, is certainly the primary cause of the incredible extension to which that manufacture has been carried; and the competition among those who have embarked in the business, added to the exclusion from foreign markets, may be regarded as the reasons of the corresponding reduction of the prices of all kinds of manufactured cotton goods.

Cotton Spinning.

New diagonal mule.

The principal difficulty which the spinning trade has now to contend with, is the very large capital which it is necessary to sink in buildings and machinery, before an establishment can be formed capable of contending in the market with those previously erected. To counteract this impediment, in some degree, is the object of the invention, or rather improvement, which is here suggested for the consideration of those interested, or who wish to interest themselves in this manufacture.

As the alteration from the established practice affects no principle, upon which the quality of cotton yarn *does* or *can* depend, there is no reason to hope that the article manufactured in this way will be improved, and as little cause to fear that it will be deteriorated by the change. A reduction of the amount of the sunk capital, necessary to put a certain number of spindles in motion, and to manufacture a certain quantity of cotton yarn, of a quality equal to what has been hitherto spun, are the only objects in contemplation.

The expence of erecting a mill or manufactory may be divided into three classes, upon each of which, it is demonstrable, that the use of machinery upon this plan would save much expence in the erection, the necessary repairing, and the working. These are,

1*st*, The expence of erecting suitable buildings to carry on the business.

2*dly*, That of procuring adequate power, whether water or steam, to put the machinery in motion.

And, 3*dly*, The expence of the machinery itself.

In order to establish these points to the satisfaction of our readers, especially those conversant with the business, it will be proper to describe the proposed machine, referring to Plate CCXII. for the illustration, and then to deduce, from the nature of its construction and operation, a proof of its capability of producing yarn equal to any now spun, with a great reduction on each of the three heads which have been premised. Plate CCXII.

Fig. 5. is a horizontal plan of the mule, of which the following are the particulars: Fig. 5.

The length from A to D, and from B to C, ought to be 10 or 12 inches more than that of a mule with a single row of spindles, supposing the length of draught to be the same, because the row of spindles, nearest to the guide H, can never be brought so nigh to the rollers by nearly a foot as in a common mule. The breadth for an equal number of spindles is taken at one-third of an ordinary mule, supposing 12 inches to be allowed for each dozen of spindles, which is very common, excepting for mules intended for coarse yarn, in which case 14 or 15 inches are generally allowed. From the smallness of the scale upon which the plan is laid down, every *third* spindle only is represented; so that each diagonal row of the spindle frame E ought to contain 12 spindles, or 13, if both extreme spindles are counted into one row. These spindles will be one inch asunder, and the whole mule, although only six feet wide between the frames, will contain 216 spindles, which, in the common mule, is estimated to be a large number, and requires 18 feet within the framing, at one inch asunder. The framing is bounded by ABCD; the diagonal spindle frame is at E; the rollers, which (if 12 inches between the couplings, will draw for three dozen of spindles each,) are at F; the frame which contains the *roves* or *rovings*, from which the yarn is to be spun, is at G. The guide

Cotton Spinning.

for directing the yarn in winding up and building, or forming the *cop*, is at H. The three pullies, for the single speed, the double speed, and disengaging the mule, are at I; the large wheel for driving the cylinder or drums, as the case may be, which turn the spindles, is at K. The smooth roads of iron, or, as they are usually termed, the *race roads*, upon which the carriage moves, are at LL; and the shaft, which moves the rollers until the delivery ceases, is at M.

Plate CCXII. Fig. 6.

Fig. 6. is a perspective view of the mule, as it would appear at the distance of 10 or 12 feet from the left hand front corner. The guide H, and the connecting shaft M, are omitted, because they would conceal other parts if introduced, and also because they are sufficiently laid down in Fig. 6; there being nothing materially different in their construction from the common mule, excepting that the arms of the guide are longer, in order that the directing wire may descend, without interruption, over all the diagonal rows of spindles. All the other letters of reference denote the same part in Fig. 6. that they do in Fig. 5. The upper, or leathered rollers, are also omitted, there being nothing peculiar about them.

We come now to the most essential and interesting part of this subject, namely, the comparison of this machine with those at present in use, and the immense saving of sunk capital of which it may be rendered productive. For the sake of perspicuity, we shall arrange this estimate under the three distinct heads, pointed out in the introductory part of this section.

1*st*, *The Expence of Building.*

Expence of building.

We have seen that, by placing the spindles only one inch asunder, a mule of 216 spindles will require a space of 18 feet, exclusive of what is occupied by the framing, and the space allotted for the driving pullies, and large twining or twisting wheel. If four feet be allowed for these, and only five feet more for passages round the machine, the breadth of the building (within the walls) must be 27 feet at least.

The breadth of this machine (containing an equal number of spindles) will be only six feet within the framing, to which, if we add the same allowance for framing and passages, we shall have 15 feet; and as only one passage is required in the middle, we have two sets of mules, with a middle passage of three feet, exactly in the same bounds as were required in the former case. Here, then, we have the number of spindles doubled in the same bounds; or, in other words, the saving upon the building amounts to 50 per cent. or one-half of the whole.

2*dly*, *The Expence of Power and Mill Work.*

Expence of power and mill work.

The saving of power will be found to be in a still greater ratio.

In the *first* place, we have only one-third part of the drawing rollers to move, and have, of course, only one-third of the weight, and one-third of the friction to overcome. We have, indeed, the same number of spindles; but as the house will contain two rows, and will be only one half of the length, the whole is brought more contiguous to the power, and one half of the weight, friction, and expence of the mill shafts will be saved; besides which, the engine will only require at most half the power, and consequently may be erected at less than half the expence, and wrought with less than half the fuel.

3*dly*, *Expence of Machinery.*

Expence of machinery.

The expence of the machinery may very fairly be estimated in the same way. Two-thirds in length of the cross-railing, carriage, rollers, &c. will be entirely saved; and from the short and compact shape of the mule, every part may be reduced in materials two-thirds, with greater strength than before; for the stress being as the length multiplied into the weight, and two-thirds of each being saved, the product will be in the ratio of 1 to 9, or nearly so, when compared with the former. For if the length be expressed by a, and the weight by b, the stress will be as $a\,b$; and if two-thirds are taken from each, the result will be $\frac{a}{3} \times \frac{b}{3}$ or $\frac{ab}{9}$. The weight and expence of the whole shafts may be reduced in a similar ratio, without any diminution of strength.

After having maturely weighed this plan during some years, and submitted it to the inspection of several extensive practical spinners, no objection whatever to its practicability has ever been stated; although it would have been very natural to expect that those, who have already embarked their property in establishments on the present plan, from which it could not be withdrawn, *under any contingency*, without an immense and ruinous loss, would be far from desirous to promote, or even sanction a plan, the very object of which is to enable others to compete with them at less than half the expence.

One objection, however, does exist, which, although it does not appear impossible, nor even very difficult to surmount, it ought to be candidly and explicitly stated, in order to guard the engineer, who may attempt to reduce this plan to practice at an early period, against what will prove his chief obstacle.

The diagonal form in which the spindles are placed, necessarily brings the threads much nearer to each other than by the common plan; and as some threads break at almost every draught, there is reason to apprehend, that the contiguity of the threads may, in this case, prove of some practical disadvantage. A fractured thread, especially after having received a considerable degree of twisting, has always a tendency to deviate from the straight line in which it was stretched, and to entangle itself with the adjacent threads. The nigher that the threads are brought to each other, this disadvantage must be the more increased, and consequently there certainly exists a danger, that, in this plan, one thread may frequently be the cause of breaking many, unless some means be resorted to, to keep them asunder. The tendency of a thread to deviate from the line in which it was stretched, it is presumable, must be in the ratio of the square of its length; for its utmost possible deviation would be 90° from its former position before the fracture. Hence we find that in spinning, if a thread gives way at an early period of the draught, when the spindles have receded but little from the rollers, it seldom if ever does the smallest injury to the contiguous threads; and we also find practically, that the greatest mischief is produced in twisting the threads at the end of a draught, when the yarn is at its greatest stretch, and when both the delivering rollers and the carriage have ceased to move. On this principle, the following

Cotton Spinning.

small addition, which is neither complex nor expensive, is suggested, as a mean of greatly reducing, if not entirely removing, this inconveniency.

Plate CCXII. Fig. 5.

Across the machine, under the threads, and sufficiently low not to interrupt the action of the guide, let there be one, two, or, if necessary, more shafts of wood, like that represented at N. At each end of this shaft, let there be a cross piece of iron, or strong wire, as at PP, and let these pass through sockets or eyes in the frame, so that N may slide freely to and from the rollers as required. Then, if a number of smooth wires or pins be driven or screwed into N diagonally, like the dots in the Figure, they will keep the yarn asunder, and prevent the inconvenience alluded to; N will follow the spindles, when drawing out, as far as is found convenient, where it may be stopped with a pin, by a small weight suspended over the pullies O, O, and the carriage returning will push N before it, so that no interruption can take place. Thus the threads may be kept asunder at as many points as are found convenient, with very little trouble or expence.

If it be found desirable that the threads should be farther asunder, without increasing the breadth of the machine, this also may be effected in another way. If the diagonal spindle frame E, instead of being horizontal, be sloped to any declivity like an inclined plane towards the rollers; the points of the spindles will also form an inclined plane parallel to the former, and, in proportion to the degree of obliquity, the threads will be farther insulated from each other. In this case, the face, or directing part of the guide, instead of being a straight wire, must be formed into inclined planes, corresponding to the slope of the points of the spindles.

The above can hardly be considered as a fully matured and digested plan, nor perhaps is it possible for the most comprehensive mind to enter minutely into every detail, investigate every minute property, and counteract every latent defect of complicated machinery, without the benefit of actual experience. If the outline of a plan, practicable and simple in itself, has been traced out; and if it has been proved, that this plan, if properly matured, and more early adopted, might have been the means of saving many hundred thousand pounds sunk in spinning machinery, much has been effected.

All machinery, kept in constant use, and subjected to constant friction, soon wears out; and must be replaced either by similar engines, or improved substitutes. The plan being submitted to public inspection, its advantages may be appreciated and adopted, and its defects removed, by attention and experience, like those of all infant machinery.

Mule-yarn.

Mule-yarn is used for a great variety of purposes. It has almost entirely superseded that spun on jennies, and water twist is now used only for hosiery and for purposes requiring great strength.

As mules require little power to work them, they are chiefly used where steam engines are employed, as in Manchester, Glasgow, and other manufacturing towns.

Water-twist.

Water twist, on the other hand, is spun principally in country situations, where power is cheaper, being produced by water.

Improvements in the machinery.

The rapid improvement which has taken place in the machinery of cotton spinning is unparalleled in any other manufacture. This rapid improvement is, perhaps, chiefly to be attributed to the liberality of those engaged in the cotton trade, in sparing no expense for making the necessary experiments. The great profits of the business for a long period put it easily in the power of those who, in any tolerable degree, understood it, to make such experiments with advantage.

Buildings.

The reader will even already perceive, that many of the contrivances in use are wonderful for their ingenuity, nor is the general *system* observed in conducting the operations of a well-regulated cotton mill, less wonderful. The buildings, for water spinning, usually consist of five or six stories. In the two first is generally placed the spinning frames, and over these, in the third, the *preparation* machinery, and in the fourth the reeling; but the arrangement of the buildings is various according to circumstances. The buildings for mules, commonly have the *preparation* machinery below. Each machine may be stopped separately from the rest, and even particular parts of the same machine.* Many of the mills are now built fire-proof, and steam is much employed for heating them. Gas light is used in several, and is likely to be still farther extended. †

Besides having the buildings fire-proof, the general use of cast iron in the framing, as well as in other parts of the machinery, contributes greatly to diminish the risk from accidental fire, at the same time that it costs less, while it is neater and more commodious. Indeed, without the use of this material instead of wood, it would have been impracticable to construct, in the time, the machinery now in the island. The pattern being once made, it is obvious that any number of the same parts may, in a very short time, be cast from it; whereas, when the parts are made of wood, the labour is continually repeated in the formation of every new part, although exactly the same as those already constructed.

From this general sketch of the machinery employed in the spinning of cotton, it is presumed the reader, previously unacquainted with the subject, will be prepared more easily to comprehend the subsequent explanation of machinery illustrated by Plates. Premising, however, that the jenny being now in a manner obsolete, we deem it unnecessary to give any Plates on that subject, and that we have elsewhere (see p. 279, &c.) described the process of *batting* or cleaning, and opening the raw material.

DESCRIPTION OF THE PLATES.

Description of the Plates.

Having elsewhere (see p. 279, &c.) described the process of *batting*, which, by opening the hard and compressed masses and disengaging the seeds or *gins*, prepares the cotton for carding; we come now to explain the operation of carding, by the help of Figures. This, as before observed, is the second elementary process. The mode which we mean to adopt in describing this and the following operations, is not to give representations of the whole machines, but rather what may be called diagrams of little more than the parts of the mechanism which

* For a more particular description of such contrivances than our limits will permit, see Buchanan's *Essay on Methods for Disengaging and Re-engaging Machinery.*

† See Buchanan's *Essay on Fuel,* &c. where the details of heating mills by steam are given, and also some account of the gas lights.

Cotton Spinning.

come into *contact* with, or *produce an immediate effect* on, the cotton in various parts of the process of spinning. This mode we conceive to be the most simple of giving the reader an intelligible description; for were the machinery for communicating the motions represented together with the framing, it would render the subject far more complex and obscure; and it is further to be observed, that the communicating machinery and the framing are very different in different mills, and are almost daily changing in new erections, while the parts coming in contact with the material under process remain nearly, if not entirely, the same. The mode we have adopted, we think, will not only give a better general idea of the subject, but will make the reader more readily comprehend the construction of the machines themselves when he has an opportunity of seeing them, than a more laboured and extended description, which representations of the whole machines would require, and of which our limits would not admit.

The operation to be performed by the carding machines (the first denominated the *breaker* and the second the *finisher,*) will probably be more easily understood, after we have considered the effect produced by the common *hand-cards,* which every one must have seen.

Carding machines.

The cards are composed of small wires stuck through a sheet of leather, forming a kind of brush. The wires are not perpendicular to the plane of the leather, but are all inclined in one direction at a certain angle. The hand cards consist of two boards with handles, each board having a sheet of cards nailed on it.

Plate CCXIII. Fig. 1.

AB and CD, Fig. 1, represent, in profile, part of the boards of a pair of hand cards; EF and GH the leather; and IK and LM the teeth.

Fig. 2.

Fig. 2. shows the form of one of the wires which are stuck through the leather; each wire forms two teeth.

If cotton be stuck into one of those cards, and the other drawn against it, the effect of repeated strokes of the empty card in this direction against the full one, will be a more equal distribution of the cotton upon the card teeth, which will have the effect of separating the fibres, disentangling every little knotty part, and laying the whole more straight. Now, if one card be drawn in an opposite direction over the other, it will, in consequence of the inclination of its wires, take the whole cotton out of the card whose inclination is contrary.

Fig. 3.

In order to explain the imitation of this process, as performed by the carding machines, we refer to Fig. 3. (being a vertical section of the *breaker,*) in which AB represents a cylinder (usually about three feet diameter and two feet long,) on which sheets of card are nailed parallel to the axis. The teeth all pointing, as shown in the Figure, in the direction of its motion, which direction is pointed out by an arrow. This cylinder is turned rapidly round, usually at the rate of from 60 to 80 revolutions per minute, by an endless leathern strap or belt on a pulley fixed on its axis. This cylinder being the first motion of the machine, all the rest are communicated from it.

The cylinder AB, is called the *main cylinder,* and revolves under an arch CD, consisting of several pieces of wood, each covered with a sheet card also parallel to the axis of the cylinder, with their teeth directed to oppose those of the cylinder, and coming nearly into contact with them, that is, within about one-twelfth of an inch of touching. These pieces, of which the arch consists, are called the *top-cards.*

Cotton Spinning. Carding machines. Plate CCXIII. Fig. 3.

The second cylinder EF is covered with card, the teeth meeting those of the main cylinder. This card is what is called a fillet, being a narrow ribband wound round the cylinder in a spiral form, so as to make the surface of the whole one uninterrupted sheet of card teeth. This cylinder moves in the direction shown on it by the arrow, but much slower than the main cylinder.

A certain weight of cotton is spread upon a certain length of the feeding-cloth GHI, which gradually advances. The cotton is taken from it by a pair of fluted iron-rollers KL, which deliver it equally to the main cylinder. This cylinder carries it round, and works it against the cards fixed within the arch. By this means it becomes equally distributed over the main cylinder. The cotton advances slowly from tooth to tooth, sometimes on those of the arch or top cards CD, and sometimes on those of the cylinder, until it has passed through the arch. It then comes to the second cylinder EF. Now, the property of two cards meeting each other being to distribute the cotton between them, the teeth of the second cylinder receives a full half of what is upon the teeth of the main cylinder. The cotton received by the cylinder EF, proceeds with it beneath till it comes to the opposite side, and is removed by the *taker-off.*

This curious piece of mechanism, the *taker-off,* consists of a comb of polished iron Q, which receives a reciprocating motion by means of sliding-rods MN working in guides above the comb from a crank at N. The comb moves so as to descend at the time when its edge is nearest the cylinder, and thereby combs or scrapes the teeth downward, and in consequence removes the cotton from the whole length of the cylinder EF. The motion of the crank is so quick, that the cotton is stripped off the cylinder in a continued and connected fleece. The disposal of this fleece forms the principal difference between the *breaker* and the *finisher.* In the *breaker* (which we are now describing,) it is received on a smooth cylinder OP, called the *lapping cylinder,* moving regularly at the rate the fleece is delivered, having a small roller R resting lightly above it, which causes the fleece to lap regularly on the cylinder, which continues to revolve until it has made about 20 revolutions, when, by means of an apparatus for the purpose, the machine stops, and the cotton is broken off by hand, forming a fleece, consisting of about 20 thicknesses, called a *lap,* which is ready to be carried to the *finisher.* This is the first operation in which the elementary process of *plying* or *doubling* occurs. The advantage of this process in this last part of the operation, is producing great equality in the thickness of the *lap,* which being fed on to the *finisher,* produces from it a regular sliver, upon which circumstance the perfection of the ultimate thread must depend.

Fig. 4. No. 1. and No. 2. represent a front view and plan of the *taker-off* of the *finisher,* on a larger scale; the same letters expressing the same parts as in Fig. 3. and 6. The taker-off is constructed in the same manner, both in the *finisher* and in the *breaker.* Fig. 4. No. 1, 2.

A vertical section of the *finisher* is represented in Fig. 5. The *lap* produced by the *breaker* is, in some mills, laid on a feeding cloth; in others it is placed in a tin canister; but in both cases it is fed into the main-cylinder by the feeding rollers, in the same way as in the *breaker.* The other operations of the cotton are the same in both machines until it passes the taker-off. Fig. 5.

Cotton Spinning.

Carding machines.

PLATE CCXIII. Figs. 4. 5.

The fleece from the *finisher,* instead of going to the lapping-cylinder, is gathered into a tin funnel marked *a,* (see also Figs. 4. and 5), and then passes between a pair of rollers *b, c,* which compress and flatten the fleece in its contracted state into a pretty firm and connected sliver or band, called a *card-end,* and deliver it into a can *d,* which, when full, is ready to be carried to the next operation performed by the drawing-frame.

The carding machines we have described, are those on the construction at present most approved; but many other constructions are employed. Instead of dead *top cards* are rollers, sometimes called *urchins;* but they are certainly more complex, and produce no superior effect. In some cases, the operations of *breaking* and *finishing* are performed on one large machine, having two *main cylinders* and two *doffing cylinders,* surrounded by a number of *urchins.*

This plan of double engines saves a great deal of attendance in conveying the *lap* of the *breaking card* to the feeding cloth of the *finisher,* but it is less perfect, as it has not the advantage of *plying* or *doubling* the fleece previously to the *finishing.* It is, however, sufficiently perfect for very coarse goods, and was the prevailing mode used in the preparation of cotton for common jennies.

Every part of the carding engines, where dust or films of cotton can escape, are now generally carefully enclosed, to prevent the pernicious effects on the lungs of the people employed in attending the engines.

We already mentioned, that in a cotton mill every machine, (and even particular parts of some machines), may be stopped or set agoing separately from the rest of the small machinery. There are a great variety of contrivances* for this purpose; and it may be proper to describe in this place one of them, remarkable for its simplicity and beauty, which is now commonly applied to carding engines. It is called the *fast and loose pullies,* or *dead and live pullies.*

The Fast and Loose Pullies.

Fast and loose pullies. Fig. 6.

The pulley B is fixed on the axle A of the main cylinder of the carding engine, and the pulley C, having a bush, is loose. The belt or band which conveys the motion from the mill-work, may at pleasure, either by hand or by a lever, be shifted from the one pulley to the other. When running on the loose pulley C, the axle stands still; when on the fast pulley B, the axle moves.

This contrivance of the fast and loose pullies is attended with no shock while throwing into action, and is perhaps the most perfect thing yet invented for the purpose in all cases where it can be applied.

Drawing.

Drawing.

The fourth elementary process, that of drawing, on which the great merit of Arkwright's system depends, is performed in the *roving frame* and *spinning frame,* as well as in the *drawing frame.* We may therefore first explain this elementary process. Its application in each of these different machines, when we come to speak of them, will then be more easily understood.

The object of the process of drawing is to imitate the human finger and thumb in drawing out the fibres; and although the first idea of the mechanism was taken from the elongation of a red hot bar of iron, by means of a pair of rollers, yet it is obvious, that although a sliver of cotton may be compressed by a single pair of rollers, it cannot be elongated; but, as shall immediately be explained, that effect may be produced by *two* pair of rollers.

PLATE CCXIII. Fig. 7.

In Fig. 7. A represents an iron roller fluted longitudinally with sharp flutes. B is another roller, covered with leather, and pressed downward upon A by a weight. If a sliver of cotton be put between them, while moving in the direction expressed by the arrows, it will be *compressed* but not *extended.* If the sliver be made to pass through a second similar pair of rollers, if they move in the same direction, and at the very same velocity, no extension of the sliver, even in that case, can take place; but suppose C and D to move at double the velocity of A and B, then the sliver will be extended to double its former length; for C and D will take up the cotton faster than A and B deliver it. It must either be forcibly pulled through the first pair of rollers, or it must be extended a little by the fibres slipping among each other, or it must break. When the extension, however, is moderate, the effect is merely to draw the fibres into a more favourable situation for extension. The relative motion of the rollers, as formerly mentioned, is called their *draught.*

The Drawing Frame.

Drawing frame.

Besides merely *drawing,* the machine we are now to describe, (the drawing frame), doubles or plys the cotton; and these elementary processes combined, produce, besides the effect of equalizing the sliver, that of laying the fibres of the cotton nearly parallel to each other.

PLATE CCXIII. Fig. 8. PLATE CCXIV. Fig. 1.

Fig. 8. of Plate CCXIII. and Fig. 1. of Plate CCXIV. represent what is termed one *head* of a drawing frame. A *frame* usually consists of several *heads,* which are in fact each a distinct machine, but so arranged on a frame, as to form one system. If one head, therefore, be understood, the whole system is easily comprehended.

A represents a group of four tin cans brought from the carding machines. The four *card-ends* from these cans are passed through the rollers B, C and D, E, (which have, suppose, a *draught* of four.) The slivers are then united and conducted by a pair of rollers F, G, (which do not extend the cotton,) into another can H, which sliver being extended to four times the length of the *card-ends,* is therefore the same size as one of them, but is more uniform, and the fibres are laid more straight.

This operation being repeated, through several other *heads* on the same frame, the fibres of the cotton are laid nearly parallel, and the sliver becomes still more uniform, and is then ready to be carried to the roving frame. The number of these operations, and the *draught* of each *head,* and also the number of plies, are optional, and are varied according to the nature of the cotton, or other circumstances. For the sake of simplicity, we have described each *head* as having only two pair of rollers, although three or more pair are now often used in each head. In this last way the cotton is more gradually and equably extended than when the whole draught is produced at once.

Roving.

Roving.

The fibres of the cotton having been laid parallel by the drawing frame, it is necessary to reduce the sliver to

* See Buchanan's *Essay on Methods of Disengaging and Re-engaging Machinery while in Motion.*

Cotton Spinning.

a convenient size, preparatory to reducing it still further by the spinning into a small thread; and to accomplish this purpose, it becomes necessary to give the sliver a degree of twine while drawing, in order that it may have adhesion sufficient to undergo the stress of spinning.

The making of good rovings is a most essential part of cotton spinning. They ought to be uniform in size, have an equal degree of twist in every part, and that twist should be no more than what is just sufficient to give the requisite degree of strength.

A great variety of constructions of machines for roving have been in use at different periods. We shall begin with that which was used by Sir Richard Arkwright.

The Can Roving Frame.

The *can* roving frame. Plate CCXIV. Fig. 2.

One head of the roving frame is represented in Fig. 2. Each *frame* contains several similar *heads*; but by tracing the progress of one roving, that of the rest will be easily comprehended. A, A represent two tin cans, each containing a sliver from the drawing frame. The slivers enter together between the rollers *a b c d.*

The rollers of this machine are similar to those of the drawing frame. The sliver, after being reduced by passing through the rollers, is received into a can or box B (in the form of a truncated cone) through a small funnel *e* at its upper end. This box is supported at bottom by a pivot *f*, and kept in rapid motion by a band. To keep the box steady as it revolves, the neck of the funnel *e* is guided by a collar. The boxes have each a door to open on one side for taking out the cotton rovings. This door is secured by a ring *g*, which fits the outside of the box, and when pushed down, keeps the door shut; but when drawn up to the top, the door may be opened and the rovings taken out.

The sliver, after being reduced by the rollers passing through the funnel *e* into the box, is twisted, and by the centrifugal motion coiled round within. The attendant knows, by experience, the time when the box is full, and lifting up the ring, withdraws the rovings. They are then ready to be carried to what is called the *winding block.* This is a very simple machine (moved by hand) by means of which the roving is wound on bobbins.

This mode of roving was found defective in two respects: 1st, The twine was not equally diffused over every part. 2d, The winding the cotton by a separate process damaged the tender rovings.

To remedy the first of these evils, Arkwright tried rollers on the top of the revolving can or box, which were contrived to move at the same rate as the drawing rollers delivered the roving; but in practice this mechanism was found to be attended with considerable objections, and for that reason has been abandoned for other and more perfect machinery.

The following method is now much in use: Instead of taking the rovings out of the box and winding them on bobbins, a can is put within a revolving frame, (called a skeleton,) having a top and bottom, similar to those of the revolving box. The rovings, when the cans are full, are carried, without being wound on bobbins, to be further reduced and twined on a machine called a *stretching frame.* By this method the damage which the roving otherwise sustains in winding by hand is avoided.

The Jack Frame.

Jack frame.

To obviate both the evils mentioned above, many contrivances were tried. A machine called a *jack in the box* was long in use in some mills. It was very ingenious in its construction; but its great fault was its complexity. It consisted of a frame revolving rapidly instead of the revolving box or can of the *can frame.* Within this revolving frame a small cylinder moved vertically, the surface of which had the very same velocity as the surface of the front roller of the roving frame. Upon this cylinder the bobbin was placed, which, by contact, revolved and took up the roving at the same rate at which it was delivered by the rollers. At the same time the horizontal rotatory motion of the jack gave the twist to the roving, a guide-wire also built the roving regularly on the bobbin.

Plate CCXIV. Fig. 3.

The sketch in Fig. 3. will give an idea of this machine, and of the simple contrivance for making the *surface* of the bobbin, whether empty or full, always move at the same velocity.

A is the cylinder, revolving at such a rate that its surface has the same velocity as that of the front roller. B the bobbin lying on it. C the guide-wire.

But this machine, (the jack in the box,) has been superseded by another, which is more simple, while it is calculated to produce the same effects, viz. diffusing the twine equally in every part, and saving the winding of the rovings by hand. This is effected by means of the spindle and flyer, similar to those of the common flax-wheel; and although Arkwright tried to apply this part of machinery to roving, he did not succeed. He found difficulties which were, even to him, insuperable, but which time and experience have at length overcome.

Spindle and Flyer Roving Frame.

Spindle and flyer roving frame. Fig. 4.

This machine has its rollers, &c. for drawing or reducing the sliver, the same as the roving frames already described. Instead of the revolving boxes, there are spindles AA, Fig. 4. each of which has fixed at its upper end a forked piece of iron called a *flyer.* One of the legs *b* of the fork is made tubular, to receive the roving as fast as it is twisted by the motion of the flyer, and to convey it to the bobbin, which is fitted loosely on the spindle.

The rollers deliver the reduced sliver to the flyers on the top of the spindles, where it passes through an eye-hole *a* of the flyer, exactly above the centre of the spindle, and thence proceeds through the tube *b* to the bobbin *c.* The tube of the flyer running swiftly round the bobbin, lays the roving on it as fast as the rollers deliver the cotton. In the common flyer of a flax wheel, there are teeth from one to another of which the thread is shifted from time to time by hand, in order to fill the bobbin regularly; but to answer this end, and in a more perfect manner, this machine is so constructed, that the bobbins rise and fall on the spindles, that they may lay the roving from the end of the tube regularly upon the length of the bobbin. This rise and fall of the bobbins is accomplished by the motion of the wooden rail BB, which, by a piece of mechanism, is kept in regular, slow, alternate ascending and descending motion.

The application of the spindle and flyer to roving, as far as we have yet described it, is the same as was tried by Sir Richard Arkwright, upon finding the defects of his roving can frame. But the objections to the machine in this state, and which he found unsuperable, were, that the bobbins when they became filled with rovings, being much heavier than when empty, required much more force to drag them round. The bobbin rested on the rail, and was retarded from moving as fast as the spindle by friction only. Had it moved as fast as the spindle, it is obvious it could not take up the roving. Again, had it been stationary, the flyer would have had the effect of stretching and breaking the roving. The bobbin therefore required a slow motion, and that motion to increase gradually as the bobbin became full; for the quantity of roving taken up by the bobbin depends on the difference between the motion of the flyer, and bobbin which follows it. But not having any proper means of producing this varying motion, the weight of the bobbin increasing, increased the friction, and thereby stretched the roving, and consequently rendered the machine inadequate to its proposed end.

This objection is now obviated in the improved spindle and flyer roving frame, by means of mechanism, which communicates such motion to the bobbin, that it will take up the roving just as fast and no faster than the front roller delivers it. To effect this, it is necessary that the velocity of the bobbin be altered every time the bobbin has a new layer of roving beginning to be lapped on it, for the bobbin increases in diameter, and the velocity of its acting circumference must at all times remain the same.

The mechanism, by means of which this change in the velocity of the bobbin is accomplished, is different in different mills, or in different machines. We may shortly describe the two methods most approved.

In some machines it is produced by means of two conical barrels of the same dimensions, but placed with the larger end of the one opposite the smaller end of the other. The one of these barrels moving uniformly, communicates motion to the other by an endless strap, which, by being shifted toward either extremity, varies the motion of the other barrel. The belt, or strap, remains equally tight in every part of the barrels, for the one barrel increases in diameter exactly as much as the other decreases. From the second barrel, motion is conveyed to pullies resting on the bearer or rail BB, and having the spindles passing through the centre of each. The bobbins rest on those pullies, and are carried round along with them.

In other machines, instead of the conical barrels, two wheels, having no teeth, but covered with leather, the one bearing on the face of the other, moves it by contact, and varies the motion, by approaching and receding from the centre of the face wheel. For a more particular account of these two pieces of mechanism, and other similar contrivances, see Buchanan's *Essay on changing the velocity of Machinery while in Motion.*

Although this species of roving frame requires very accurate adjustment, yet, from its merits in other respects, it promises to be generally adopted in this important department of cotton spinning.

The rovings prepared either by this machine, or otherwise, are carried to the next operation, which in water spinning is performed on what is termed the water spinning frame.

Water Spinning Frame.

Water spinning frame.

We come now to describe the *water spinning frame*, the machine for which Sir Richard Arkwright obtained his first patent. A general idea of it may be formed from the preceding description of the application of the spindle and flyer to roving; but as the thread in spinning has sufficient strength to bear the drag of the bobbin, no mechanism for regulating it is required, but the bobbin rests on the bearer, and is retarded by friction from moving as fast as the spindle.

Plate CCXIV. Fig. 5.

Fig. 5. is a profile of one head of the spinning frame. Some use heads of four spindles, and others of six spindles. A is the binder, or pulley, loose on the axle CD. The binder is kept in motion by a broad belt from a drum on an upright *shaft* of the mill work. E is the *list pulley* fixed on the axle CD. In order to disengage, or re-engage the axle CD from the list pulley E, and thereby to stop, or set agoing, the head of spinning connected with it, a contrivance called the locking bayonet is used. It consists of a kind of fork *a b c d*, which passes through two holes in the *list pulley* E. The bayonet is moveable upward and downward on the axle CD, which passes through its collar *b c*. Around this collar there is a groove, into which part of what is called the *lifter* projects, and by means of which the bayonet is, by hand, at pleasure raised or depressed. While the bayonet is in the situation represented in the Figure, the binder A keeps running on its bush, and the axle CD is at rest.

In order to set the axle in motion, the bayonet is depressed, and its legs *a* and *d* lay hold of two projecting teeth, or pieces of iron, in a groove in the upper end of the binder A. The list pulley E is thus locked or connected with the binder, and it and the axle are carried round together, and thereby motion is given to the whole of the moving parts of the *head*.

This contrivance of the *locking bayonet* is used for disengaging the drums on the upright shafts of the millwork. It was also used in Arkwright's can, roving frames, and various other parts of cotton machinery; but the contrivance denominated the *fast and loose pullies*, or, as they are sometimes called, the *dead and live pullies*, already described, has now in many instances superseded the bayonet, to which it is to be preferred in all situations where circumstances will allow, as by it the belt carries the pulley into motion without any shock. But a great improvement on the locking bayonet has of late years been introduced. Instead of making it, when thrown into gear, strike against permanently fixed teeth, or a fixed clutch, it strikes against the ears of an iron hoop, which embrace a fixed pulley. In consequence of this construction, the machine is not suddenly jerked into motion when the bayonet is let down, but the clisp slips round a little until its great friction gradually brings the machine into motion. See Buchanan's *Essays.*

The elementary process of drawing, (or further reducing the roving into a size proper for a fine thread) is performed in the *spinning frame* by fluted rollers, &c. similar to those of the roving frame, but instead of two, three sets of rollers are used, to which motion is given in the following manner: On the top of the axle CD is a pinion F, which works into a face wheel, represented by a dotted circle, (in order that the rollers may be better seen, of which a vertical section is shewn in the Figure,) fixed on the end of the front roller *e*, from which, by a train of wheel-work, motion is communicated to the middle roller *f*, and the back roller *g*. This train of wheel-work is calculated to give the requisite degree of *draught*, (usually about seven or eight.) Between the mid and back rollers there should be little more *draught* than what is just necessary to begin to pull the rove from the back rollers; for it is found that the thread is more even when the fibres are pulled by the front rollers from between the middle rollers. The back

Fig. 5.

Cotton Spinning.

PLATE CCXIV. Fig. 5.

rollers serve to keep the roving from being pulled too fast forward; the top roller *h* in the middle is much lighter than the other top rollers, and permits the fibres to move freely among themselves in reducing the roving.

GH represents the spindle, to which motion is communicated from the list pulley E, by means of a strap formed of cloth listing IK, which goes round the *spindle shaft* at I. *i k l* is the flyer, the legs of which consist of two solid pieces of iron, twisted somewhat like a corkscrew at the lower extremities *i* and *e*, in order to conduct the thread to the bobbin *m n*.

The operation of this machine will now be easily explained. The bobbin containing roving L is placed in a frame behind. From it the roving passes to the back rollers *g, p*, through a wire eye *o*, fixed in a wooden rod *r*, that has a slow reciprocating horizontal motion. The use of this motion is to make the roving traverse a little on the rollers, to prevent it from wearing them, or bruising the leather too much in one part. The roving being reduced in its passage between the three sets of rollers, proceeds through the *leader q*, (which is an eye formed of wire fixed in the *leader board*) to the flyer, which twists and lays the thread on the bobbin *m n*, in a similar manner to what we have already described of the flyer used in the roving frame.

The ascending and descending motion of the bobbin for building the thread regularly, is produced as follows: A wheel in the form of a heart, called the *heart wheel*, moves with a regular vertical motion, and acts on a roller, which, by means of levers, alternately raises and depresses the bobbin rail M. This rail has pieces of thin wood *x y* projecting from it, which go under the bobbins, and on which pieces they rest and are moved along with the rail. The motion is so calculated, that when the bobbin is full of yarn it is swelled a little somewhat into a barrel form. The bobbin (as was observed of the spindle and flyer roving) does not revolve with the velocity of the spindle. In the spinning frame it is *retarded by friction*, which is increased to the requisite degree by means of washers of cloth or leather; then the thread, by the motion of the flyer, drags the bobbin about after it, with a velocity equal to the difference between the motion of the flyer and the motion of the thread delivered out by the front rollers. The thread is sufficiently strong to bear, without injury, this drag of the bobbin, and therefore, as before observed, it does not require the mechanism to regulate its motion, which is necessary for the delicate rovings.

When the bobbins are full, the attendants take them off the spindles. The dexterity with which this work is performed, as well as that of the mending of the threads, (for which last purpose it is not always necessary to stop the spindles,) is almost incredible to those who have not witnessed these operations.

The bobbins, when taken off the spindles, filled with water-twist for warps, are carried to be reeled. But stocking yarn undergoes the operations of doubling and twisting. This last kind of yarn is softer than common water twist, and requires to be more even, because, in a stocking, the whole of the texture at any one part is formed by the same thread, and any defect will make a bar in the stocking, whereas, in cloth, so many different threads cross each other at one place, that a defect in any one thread is seldom perceptible in the cloth. In order to obtain greater evenness, stocking yarn is usually spun from double rovings, wound on the same roving bobbin. The roving can frame is therefore still used in the preparation for this kind of spinning.

Cotton Spinning.

The Throstle.

Throstle.

Water twist is spun on a spinning frame of another form, called the throstle. The operating parts are the same in both machines, but the mechanism which actuates them is different. A very short description, however, after what we have said of the spinning frame, will suffice.

The rollers and spindles are similar to those of the water frame, but instead of *heads*, each of which may be stopped independently of the rest, the whole rollers of one side of the frame are coupled together, and the whole of the spindles of both sides of the throstle are driven, by means of bands or lists, from a cylinder A, Fig. 6. which extends the whole length of the machine. This cylinder receives its motion by a belt, and from its axle motion is communicated by wheel work to the rollers. Thus, by stopping the cylinder, which has dead and live pullies at the end of its axle, where it receives its motion, we stop the whole machine.

PLATE CCXIV. Fig. 6.

This machine is more simple, consists of fewer parts, and of course costs less than the water spinning frame. It is generally stated to require less power to work it. But it has an evident disadvantage, viz. that in taking off the full bobbins, the whole spindles of the throstle must be stopped; whereas only a single head (of four or six spindles) of the water frame requires to be stopped during this operation. On the whole, cotton spinners are still divided in their opinions as to the comparative advantages of these two machines.

The Reel.

The reel. Fig. 7.

In some mills the reels are moved by hand, in others by power. A, Fig. 7. is a board going the whole length of the reel. In this board a number of wooden pins are fixed, of such a size that the bobbins may turn freely on them. B represents one of the bobbins. The thread from the bobbin is conducted between several wires, and has a turn round one of them, in order that it may be conducted with sufficient tension to the reel CDE. It consists of six rails *a a a*, &c. which extend parallel to the axis the whole length of the reel, and on which the thread is wound. The dimensions of the reel are such, that it requires exactly one yard and a half to go round it. The length depends upon the number of bobbins which it winds at once—sometimes as many as 50. The reeler begins with making the ends of all the threads fast to one of the rails *a*. By means of wheelwork, when the reel has made 80 revolutions, (one lay) a bell or click strikes, the reel is stopped, and the lays are tied with pieces of thread, in order to keep them distinct. Seven of these lays form a *hank*. When the hanks are completed, they are taken off the reel. The arms of one of the rails is hinged, which permits it to be folded inward, in order to take off the yarn with ease, by slipping the hanks to one end of the reel, which is lifted off its bearings for the purpose.

The hanks are then twisted into knots, and weighed on the quadrant, or averaged on a scale, in order to ascertain the size of yarn. It is afterwards made up in cubical bundles for the market.

Having thus concluded our proposed description of the machinery of *water spinning*, we shall now proceed to finish what we intended to say on the subject of *mule spinning*.

Cotton Spinning.

Mule spinning.

Mule Spinning.

The preparation machinery in this species of spinning, as has already been observed, is the same as that of water spinning. Mule yarn differs in this respect from water twist, that in the operation of spinning the former, an additional *elementary process* is introduced, namely, that of *stretching,* which takes place after it has been *drawn* by the rollers. The effect of this *stretching* is twofold; it makes the yarn finer than it would be by *drawing* alone, and it causes the yarn to be more even: for those parts of the thread which are of the greatest diameter, as delivered by the rollers, receive less of the twine from the spindles than the smaller places, and consequently the larger yield more easily in stretching; meanwhile, the twine becomes more equally diffused over the whole thread. But the great advantage which the *mule* has over the *water-frame,* is in producing much finer yarn than is possible by the latter machine. The principal reason seems to be, that, in the water-frame, the yarn must have sufficient strength to drag the bobbins; whereas, in the *mule* no bobbins are used, and the yarn is built on the spindles in such a manner as to throw little or no stress on the yarn.

The rollers for *reducing* or *drawing* the roving in the mule are similar to those of the throstle, a number of heads being coupled together. The spindles (of which there are now usually about 300 in one mule) are like those of the *common* jenny, having neither bobbins nor flyers. They are disposed and revolve on a carriage, which recedes from the rollers, while the thread is delivering.

For many years the mule was worked entirely by hand; but now the whole of its operations, excepting the returning of the carriage, and the building the thread on the spindles, is performed by power. We shall, as in other occasions, confine our attention principally to trace the progress of a single thread.

Plate CCXIV. Fig. 8.

In Fig. 8. A represents a roving placed in a frame behind the drawing rollers CDE. After passing from between the rollers, the reduced roving goes on to the spindle F, which is placed a little inclining. The spindles are disposed on the carriage FGHI.

The machine being put in motion, the carriage recedes as fast as the rollers deliver the reduced roving; the spindles at the same time rapidly revolving, giving sufficient twist to the yarn to bear *stretching.* After the rollers have delivered a certain length (a yard, for example) of yarn thus partially twisted, they stop, but the carriage continues to recede, (half a yard further, for example) and the spindles to revolve. The yarn is thus *stretched,* and forms a fair even thread. In order to save time, the spindles move more rapidly during the process of *stretching.* The mechanism, by means of which this increased rapidity is effected, is called the *double-speed.*

The yarn being sufficiently hard twisted, the machine disengages itself from the rest of the moving parts of the mule. The attendant then returns the carriage home to the rollers. With one hand he manages the fly-wheel, and by it the movement of the spindles; while, with the other, he directs the wire *a* of the folder *a b,* (which turns on a pivot at *b,*) so as to build the thread on the spindle in a conical form, denominated a *cop.*

The spinner, from habit, communicates the motion of the handle, so as to keep the threads always at that degree of tension, which, without injuring the thread, will make the cop firm and compact.

These several operations being repeated until each of the spindles has a cop on it of a proper bulk, they are then taken off to be reeled, which is done in the same manner as we have already described of the water-twist. The cops, indeed, are often used without being reeled, particularly for weft; and, on other occasions, the yarn for warp is wound off the cop immediately on the warping bobbins.

The Stretching Frame.

Stretching frame.

We already observed, that the rovings for mules commonly receive their last reduction previously to the spinning, on what is called the *stretching frame.* The *construction* of this machine, excepting in its proportions, is the same as the mule. The spindles, in order to give room for larger cops, are more distant from each other.

But although its *construction* be the same as the mule, its *operation* is different, in as far as it does *not stretch* in the sense to which we have confined that word, but merely reduces the rove by the process of *drawing* by means of the rollers.

Description of the buildings, &c.

Having thus attempted a description of what is called the *small* machinery of cotton-mills, we shall say a little with regard to the mill-work, or *great gear,* and the buildings which contain the whole, beginning with those for spinning water-twist.

This species of yarn, as already observed, is spun for the most part in those situations, where there is water sufficient for driving the machinery.

The buildings are usually five or six stories high, and from 28 to 33 feet wide. Their length depends much on the number of spinning frames contained in one floor.

A large water-wheel is usually placed in the middle of the lower part of the building. In some cases, strong lying-shafts convey the motion from rings of teeth attached to the water-wheel, to each end of the ground-floor. These lying-shafts give motion to an upright shaft, opposite the abutment of each window; and the whole is supported in the lower story by strong framing, independent of the wooden floors, so that much of the tremour of the great gear is thus confined to the framing. The upright shafts passing up through the spinning rooms, have a drum opposite to every two spinning frames, to which, by a leathern belt, it gives motion. A few of the upright shafts are continued up to the carding rooms, and give motion there to the preparation machinery.

In other cases, the water-wheel, having teeth on it, moves two strong upright shafts, conveying the motion to the stories above; and, from crown-wheels on them, lying-shafts are worked, that convey motion to the drum-shafts in the spinning rooms, and other lying-shafts to the preparation machinery. In the first of these cases, the stair is usually placed at one end of the building; in the second, in the middle. This last arrangement is most generally adopted.

In order to prevent the risk of fire, it is usual to conduct in out-houses all the business which does not require machinery worked by power; and some even prefer, on that account, to have the preparation machinery in a separate building.

To describe more particularly the many ingenious contrivances in the construction of mill-work and buildings of an extensive set of cotton works, would exceed the limits which we have assigned to this article. (O)

COTTUS. See ICHTHYOLOGY.

COTULA, a genus of plants of the class Syngenesia, and order Polygamia Superflua. See BOTANY, p. 297.

COTYLEDON, a genus of plants of the class Decandria, and order Pentagynia. See BOTANY, p. 219.

COTYLEDONS. See BOTANY, vol. iv. p. 36, 47.

COUBLANDIA, a genus of plants of the class Polyandria, and order Monogynia. It is placed by some botanists in the class Monadelphia, and order Polyandria. See BOTANY, p. 241.

COUCHING. See EYE and SURGERY.

COVENANT, in the English law, is a species of contract, whereby a party to a deed agrees to do or omit some direct act. The remedy for a breach of such contract is by a *writ of covenant;* by which process the plaintiff may recover damages, in proportion to the injury which he has sustained. In the case of a covenant *real,* to convey or dispose of lands, the remedy is by a special writ of covenant, for a specific performance of the contract, concerning certain lands particularly described in the writ. It is upon this process, that *fines* of land are usually levied at common law. See FINE. (z)

COVENANT, in Scottish history, is the name given to a solemn engagement entered into by the people, for the preservation of the national religion. Its origin may be traced to the reformation; and the name was evidently adopted from the frequent covenants of Israel with God. During the progress of the reformation, the covenant was twice renewed; and it was at length revived in a more permanent form, by the *Tables,* or commissioners from the different orders of *Supplicants,* against the canons and liturgy of the English church, in the reign of Charles I.

This memorable deed was prepared by Alexander Henderson, the leader of the clergy, and Archibald Johnston, afterwards of Wariston, an advocate, in whom the supplicants chiefly confided, and revised by the Lords Balmerino, Loudon, and Rothes. It contained a general profession of the reformed religion, and a minute abjuration of the rites, ceremonies, doctrines, and whole discipline of the Romish church; and enumerated a variety of statutes, to vindicate the renewal of this intolerant confession of faith. A bond of union was subjoined, containing a declaration, that the liturgy and canons, as if expressly prohibited, were virtually renounced in the confession of faith; and concluding with an obligation to resist those innovations, to defend each other, and to support the sovereign in the preservation of religion, liberty, and law. On the 1st of March 1638, this covenant was subscribed and sworn in the Grey Friar's church at Edinburgh, by the nobility, gentry, clergy, and burgesses. Copies were immediately circulated throughout the different parts of the kingdom, and within a short space of time, it was embraced, with the most ardent enthusiasm, by almost the whole of Scotland. In the year 1643, the famous *Solemn League and Covenant* was concluded between the Scots and English, with the view of uniting the two kingdoms by the bond of religion.

In 1660, the covenants were virtually repealed by the general *rescissory* act; and, in 1663, a declaration was passed by the parliament, to abjure the covenant under severe penalties. See Laing's *History of Scotland;* and the article SCOTLAND in this work. (z)

COVENTRY, a city of England in Warwickshire, in Lat. 52° 24′ 26″.3 N. and Long. 1° 30′ 5″.5 W. from Greenwich Observatory, as accurately determined for the spire of St Martin's church in 1790, in the course of the trigonometrical survey carrying on by the royal engineers. This city is 91 miles N.N.W. from London, and 49½ miles N. of Oxford, situated on a gentle rising ground on the river Sherburn. It is both a city and county within itself, sending two representatives to the House of Commons; having a weekly market every Friday, and an annual fair of eight days, commencing on the festival of the Holy Trinity.

Its scite is chiefly on a remarkable stratum of red sand, in some places hardened into stone; whence, at no great distance to the N.W. the coal strata begin to crop out to the day. The tillage lands in the neighbourhood contain great numbers of rounded quartz pebbles, black, deep red, brown, white, and veined, from the size of an egg to that of the fist, and with which the streets are paved; and in the neighbourhood there is a quarry of soft grey stone, easily reduced to sand, which serves the inhabitants for various domestic purposes, and for mixing with lime mortar.

Having never suffered considerably by the ravages of fire, the city still bears strong marks of antiquity, in its narrow, dark, and winding streets; and many of its more ancient houses hang forwards so much, as almost to meet above from opposite sides of the way, through the absurd projection of their several stories beyond each other as they rise in height. It contains three parish churches, all standing in the same cemetery, in which also there formerly stood a cathedral, now in ruins. The steeple of the church of St Michael is reckoned one of the finest in Europe, all its parts being in the truest proportions to each other, insomuch that it was reckoned a masterpiece in architecture by the celebrated Sir Christopher Wren. The body of this beautiful church was partly rebuilt in 1434. The steeple, which is 303 feet high, was begun in 1372 by two brothers, Adam and William Batoner, who expended upon it L. 100 yearly, for 22 years; and it had to be afterwards completed by two ladies of the same family. The tower is richly ornamented with niches, containing statues of saints; and the taper spire rises majestically from an octagonal base. Besides the three established churches, there are five places of worship belonging to various denominations of dissenters, a Quaker meeting-house, and a Roman Catholic chapel.

There was formerly a monastery of Grey Friars, and a beautiful octagonal tower and spire remain on the south side of the city, formerly belonging to their church.—These friars were celebrated for performing sacred mysteries, or pageants so called, to the people on the day of *Corpus Christi,* which they exhibited on a moveable stage in different parts of the city; their scenes or interludes amounting to about forty, representing various stories from sacred writ, from the creation down to the final judgment. The Grey Friars' hospital was founded in 1529, by William Ford, merchant, and augmented by his executor William Pisford, and subsequently by other benefactors. In this, fourteen poor aged persons are maintained, for whom also a nurse or female attendant is provided. St John's Hospital, in Bishop Street, was founded in the reign of Henry II.; and in that of Henry VIII. became the property of John Hales, who left an estate of L. 43 a year, since greatly improved, to

Coventry. endow a free school, which is now held in an aisle of the chapel.

The Carmelites, or White Friars, had also a monastery and church at this place, founded in 1342, by Sir John Poultney, who had been four times lord mayor of London. There was likewise an hospital for lepers, founded by Hugh Earl of Chester, the ruins of the chapel and gate-way of which still remain. Bablake Hospital was founded in 1506, by Thomas Bond, mayor, in which he placed ten poor men, a woman to take care of their bodies, and a priest to superintend their spiritual concerns. At the suppression of the religious houses, Edward VI. vested its revenues in the corporation, which now supports there eighteen old men, with a nurse or matron. Part of the same building is appropriated for the residence of a number of poor boys, on a foundation instituted by Thomas Wheatly, mayor, ironmonger, and wool-card maker, in consequence of the following singular incident. Having sent his servant to Spain, in 1556, to purchase some barrels of steel gads, or ingots; he bought, by some inexplicable mistake, and brought home, a number of casks filled with ingots of silver and cochineal, which were offered for sale in an open fair, as the articles he was directed to purchase. His worthy master made afterwards every effort to discover the person who sold these, but ineffectually; and finally, converted the whole value, together with all his own property, to the establishment of this charity.

This city boasted formerly of a beautiful cross, 57 feet high, and richly ornamented, which was erected between 1541 and 1544, by Sir William Hollis, lord-mayor of London. After becoming greatly mutilated, this has been lately entirely removed.

St Mary-hall, near the church of St Michael, a magnificent structure, was erected in the reign of Henry II. The great room has a large window at the north end, containing in nine divisions, the whole length effigies of nine English kings, with various armorial bearings; and the windows on the east side contain portraits of many eminent persons, formerly members of the Trinity gild, who became possessed of this hall on the union of the two gilds. Draper's hall is a handsome modern structure, ornamented with Tuscan pilasters.

Coventry has long possessed rich and flourishing manufactures. Anciently, the chief of these were cloth, and caps, or bonnets, which flourished here from before 1346 till the eighteenth century, when the cloth manufacture was transferred to Yorkshire, that of bonnets having long expired through the prevalence of hats. In a later period, shags, tammies, camblets, lastings, and other woollen stuffs were manufactured here to a great extent. On the decline of these, the manufacture of silk ribbands was introduced about an hundred years ago, and is now carried on to a vast extent in the city and neighbourhood. Before 1581, this city was celebrated for the manufacture of thread, the excellence of the blue thread made and dyed there being almost proverbial; but the art seems now lost.

Though an inland city, Coventry enjoys great facilities for trade and manufacture, by means of the Coventry and Oxford canals, which join the Grand Junction and Grand Trunk canals, affording communications with London, Liverpool, and Hull, and serving for the conveyance of coals from the coaleries of Hawksbury and others. The Coventry canal terminates on the top of a steep hill a little above the town, where two parallel branches, or basins, include a spacious yard between them, for the landing and stowage of coals, lime, timber, and other rough and bulky commodities. The canal basins are skirted by embanked wharfs, raised so far above the level of the yards, that carts and waggons, backed up against them, have their bottoms nearly on a level with the wharfs and gunwales of the loaded boats, affording the utmost facility and dispatch for loading and unloading. At one place, the bank or wharf is occupied by a range of warehouses, having penthouse roofs projecting over the boats, which can thus be loaded or unloaded safely in any weather. At intervals there are gateways communicating with the wharfs, yards, and warehouses; and in one of the gateways is a weighing machine, for ascertaining the loads of coals or other heavy goods. Coventry.

About two miles and a half from Coventry, the canal is carried over the river Sow and its valley by an aqueduct bridge and considerable embankment; and half a mile south-east of Bedworth, it is conducted through the grand central ridge of England, by an immensely deep cutting in a stratum of red clay. A branch and rail-way proceed from Shackleworth bridge to the coaleries at Bedworth town, which are 120 yards deep. Sir Roger Newdigate's canal branches off on the north-west of the summit before mentioned, and, after rising by several locks, crosses the same summit again at a higher level before entering his park. About a mile from Coventry, a meadow is occasionally irrigated by the waste water of the canal, discharged over a slope in the bank, or a trunk through its thickness; a practice which may be imitated to great advantage in many similar situations.

In the Saxon Chronicle, the name of Coventry is Couentre; and in some of the old monkish historians, it is called Couventria. Antiquaries have derived the name from *coven*, quasi *convent*, and *tre*, a British word signifying *town*, as if the Convent-town; a strange conjunction of different languages, scarcely admissible. Others have supposed, that the original name of the river Sherburn may have been *Cune*; and thence *Cune-tre*, changed to *Coventry*, signifying the town on the Cune. The convent to which this city is supposed to have owed its name, is said to have been anciently possessed by nuns under the governance of a holy abbess, St Osburga. However this may have been, it appears to have been destroyed in 1016, during the invasion of Mercia by Canute. On its ruins, Leofric, Earl of Mercia, founded a new monastery in 1043, for an abbot and twenty-four Benedictine monks. According to William of Malmsbury, this monastery was afterwards so much beautified and enriched, that Robert de Limesie, bishop of the diocese in the reign of William Rufus, is said to have taken 500 marks of silver from one beam that supported the shrines.

Leofric married the lady Godeva, famous in legendary story; who, compassionating the oppressions suffered by the inhabitants from their lord, incessantly solicited in their favour, till at length, wearied by her importunities, he peevishly agreed to grant them a charter of immunities, on condition that she would ride naked through the town, in sight of all the people. To this she consented, modestly accomplishing the indecent task, by covering her naked person by means of her flowing tresses, and thus obtained a charter of freedom for the townsmen. Long afterwards, in the reign of Richard II. the grateful inhabitants placed portraits of Leofric and Godeva in one of the south windows of the church of the Holy Trinity, representing the Earl holding out the charter, with an in-

Coventry. scription, or scroll, addressed to the Countess, in the following words:

"I Luoricke, for the love of thee,
Do make Coventry toll free."

Others assert, that Leofric, repenting of his rash and indecent proposal, commanded every one of the inhabitants to retire from the streets and fronts of the houses during the progress of the lady, under pain of death; but that one curious person contrived to have a glance at the naked countess, from which he obtained the name of *Peeping Tom* of Coventry, and the honour of a statue in the act of looking from a window in one of the streets. It is certain, however, that this event is annually commemorated by a procession, in which the naked figure of a woman is paraded through the streets on horseback. In the last edition of Cambden's *Britannia*, by Gough, there is inserted a dissertation by Dr Pegge, to prove that this is a mere legendary story, resting on no historical document.

In the reign of Edward III. the citizens were allowed to build an embattled wall of stone around the city, for which they had a grant of six years toll on the wine, malt, oxen, hogs, calves, and sheep, consumed within the city. The first stone of this wall was laid in 1355, and it was afterwards completed with great strength and magnificence, being defended by 32 towers and 12 gates. Great part of the wall, most of the towers, and several of the gates, were ordered to be demolished in 1661, by Charles II. as a punishment for refusing admittance to Charles I. in 1642, and adhering to the parliament during the civil war.

Henry IV. held a parliament at this place in 1404, which old historians denominate *parliamentum indoctorum*, because all persons learned in the law were expressly excluded from seats, or because its acts were considered by the clergy, the historians of the age, as hostile to their interests and immunities. Another parliament held here in 1459, by Henry VI. was called *parliamentum diabolicum*, because of the numerous attainders it passed against the adherents of Richard Duke of York.

Previous to the Norman conquest, the diocese of Litchfield and Coventry included Chester, and after that event the see was removed to Chester. In the reign of William Rufus, the see was again restored to Coventry, where the bishops had a palace, no vestige of which now remains. At present the residence of the bishop is at Litchfield, and Chester is a separate bishopric. In the king's books, the bishopric of Litchfield and Coventry is rated at L.2800 yearly.

The population of this city was returned as 16,034 persons, of all ages and both sexes, in 1801, under the authority of parliament, though former calculations led to an estimate beyond 20,000, and some have even computed the number at 25,000. It is said to have contained 15,000 in the early part of the reign of Henry VIII.; but to have suffered so severely by the dissolution of its priory and monasteries, as to have been reduced in the reign of Edward VI. to 3000; but, by an exact enumeration taken in 1520, and recorded in the city leet book, the population was then 7000. About 3000 of the inhabitants are free burgesses, having votes in the election of two representatives to parliament.

The following abstract of the population of the *city of Coventry* is taken from the recent returns for 1811.

Inhabited houses,	3448
Families that occupy them,	4096
Houses building,	12
Uninhabited houses,	50
Families employed in agriculture,	123
Ditto in trade, manufactures, &c.	3207
Families belonging to neither of these classes,	766
Males,	8197
Females,	9726
Total population,	17,923

Coventry | Coulam.

The *county of the city of Coventry* includes the parishes of Anstey, Exhall, Foleshill, part of Sow, Stivichall, Stoke, and Wighen, and also the hamlet of Keresley.

The following abstract of the population of this county is also taken from the returns for 1811.

Inhabited houses,	1196
Families that occupy them,	1263
Houses building,	2
Uninhabited houses,	44
Families employed in agriculture,	290
Ditto in trade, manufactures, &c.	851
